The items suspended for consideration of the Commission by Mr. McKinstry under this heading are as follows:

"General Law Expenses:	1939	1938	1937
W. A. Vinson, Houston, Texas	$ 3,240.00	$3,240.00	$ 3,240.00
Vinson, Elkins, Weems & Francis, Houston, Texas	16,488.39	1.39	11,259.57
C. H. Keffer, Amarillo, Texas			590.77
Adkins, Pipkin, Madden & Keffer, Amarillo, Texas	6,625.76	4,379.96	9,185.11
L. M. Fisher, Amarillo, Texas	500.00		
Long, St. Lewis & Nyce, Washington, D. C.			55.36
Miscellaneous	27.86	14.65	
Totals	$26,882.01	$7,636.00	$24,330.81"

Mr. McKinstry's explanation for these suspensions appears on pages 5, 6, 7, and 8 of Exhibit 168, as follows:

"For the most part, Respondent's records, together with supplementary information obtained, do not sufficiently disclose the purposes for which legal services were engaged. Also, the charges represent principally

allocations charged to Respondent by associated companies. It has not been possible to determine the exact basis nor otherwise to arrive at any conclusion as to the reasonableness of such charges or allocations. In view of the foregoing circumstances, all general law expenses contained in the Respondent's operating expenses, as adjusted, have been included in this suspension.

"Examiner's comments relating to the above classes of items are as follows:

Re: W. A. Vinson and Vinson, Elkins, Weems & Francis

"Mr. W. A. Vinson is a member of the firm of Vinson, Elkins, Weems & Francis.

"Below are quoted paragraphs as numbered on page 2 of letter dated April 23, 1940, received from Mr. P. C. Spencer, Vice President of Canadian River Gas Company, in response to Examiner's request concerning charges for 1939 legal services:

"'(2) Vinson, Elkins, Weems & Francis, Houston, Texas.

"'The vouchers listed . . . represent fees and expenses paid to the above firm for legal services rendered by members of the firm on behalf of the Company during the year 1939. Such services were performed principally in connection with legislative matters relating to taxation, conservation and proration of natural gas production in the Texas Panhandle Field, in which the Company is vitally interested. In addition to legislative matters, during the year members of the firm also appeared on behalf of the Company before state boards and agencies with respect to various miscellaneous matters affecting the Company's business and affairs. While the firm has heretofore represented the Company in litigated matters, and is retained for that purpose, it was not called upon to do so during the year 1939.'

"'(3) W. A. Vinson

12 monthly payments of $270.00 each for retaining fees.

"Mr. Vinson's legal firm has been retained by the Company over a period of years. The above mentioned payments, which were made to Mr. Vinson for the account of his firm, represent the annual retainer fee for the services mentioned in item (2) supra." (Full fee is $300.00 monthly; $30.00 monthly is invoiced to Red River Gas Company.)

"Charges to Canadian River Gas Company for annual retainer fee and for special services constitute 90% of the total charges rendered, the other 10% having been invoiced to Red River Gas Company. This division follows the practice outlined in the second paragraph, page 2 of Mr. P. C. Spencer's (Vice President of Canadian River Gas Company) letter dated March 11, 1940, addressed to Examiner, which reads in part:

"* * * Southwestern Development Company has two subsidiaries engaged in production of natural gas in the Texas Panhandle Field—Canadian River Gas Company and Red River Gas Company. It has been the practice over a period of years to divide between these two companies any general expense involved in the protection of their mutual and common interests as gas producing companies, on a basis of 90% to Canadian River and 10% to Red River, which is estimated to represent the proportionate relationship of their interests; * * *"

Re: C. H. Keffer and Adkins, Pipkin, Madden & Keffer

"Mr. C. H. Keffer is a member of the firm of Adkins, Pipkin, Madden & Keffer.

"Practically all of the above charges have been received through Amarillo Oil Company acting on behalf of associated Southwestern Development Company subsidiaries and, in this connection, the third and fourth paragraphs of Mr. P. C. Spencer's March 11, 1940, letter to Examiner are quoted:

"'Over a period of years the law firm of Adkins, Pipkin, Madden & Keffer has been retained to repre-

sent all subsidiaries of Southwestern Development Company operating in the Texas Panhandle District. One lump sum retainer fee (now $10,000.00 per annum) is paid for all companies included in the arrangement. The retainer fee is divided between the several companies represented in proportion to the time devoted to office and routine business of the respective companies. The record of time so spent is kept by the firm and the allocations resulting therefrom have been changed from time to time to conform substantially to such record.

"'The retainer fee referred to above covers only normal office and routine work. Whenever other services are performed which involve only one company, all expenses and fees, in connection therewith are charged direct to that company; * * * Whenever separate services are rendered for more than one company on the same trip, all expenses and fees, if any, in connection therewith are allocated between such companies in proportion to the amount of time devoted to their respective businesses; * * * Whenever services are rendered in connection with a common interest of more than one company, the expenses and fees, if any, for such services are allocated between such companies in proportion to their respective interests; * * *'

"Joint direct conversations with representatives of Amarillo Oil Company and Mr. C. H. Keffer were had in an endeavor to obtain an understanding of the legal services rendered and the allocation of charges therefor to Canadian River Gas Company and other companies associated with it. Examiner Luttring's notes on these conversations read in part:

"'The firm of Adkins, Pipkin, Madden & Keffer are paid a retainer fee of $10,000.00 per year (by Amarillo Oil Company in quarterly installments) for services rendered to the following companies:

Company	Functional Character of Business
Canadian River Gas Co.	Production
Amarillo Oil Co.	Transmission
Amarillo Gas Company	Distribution
Clayton Gas Co.	"
West Texas Gas Co.	"
Dalhart Gas Co.	"
Red River Gas Co.	Production
Panhandle Pipe Line Co.	Transmission
Parcomis Oil & Gas Co. (oil only)	Production

"* * * explained to Mr. Keffer that the invoices rendered to Canadian River Gas Company by Amarillo Oil Company for their portion of the retainer did not show the description of the work performed. Mr. Keffer produced a diary for the years 1938 and 1939 (1937 diary had been destroyed) in which a notation is made of the name of the company, number of hours and brief description of the work performed. Mr. Keffer pointed out that the hours shown are the actual hours of service performed either in conference or on work for the Company; it did not include his time for services preparing for opinions and other counsel to the companies.

"'The retainer fee is paid each calendar quarter by Amarillo Oil Company, which company prorates the fee on the basis of hours of service rendered to the respective subsidiaries participating in the fee. * * *

"'We requested permission to use the diaries to extract information related to Canadian River Gas Company, which request was at first granted but Mr. Keffer decided after we had returned to our office, to make typewritten lists of the diary notes. (These lists were duly obtained.)

"'The matter of lack of description of the character of expenses was also discussed and Mr. Keffer informed us that it has always been the practice of their firm to only account for the amount spent on out-of-town trips, the difference between his cash at the be-

ginning and end of the trip. We suggested he give us a letter stating the nature of the expenses charged to Canadian River Gas Company.'

"Mr. Keffer responded by letter, May 14, 1940, which in part reads as follows:

"'You are advised that the expenses include such items as transportation, hotel bills, meals, tips, taxicab fares, telephone and telegraph bills, and occasionally stenographic bills. When I transact business for more than one client on the same trip the expense account is prorated.'

Re: Other Charges suspended

	1939	1938	1937
L. M. Fischer	$500.00	.....	.....
Long, St. Louis & Nyce	.....	.....	$55.36
Miscellaneous	27.86	$14.65	.....
	$527.86	$14.65	$55.36

"The above amounts, though suspended, appear to be proper charges concerning which no fundamental questions are raised, hence it is the Examiner's recommendation that they be allowed as acceptable charges to gas operating expenses."

On cross-examination concerning this suspension Mr. McKinstry testified (Vol. XLVIII, pp. 6560, et seq.) that this suspension involves certain fees and expenses paid to attorneys by Canadian for the years 1937, 1938 and 1939; that he is not disputing the fact that these attorneys rendered services to the company or that these services were of value and were needed by the company, and that he is not indicating in any manner that the amounts paid for the services were unreasonable. He suspended these fees and expenses because the company records do not sufficiently disclose the purposes for which the legal services were engaged (p. 6561). He testified he was furnished information concerning these services by Mr. Spencer and was referred to Mr. Spencer's letters quoted above in Mr. McKinstry's explanation, and then stated that the principal

reason for suspending these general law expenses in their entirety was to put all of the expenditures for legal services in one account and to give the Commission opportunity to review all the expenditures of that sort, and, particularly, as to the payments to Vinson, Elkins, Weems & Francis of Houston, Texas, 90% of which were charged to Canadian and 10% to Red River Gas Company. He testified he had received an explanation of this division from Mr. Spencer (p. 6563), but wanted to place all the information before the Commission and did not ask for any further information than that secured from Mr. Spencer. Mr. McKinstry also testified that he had not asked for any further information as to the fees paid Mr. Keffer's firm (p. 6564), but he simply felt it was advisable to flag the whole transaction for the Commission's consideration, the reason largely being because the transactions involved allocations between associated or affiliated companies rather than any failure upon the part of Canadian to give him more information or data.

Suspension of Management and Supervision Fees and Expenses and Special Services.

This suspension appears on pages 9 and 10 of Exhibit 168. The amounts thereof and Mr. McKinstry's explanation are as follows:

"The amounts shown represent all charges made by associated companies other than for insurance and certain telephone services on a recognized cost basis, and the legal fees and expenses included in Suspension B above. The nature of the charges appears in the details supporting Examiner's entries providing segregation from the several accounts in which originally included by Respondent, to classifications shown above. A summary of charges by associated companies and reference to Examiners entries follows:

	1939	1938	1937
Amarillo Oil Company	$10,013.22	$ 9,902.16	$ 9,752.86
Southwestern Development Company	884.70	283.50	330.00
	$10,897.92	$10,185.66	$10,082.86
Examiner's Entry No.	R-178	R-179	R-180

For each of the three years there is included in management and supervision fees and expenses $7,500.00 charged by Amarillo Oil Company to compensate for services of R. E. Wertz et al. It is the Examiner's recommendation that these annual payments be disallowed in the cost of gas operations by reason of Respondent's failure to substantiate satisfactorily the reasonableness and exact nature of the charges.

"Mr. P. C. Spencer (Vice President of Canadian River Gas Company), in response to Examiner's request, submitted the following explanation regarding the annual charge of $7,500.00, in a letter dated March 11, 1940:

"'This is not a prorated charge. It is a lump sum payment made by Canadian River Gas Company to Amarillo Oil Company for various services rendered to Canadian River by R. E. Wertz and other members of Amarillo Oil Company's staff. The amount of the payment was agreed upon by representatives of Canadian River, Amarillo Oil and Colorado Interstate Gas Company in 1933. The amount agreed upon was estimated to cover the actual cost of services rendered and to be rendered. Since 1933 the services rendered have increased substantially, but the lump sum payment has not been changed.'

"Examiner Luttring visited offices of Amarillo Oil Company and endeavored to obtain further explanations regarding the annual charge of $7,500.00 but without satisfactory result, as indicated from his notes which in part read as follows:

"'Mr. Snyder (General Auditor, Amarillo Oil Com-

pany) refused to give us any information other than that covered in the letters of Mr. Spencer and offered to give us no information until permitted to do so by Mr. Spencer.'

"Examiner Luttring wired Mr. Spencer as to whether Mr. Snyder might furnish names and salaries of individuals and amount of time by character of service performed for Canadian River Gas Company and received the following answer by wire on May 14, 1940:

"(Examiner) 'Luttring's wire yesterday $7,500.00 fee includes substantial services performed for Canadian by Moody, Baird, Spencer and their respective office forces therefore Snyder cannot give complete answer the charge is so small in view of the total services rendered it would seem to require little if any substantiation however Luttring wants additional details suggest he cover by writing me further letter of inquiry simplified as much as possible bearing in mind we have not maintained any job or time records please advise further wishes.'

"Examiner Luttring's notes further show:

"'In discussions with Mr. Snyder and from records which we were permitted to examine it was learned that Amarillo Oil Company carries a group of accounts under "Special Administrative Department." Mr. Snyder informed us that salaries of Mr. Wertz, Mr. Snyder and other employees who devote their services to the various subsidiaries under the jurisdiction of this special administrative department are charged to the special department as well as expenses of these employees.

"'Mr. Snyder stated that the fee of $7,500.00 charged to Canadian River Gas Company was first deducted from the expenses of the Special Department and the balance then prorated to the other subsidiaries participating in the services of those in the Special Department.

"'We asked Mr. Snyder the extent to which we could get data representing the expenses related to the

fee of $7,500.00 and his reply was that no information could be divulged except on advice of counsel.

"'Mr. Snyder does not deny that the books of Amarillo Oil Company contain most of the expenses, * * * which relate to the fee of $7,500.00 * * *.'

"'The remainder of amounts included in this suspension appear to be reasonable and proper charges to gas operating expenses and, in the opinion of the Examiner, should be passed accordingly.''

On cross-examination with reference to this suspension, Mr. McKinstry stated (Vol. XLVIII, pp. 6566, et seq.) that the suspension involves management and supervision fees and expenses and special services rendered to the Canadian River in the years 1937, 1938 and 1939 by Amarillo Oil Company and Southwestern Development Company. The Southwestern Development Company items do not involve fees of any character but are primarily for reimbursement on traveling and other expenses incurred for Canadian, and are so indicated on the records. The principal item suspended is a charge made by Amarillo Oil Company to Canadian of $7500 per year covering general administrative services rendered to Canadian by Amarillo Oil Company. It is indicated that this charge is for various services rendered by R. E. Wertz and other members of Amarillo Oil Company's staff. Mr. McKinstry states he is not questioning that Amarillo Oil Company and Mr. Wertz and others of the Southwestern Development Company group rendered general administrative services to Canadian (Vol. XLVIII, p. 6568), and he is not questioning that the services are of value or that the $7500 per year charge is unreasonable or excessive. There is no indication in the books and records of Canadian that Mr. Spencer ever received any direct payment as Vice President or Director or counsel for the company, or that Mr. N. K. Moody, President and Director of the company, received any direct payment for services he rendered the company, and the same is true as to Mr. George Baird, the Secretary and Treasurer and Director of the company. Mr. McKinstry's attention was then called to the information which Mr. Spencer had furnished him,

which is set forth in the above quotation from Exhibit 168 as to the services rendered for the $7500 annual fee.

MR. MCKINSTRY further testified as follows: (Vol. XLVIII, pp. 6566-6570.)

By Mr. Spencer:

Q. Let's go to the next mentioned item, Mr. McKinstry, and that involves management and supervision fees and expenses and special services rendered to the company in the years 1937, 1938 and 1939 by Amarillo Oil Company and Southwestern Development Company.

A. That is correct.

Q. Now, there are no fees—

The Trial Examiner: What page is that on, Mr. Spencer?

Mr. Spencer: Sir?

The Trial Examiner: What page is that on?

Mr. Spencer: Page 9.

Q. Now, there are no fees of any character involved in payments made to Southwestern Development Company, is that correct?

A. No, there are none.

Q. Any charges made by Southwestern Development Company to Canadian River primarily for reimbursement on traveling and other expense that I may have incurred for Canadian River or Mr. Baird may have incurred?

A. That is true.

Q. Those items are items of expenses on behalf of and incurred on behalf of Canadian River?

A. As so indicated by the records.

Q. And no fees there by Southwestern Development Company for Canadian River?

A. None.

Q. Now, that takes care of that. The principal item which has been included in the charges made by Amarillo Oil Company to Canadian River is the payment of $7500 per year covering general administrative services rendered to Canadian River by Amarillo Oil Company, is that correct?

A. The only indication we have is services of R. E.

Wertz, et al. That is the extent of the description we have of the item.

Q. Did I furnish you with an explanation with respect to that item? I think you will find it next to the last paragraph on that page.

A. That is true. It is indicated there that various services rendered by R. E. Wertz and other members of Amarillo Oil Company's staff—

Q. Well, I don't think it is necessary to read that into the record. It is in your exhibit and it speaks for *it*-

A. Yes.

Q. You aren't questioning that Amarillo Oil Company and Mr. Wertz and others of the Southwestern Development Company group rendered service to Canadian River,—I mean, general administrative services?

A. No, I am not questioning that.

Q. You are not questioning that the services are of value?

A. No.

Q. And you aren't indicating in any manner that the payment of $7500 per year is unreasonable or excessive?

A. No.

Q. Did you find any place in your examination of the books and records of the Canadian River Gas Company that I ever received any fee or salary or any other character of compensation from the Canadian River Gas Company?

A. There is no indication of any direct payment having been so made.

Q. No payment to me as Vice President or Director or Counsel for the company that you found in its books and records?

A. No, I found none.

Q. And similarly, did you find any such payment to Mr. N. K. Moody, President and Director for the company for the services he renders to the Canadian River Gas Company?

A. No, I don't recall having seen any, speaking of the last few years.

Q. Now, is that also true of Mr. George Baird who is Secretary and Treasurer and a director of Canadian River Gas Company?

A. That is true.

Q. Now, I believe you have it in here some place where

I explained to Mr. Luttring in a telegram that the $7500 fee paid annually by Canadian River to Amarillo Oil Company includes—this is on Page 10, third paragraph—includes substantial services performed for Canadian River, performed by Moody, Baird, Spencer and their respective office forces. You knew that?

A. That's right, yes.

Q. If I told you, Mr. McKinstry, that during the past year, or let me say during the year 1939, approximately one-third of my time was devoted to the business and affairs of Canadian River Gas Company, particularly in connection with this rate proceeding and that whatever those services were worth to Canadian River Gas Company was included in this $7500 that you have set up here, would you say that was unreasonable?

A. Why, I don't think it would be my place to pass judgment. It sounds—

Q. You mean you don't know how to evaluate my services?

A. I wouldn't attempt to. I'm afraid—

Q. Well, if that were true, can't you say that $7500 would be a pretty reasonable price for all these services that are rendered by those of us who are in Southwestern and Amarillo Oil Company?

A.—I don't think it would be within my province. I don't think I could honestly say.

Q. Well, I'm going to leave it up to the Examiner and I won't press you any further.

Suspension of Items Charged to Expense Claimed as Cost of Gas Plant in Report of Ford, Bacon and Davis, Inc., Dated April 15, 1940

This item of suspension appears upon sheet 11 of Exhibit 168 and involves the following amounts:

1937	$10,129.23
1938	9,293.47
1939	16,576.40

Mr. McKinstry's explanation of this suspension, on sheet 11, is as follows:

"Certain general and administrative expenses for the years 1937, 1938 and 1939, now claimed by the Respondent as gas plant capital expenditures, are suspended in order that the expenses so claimed may be directed to the attention of the Commission and its staff. The report of Ford, Bacon & Davis, Inc., covering the claim for restatement of plant has been filed with the Commission by the Respondent."

In further explanation of this suspension Mr. McKinstry, on cross-examination (Vol. XLVIII, pp. 6570, et seq.), stated that Mr. Lusk, in an exhibit introduced by the respondent through him, indicated these items should be capitalized, and that what he is doing here is calling the item to the attention of the Commission so that it would not be included both as capital and as an operating expense. Mr. McKinstry stated he was making no findings with respect to this particular item nor any recommendation.

Rate Case Expense

This is a 1939 item appearing on sheet 11 of Exhibit 168 involving $54,600.61. Mr. McKinstry's explanation on sheet 11 follows:

"Respondent charged to expenses on its books amounts expended incident to rate case pending before the Commission. Examiner's reclassification entry R-139 transfers such expenses under the balance sheet caption 'Deferred Debits' as of December 31, 1939, for the purpose of suspending the items for such disposition as the Commission may prescribe. Analytical details of the expenses thus suspended are contained in Schedule A-12 which appears in the exhibit relating to the balance sheet as of December 31, 1939."

In further explanation of this item MR. MCKINSTRY testified as follows: (Vol. XLVIII, pp. 6571, 6572.)

Q. All right, Item E, which involves the suspension of the rate case expenses incurred by the company in the amount of $54,600.61.

A. That is correct.

Q. You are taking this out of the income statement account?

A. That is correct.

Q. It is more than a suspension, then, isn't it?

A. It is placed in the deferred debit section on the balance sheet.

Q. That is more than a suspension, isn't it?

A. Yes, and this merely has reference again to that amount which is deferred.

Q. Well, then, you have done something with it. That is, you have taken out that item as an operating expense and you have put it in the deferred debits on the balance sheet and you have flagged the whole business?

A. That is right.

Q. I assume you do that upon the theory that whatever our proper expenses may be in this rate proceeding they may be amortized over some period?

A. As determined by the Commission.

Q. Yes, as determined by the Commission. You aren't attempting to fix any rate or amortization?

A. No.

Federal Income Tax.

This suspension likewise appears on Sheet 11, Exhibit 168, in amounts as follows:

1937	$63,735.69
1938	68,434.88
1939	66,403.02

Mr. McKinstry's explanation on sheet 11 follows:

"Income taxes for the years 1937, 1938 and 1939, as adjusted, are suspended for the reason that the income received by the Respondent, and which constituted the basis for assessment of its income taxes, may, as a result of this proceeding, be found to have been in excess of a fair return. The Examiner recommends that expenses chargeable to the ratepayer include, with respect to income taxes, only such an amount as would represent the necessary taxes required to be paid based upon income which the Commission determines it is proper for the Respondent to earn."

Further explaining this suspension (Vol. XLVIII, pp. 6572, et seq.), Mr. McKinstry stated that these figures are the company's book figures as related to these particular years, but not as taken up on the books in those years. The books, however, disclose that these amounts were paid for these years and no adjustment changing the amount as related to any year has been made. Mr. McKinstry does not have in mind that the Commission would enter any order in this proceeding that would serve to take away from or add to the company's net income for these years 1937, 1938 and 1939, and the purpose of this suspension is to call this particular situation to the Commission's attention in any analysis of past revenues and operating expenses it may make for comparative purposes. He does not contemplate that by this suspension there would be any changes on the books of account of the company, and that same situation is true generally with respect to all the income accounts as kept by the company for these particular years which Mr. McKinstry has shown in this exhibit. To Mr. McKinstry's knowledge there is no order of the Commission outstanding at the present time which requires the company to reclassify and adjust these income accounts.

Substitution of Depreciation and 6% Return on Investment for Amortization of Debt Included in Payments Made by Canadian to Texoma Natural Gas Company in Connection with Joint Operation of the Fritch Gasoline Plant.

This is the item included in the adjustments and deductions from operating expenses in Exhibit 168 (sheet 95) which, by stipulation of counsel during the course of the hearing (Vol. XLVIII, pp. 6575-6577), was eliminated from the adjustment items and incorporated into the items suspended for the Commission's decision. This entry is explained by Mr. McKinstry on sheet 95, Exhibit 168, as follows:

"To adjust 1937, 1938 and 1939 charges for interest and amortization of debt made to Respondent by Texoma Natural Gas Company in connection with joint operation of latter's Fritch gasoline plant. Depreciа-

tion and 6% return on investment are substituted in this entry in place of interest and amortization in accordance with data supplied by the Chicago regional staff of the Division of Accounts as per schedules attached to letter of Mr. R. M. Lindsay, Examiner in Charge, Chicago region, to Mr. W. E. Baker, Chief Accountant, dated August 1, 1940, copy of which is attached hereto. Summary of adjustment follows:

Item	1939	1938	1937
Bond, amortization and interest	$29,044.49	$22,721.39	$24,907.52
Depreciation	$ 5,739.31	$ 5,654.45	$ 5,574.07
Return on investment	11,582.87	11,656.59	11,785.67
	$17,322.18	$17,311.04	$17,359.74
Net reduction	$11,722.31	$ 5,410.35	$ 7,547.78

Testifying further as to this entry (Vol. LXVIII, pp. 6512, et seq.), Mr. McKinstry stated that this entry is a reclassification of charges paid by the company to the Texoma Company representing interest and amortization of debt in the gasoline plant of the Texoma Company which is a part of the leased facilities of the Canadian Company. The Canadian leases a portion of the gasoline plant facilities of the Texoma Company located near Fritch and has an operating contract with the Texoma Company, a copy of which is set forth at pages 13-16, Exhibit 168. Mr. McKinstry testified that under that contract, as a part of the rental which the Canadian pays for the gasoline plant, there is included a portion of the interest and amortization of the debt of Texoma on that plant.

Section 6 of the October 15, 1935 operating contract between the Texoma Company and Canadian (pp. 13 and 14, Exhibit 168), provides, in part as follows:

"Section 6. Canadian River shall be charged by Texoma with certain proportions of the total cost of

operation and maintenance of, and interest and retirement charges on, said gasoline plant as follows:

* * * * * *

"(b) Twenty-five per cent (25%) of the interest and of the sinking fund and/or other retirement charges on all bonds, notes or other indebtedness of Texoma from time to time outstanding, the proceeds of which have been invested in the said gasoline plant; provided, however, that in the event the said plant is abandoned on account of obsolescence or otherwise Canadian River shall pay to Texoma twenty-five per cent (25%) of the unamortized investment of Texoma in the said gasoline plant and Canadian River shall not thereafter be required to pay any additional amounts under this subdivision (b) with respect thereto."

Mr. McKinstry then testified (Vol. XLVIII, p. 6514), that in his Entry 182 he has not followed the contract, but has set up the account on an entirely different basis; that there is no intention on his part to establish some new contractual relation between the companies, but he is setting it up on what he considers a proper cost basis. He then stated (p. 6515) that the entire accounting by the Texoma Company for the operation of its gasoline plant and its subsequent settlement with Canadian is a part of the suspension that appears in Statement B4 abstracted above so that the entire settlement is subject to the findings in the investigation in which the Texoma Company is subject to now. Mr. McKinstry testified that the Canadian owns no part of these facilities and that he has set up his entry on the basis of a return to the Texoma Company on its investment at 6%; that this 6% is predicated upon information obtained from him through the Chicago regional staff (Vol. XLVIII, pp. 6516-6517), this information being contained in a letter dated August 1, 1940, from R. M. Lindsay, Examiner in charge of the Chicago region. There is no specific provision in the code guiding him in the making of this entry as he has done it. The basic consideration involves the cost included to represent decline in service value of the gasoline plant with the amounts themselves supplied by Mr. Lindsay, with the contract ignored. He has looked at the matter purely from an accounting stand-

point as to the determination of cost, and not from the standpoint of the contract provisions (p. 6522).

Again (Vol. XLVIII, pp. 6526, et seq.), Mr. McKinstry restated that he had substituted a new method of computing cost from that contained in the contract by substituting depreciation for amortization provided for in the contract.

Mr. McKinstry did not determine the depreciation rate used in his computation nor the 6% return on investment rate, but adopted someone else's figures (p. 6528). He has not examined the records of the Texoma Company. His whole calculation has been made and determined by persons other than himself (p. 6530) in another proceeding which is now pending before the Commission, and there is no evidence in this proceeding on that subject. His idea of making this adjustment originated with himself.

On redirect examination (XLVIII, pp. 6575, et seq.), Mr. McKinstry stated that the principles involved in this adjustment or suspension would have been recognized, notwithstanding receipt of the basic information from the Commission's Chicago regional office, and that this suspension could have been made without having to rely upon the information alone received from the Chicago office. As above pointed out, it was then stipulated (pp. 6576, 6577) that this entry should be suspended for consideration of the Commission.

MR. MCKINSTRY also prepared and submitted Commission Exhibit 169, "Balance Sheet of Canadian River Gas Company," and in connection therewith testified as follows: (Vol. XLVIII, pp. 6580-6585.)

A. "This report consists of a balance sheet of the Canadian River Gas Company as at December 31, 1939, and six supporting schedules.

"Statement A-1 shows the balance sheet per the company's books, reclassifications and adjustments of items contained in it, which were made by the Examiner, and the balance sheet as adjusted. The six schedules include one that summarizes the Examiner's reclassification and adjustment entries, one that nets amounts receivable from

and amounts payable to associated companies, one that shows the Examiner's analysis of the 1939 rate case expenses, which have been transferred to Deferred Debits, and three that support and explain other items on the balance sheet, namely, Deferred Debits—Others, long-term debt, and surplus.

"The first schedule, A-10, shows the Examiner's adjustments and reclassifications in summary form and their application to the various balance sheet items affected; it gives a brief description of each entry and designates it by number. The entries, themselves, are not given in this exhibit, with the exception of Entry No. R-1 shown in Schedule A-11, but are to be found in other accounting studies, prepared by members of the Federal Power Commission staff, which will be offered in evidence in this case.

"Entries in the '100' series are shown in Schedule B-16 of the study entitled 'Income Accounts and Supplemental Data, Including Examiner's Reclassifications of Adjustments;' entries in the '200' series are shown in the study entitled 'Gas Plant Accounts and Examiner's Adjustments:' and entries in the '400' series are shown in the study entitled 'Annual and Accrued Depletion and Depreciation of Gas Plant and Examiner's Adjustments.'

"The reclassification and adjustment debits and credits made against Balance Sheet Accounts on Statement A-1 are the footings of the columns in Schedule A-10, each of which columns represents a balance sheet account and contains all the debit or credit entries affecting the account it represents.

"Schedule A-11, which is Adjustment Entry No. R-1, is a tabulation showing the balances receivable from each associated company offset against the balances payable to each of these companies, and vice versa. This schedule was prepared for the purpose of developing for the balance sheet the net amounts receivable from and payable to associated companies.

"Schedule A-12 is an analysis of 1939 rate case expenses amounting to $54,600.61. These expenses are carried in the balance sheet as a deferred debit. In addition to showing the nature of each rate case expense item, this schedule also

shows the account to which the items were charged by the company. They were all transferred to the balance sheet account 'Other Deferred Debits' by Examiner's Entry No. R-139 and the total amount of them represents Expenses Suspended for Further Consideration of the Commission (cf. Statement B4 of Report on Canadian River Gas Company Income Accounts).

"'Included in the total is $23,790.97 representing the cost of a valuation report and a physical inspection of the Respondent's properties made by and under the direction of Ford, Bacon & Davis, Inc., Consulting Engineers. This firm billed for its work at cost of services, plus ten per cent, plus overheads of approximately 75 per cent, and plus expenses at cost.

"'Schedule A-13 sets forth the particulars of the account 'Deferred Debits—Other,' shown on the adjusted balance sheet at December 31, 1939, in the amount of $34,519.70. The amount which is classified on the company's books as a memorandum account, only, represents revenue receivable in the future from Amarillo Oil Company, pursuant to terms of sales contracts with that company, which are explained in this schedule. The adjustment necessary to place this item on the balance sheet was made in Examiner's Entry No. 133 The books show that as of August 31, 1940, the balance in the Deferred Debit Account was $14,151.25, or $20,368.45 less than the balance on December 31, 1939.

"Schedule A-14 shows the total amount of the company's twenty-year bonds, dated June 1, 1928, that have been issued, the amount of them that have been redeemed, and the balance of them outstanding on December 31, 1939. It also shows the amount of its promissory notes outstanding.

"All the long-term debt, both bonds and notes, has been issued to and is held by Colorado Interstate Gas Company. The bonds were issued during 1928 and 1929 at 100 in the total principal amount of $11,000,000, and bear interest at six per cent per annum. From 1930 to 1939, inclusive, $5,943,000 of them in principal amount have been redeemed, leaving outstanding as at December 31, 1939, $5,057,000. Bonds are redeemable at a premium, semi-annually, to June 1, 1948.

"The notes payable have been issued from month to month since 1928 to finance current construction after the exhaustion of the funds provided by the sale of bonds; they bear interest at the rate of six per cent per annum. Each note is payable in equal monthly instalments over a period not to exceed 120 months nor to extend beyond May 31, 1948, whichever is the shorter period.

"Schedule A-15 shows forty-two Examiner's adjustments and reclassifications of the Surplus Account that increase the balance of that account, as of December 31, 1939, from $3,609,943.09 to $5,826,298.70. These entries are the same as these shown in Column 17 of Schedule A-10. They are reproduced in Schedule A-15, so that they may be more conveniently referred to, and to provide a reconciliation of the balance of the Surplus Account, per books, with the balance as adjusted by the Examiner."

Q. Mr. McKinstry, in the preparation of this Exhibit No. 169, you had available for your inspection the books and records of the Canadian River Gas Company?

A. I did.

Q. And what records did you use in the preparation of this exhibit with reference to the Canadian River Gas Company?

A. You mean in respect to the company's records?

Q. Yes.

A. Or referring to our—

Q. No, the company's—in other words, you got your figures from the company's books and records and then whatever adjustments you had to make, you of course made them?

A. That is correct.

Q. And after the exhibit—or, rather, after the basic material had been gathered by you for the preparation of this exhibit and before it was finally reproduced, I will ask you whether on the title page there appears the signatures of Mr. Kenneth L. Smith in charge of field assignment; Mr. Harold L. Tomlin, Examiner in charge of regional office, and Mr. Charles W. Smith, chief, Bureau of Accounts finance and rates; is that correct?

A. That's right.

Q. And all of those men are presently connected with the Federal Power Commission in those capacities?

A. That is right.

Q. And were at the time they affixed their signatures to that page?

* * * * *

On cross-examination MR. MCKINSTRY further testified: (Vol. XLVIII, pp. 6586-6590.)

A. It is. That is, to the point of summarization in a large part from other exhibits.

Q. And with the exception of one reclassification entry which you have put in here, the balance sheet as you have constructed it here represents merely a recapitulation of the work done in Exhibit No. 168?

A. And as affected by the previous exhibit, I believe, on the utility plant accounts.

Q. Yes, I should have included Exhibit 146.

A. And one exhibit on the reserves for depreciation and depletion.

Q. Yes. Now, turn to Page 2 of Exhibit 169. Go down—which is the liability side of the balance sheet—

A. That is correct.

Q. Go down to Line 27 and you have an item there that is designated "Taxes Accrued", $549.55. To shorten it up I'll tell you that it is my information that that particular item is not accrued taxes but represents old age benefits payments made by employees and held by the company temporarily. Is that your understanding?

A. That is. Of course, that is a social security tax.

Q. But it is not a company tax?

A. That is true. It is not a company tax. It still is a tax accrued for and on behalf of the employes that has been collected by the company.

Q. Yes, but as to the employes, it is an accrued tax, but as to the company it is something that they owe the employes until it is paid, is it not?

A. Well, I believe the amount has been deducted from the—well, I won't go into the exact details.

Q. It is not a very large amount and I think we are agreed on what it is.

A. Yes, it is a social security tax.

Q. I wanted to ask you this question: This Entry No.

182 as set forth in Exhibit 168 is carried over into this balance sheet?

A. No, it is not.

Q. Can we leave it this way, Mr. McKinstry, if you feel it necessary to do so, please check that and if you find it carried over we ought to make some stipulation.

A. I can very definitely say that it does not.

Q. All right. Pages 3, 4 and 5 of Exhibit 169 carrying summary schedules of all of the reclassification and adjustment entries have been applied to this balance sheet?

A. That is correct.

Q. On Page 6 you have an Entry No. R-1. I assume the only purpose of that is to net the amount that may be a debit or a credit as between associated companies?

A. That is true.

Q. The company, perhaps on its books now or on its balance sheet perhaps has not netted those figures?

A. No, they have a receivable and a payable. They have each of those accounts shown whereas I have netted the respective balances to the one total.

Q. All right, Schedule A-11 on Pages 7 and 8, what is the purpose of that, Mr. McKinstry?

A. That is merely to give the detail of the entry of the one just referred to showing the balances per books, both receivable and payable and showing reclassifications of the respective balances.

Q. I think I mis-described that. I was talking about Schedule 8—no—yes, I should have said Pages 6 and 7 instead of 7 and 8 as I did.

A. Oh, yes.

Q. All right, now, we come to Schedule A-12 which consists of five pages commencing on Page 8, and that is an analysis of the '39 rate expenses which you have transferred to other deferred debits as of December 31, 1939 and also suspended?

A. That is correct.

Q. In Exhibit No. 168.

A. Yes.

Q. Now, these are the rate expenditures as you found them on the books for the year 1939, Mr. McKinstry?

A. I believe that there have been some slight changes from—these are all shown per the books, although we have made some slight reclassifications, I believe.

Q. Those are rather inconsequential?

A. They are not of major proportions.

Q. Now, the classification of these suspensions as you have shown in Columns 6 to 12, inclusive, is that your classification?

A. That is, yes.

Q. You classified them and distributed them from the information appearing on the voucher, I presume?

A. That is right—endeavored to do so.

Q. Now turn to Page 13, your Schedule A-13, the second paragraph commencing on Page that starts off this way:

"The original sales contract with Amarillo Oil Company, dated June 3, 1928." I believe that date you have there is a typographical error and I believe perhaps you or counsel will want to correct it.

A. It should be January 3, 1928.

Mr. Lange: It should be January 3, 1928 instead of June.

The Trial Examiner: Do you wish to make that correction in your exhibit?

The Witness: Yes, I do.

The Trial Examiner: Very well, the reporter will be directed to physically make such correction.

By Mr. Spencer:

Q. Your Schedule A-15 commencing on Page 15 merely is a reconciliation of earned surplus per books as reclassified and as adjusted?

A. That is correct.

Q. Which I presume makes the balance sheet complete in any event?

A. That is true.

Said Exhibit 169 is in part as follows:

CANADIAN RIVER GAS COMPANY

BALANCE SHEET

DECEMBER 31, 1939

Line No.	Assets and Other Debits (1)	Per Books (2)	Examiner's Reclassifications and Adjustments Debit (3)	Credit (4)	As Adjusted (5)

With respect to balances as of December 31, 1939 with associated companies, (1) to apply against balance receivable the balance payable when latter balance is less than that of the former, (2) to apply against balance payable the balance receivable when latter balance is less than that of the former. Summary of net balances follows on sheet 2 of this schedule.

Exhibit No. 169

ket G-124

Schedule A-13
Sheet 1 of 1

CANADIAN RIVER GAS COMPANY
DEFERRED DEBITS - OTHER
DECEMBER 31, 1939

13

The entire amount hereunder relates to the prospective sum coverable from Amarillo Oil Company on billings for natural gas livered to that company since July 1, 1931 through December 31, 1939.

The original sales contract with Amarillo Oil Company, dated 3, 1928, provides that deliveries of natural gas will be settled on a rate per MCF ascertained in accordance with provisions stipulated the aforementioned contract. By a supplemental agreement dated ly 1, 1931, natural gas sold to Amarillo Oil Company and in turn livered to facilities of Panhandle Pipe Line Company, is billed at cents per MCF rather than at the ascertained rate developed under the iginal contract of sale. On these particular deliveries the 4⅜ cent te per MCF is to apply until such time as this rate shall have enabled e Respondent to recover the deficiency in billing which occurs when e ascertained rate exceeds the revised rate of 4⅜ cents per MCF. The pplemental agreement provides that when the entire deficiency in lling has been offset, the supplemental agreement will be rendered rmanently inoperative and the rate ascertained in accordance with the iginal contract of sale will apply to all subsequent billings.

From July 1, 1931 and continuing through the year 1935, the certained rate was in excess of 4⅜ cents per MCF, and subsequent ereto the ascertained rate has been less than 4⅜ cents per MCF. The ount of $34,519.70 set up as a deferred debit in Examiner's entry . 133 represents the portion of the deficiency in billing during the riod July 1, 1931 to the end of 1935 which had not been offset as of cember 31, 1939, detailed below by periods:

d of Year	Amount of Annual Excess: Ascertained Rate over 4⅜ Cent Rate	Amount of Annual Excess: 4⅜ Cent Rate over Ascertained Rate	Cumulative Amount - Excess of Ascertained Rate over 4⅜ Cent Rate
1931	$22,939.11		$ 22,939.11
1932	39,582.77		62,521.88
1933	30,958.00		93,479.88
1934	26,616.56		120,096.44
1935	11,469.13		131,565.57
1936		$14,254.08	117,311.49
1937		29,903.86	87,407.63
1938		26,076.03	61,331.60
1939		26,811.90	34,519.70

CANADIAN RIVER GAS COMPANY
LONG-TERM DEBT
DECEMBER 31, 1939

14

First Mortgage and Collateral Trust Twenty Year Six Per Cent Sinking Fund Gold Bonds due June 1, 1948: (Note 1)

Date of Issue (At Par)	Principal Amount
June 27, 1928	$ 8,470,000.00
Dec. 3, 1928	740,000.00
Dec. 30, 1929	1,790,000.00
Total issued	$11,000,000.00
Principal amount redeemed between June 1, 1930 and December 31, 1939	5,943,000.00
Balance outstanding December 31, 1939 (Note 2)	$ 5,057,000.00

Promissory Notes (Note 1) 1,348,254.14

These notes have been issued from time to time to finance current construction after the exhaustion of the funds obtained from the sale of bonds. The notes are redeemable in equal monthly installments over a period of 120 months from date of issuance or by May 31, 1948, whichever is the shorter period. The notes bear interest at the rate of 6% per annum, payable semiannually on January 1 and July 1.

Total Long-Term Debt $ 6,405,254.14

Notes:

(1) All issued to and outstanding amount held by Colorado Interstate Gas Company.

(2) Semiannual provisions to a sinking fund are to be made to permit redemption of annual principal amounts as follows:

Year	Principal Amount
1940	$ 594,000.00
1941	595,000.00
1942	594,000.00

CANADIAN RIVER GAS COMPANY
RECONCILIATION OF EARNED SURPLUS PER BOOKS, AS RECLASSIFIED AND AS ADJUSTED
DECEMBER 31, 1939

Line No.	Examiner's Entry No. (1)	Description (2)	Debit (3)	Credit (4)
35	250-A	Reallocation of Clayton lateral overheads	$ 10,233.36	
36	400	To reverse depreciation and depletion accrued on Ingerton lease, No. 27, and wells	61,290.54	
37	401	To apply net loss on retirement of Ingerton lease, No. 27 and wells, to reserves		$ 51,374.07
38	402	To reverse erroneous charges to reserve for depletion	5,725.24	
39	403	To eliminate charges to reserve for depletion covering abandoned leases	37,950.32	
40	404	To reverse Respondent's total accruals in reserve for depletion		1,549,089.05
41	405	To set up revision of reserve for depletion of operated acreage	110,241.42	
42	406	To set up revision of reserve for depletion of intangible well costs	172,929.56	
43	407	To reverse Respondent's total accruals in reserve for depreciation		3,098,285.02
44	408	To set up revision of reserve for depreciation of gas plant	1,679,038.38	
45	411	To set up revision of reserve for depreciation applicable to Clayton lateral		3,532.73
46	412	To transfer to reserve for depreciation profit and loss on retirement of utility plant		100,168.67
47			$3,121,865.20	$5,948,165.90
48				3,121,865.20
49		Balance Adjusted		$5,826,298.70

Exhibit No. 169

35 33

169

MR. MCKINSTRY also prepared and submitted Commission Exhibit 175, "Comparison of Operations of Canadian River Gas Company for Nine Months Ended September 30, 1940," and "Balance Sheet as of September 30, 1940." With reference thereto MR. MCKINSTRY testified as follows: (Vol. XLIX, pp. 6815-6819.)

Q. Mr. McKinstry, did you in connection with the preparation of this Exhibit 175 also prepare a written statement setting forth in summarized form the principal items of the exhibit?

A. I did.

Q. Will you please read that statement into the record?

A. "The principal purposes of this exhibit, which relates to Canadian River Gas Company, are to present (1) a comparison of operations for the two nine-months periods ended September 30, 1940, and 1939, respectively; (2) the amount of expenditures incurred in connection with this proceeding, up to September 30, 1940; and (3) the changes in the investment in gas plant in service for the nine months ended September 30, 1940.

"The schedules comprising this exhibit are as follows:

"Schedule No. 1 Balance Sheet, as reclassified, September 30, 1940.

"Schedule No. 2 Gas plant in service, September 30, 1940.

"Schedule No. 3 Deferred debits—rate case expenses, September 30, 1940.

"Schedule No. 4 Statement of income and surplus accounts as reclassified for the nine months ended September 30, 1940, and 1939, and comparison.

"Schedule No. 5 Statement of operating revenues for the nine months ended September 30, 1940, and 1939, and comparison.

"Schedule No. 6 Summary of operating expenses as reclassified for the nine months ended September 30, 1940, and 1939, and comparison.

"The figures used in this exhibit are as shown by the company's books, as at the dates stated in the schedules. Only two reclassifications have been made: rate case expenses have been transferred from the income account to

the balance sheet, in order to classify them as deferred charges, and certain operating and non-operating expenses have been transferred from work in progress to the earned surplus account.

"Financial.

"Schedule No. 1, the balance sheet at September 30, 1940, reflects the balances as shown by the books except for the reclassifications explained above.

"Schedule No. 2 shows in summary form by accounts, additions to and retirements of gas plant in service and gasoline plant in service during the nine months ended September 30, 1940, which principally are as follows:"

Mr. Lange: You may just copy that into the record as a table, Mr. Reporter?

The Trial Examiner: Yes, it may be copied.

(At the direction of the Trial Examiner, the following table was copied into the record:)

Gas Wells	
211 Gas Well Equipment—Intangible	$14,574.33
212 Gas Well Equipment—Tangible	8,260.58
	$22,834.91
Main Compressor Stations	
Dalhart Station:	
218-C Land	429.87
221-C Structures	25,174.06
223-C Other Structures	10,932.81
224-C Equipment	187,489.07
	$224,025.81

The Witness: "The additions to main compressor stations account represent the construction and installation new of a compressing station and equipment, and bring the number of 600 H.P. Clark compressor units that the company has in service to five.

"Results of Operation.

"Net utility income for the nine months ended September 30, 1940, as shown on Schedule No. 4, is greater than net utility income for the nine months ended September 30,

1939, by $116,136.98. This increase is accounted for as follows:"

Mr. Lange: And may we have that table copied also?

The Trial Examiner: Yes.

(At the direction of the Trial Examiner, the following table was copied into the record:)

	Increase (Decrease) 1940 over 1939
Operating Revenues	$110,230.19
Operating Revenue Deductions:	
Operating expenses	$ 26,077.58
Depreciation	1,919.32
Depletion	4,385.29
(Profit) on plant retirements	(3,498.38)
Taxes	(16,779.81)
Total	$ 12,104.00
Net Operating Revenues	98,126.19
Exploration and Development Costs:	
Delay rentals	$ 12,155.91
Nonproductive well drilling	(30,166.70)
Total	$(18,010.79)
Net Utility Income	$116,136.98

The Witness: "Schedule No. 5 shows the increase of $110,230.19 in operating revenues by sub-classifications.

"Schedule No. 6 sets forth the increase of $26,077.58 in operating expenses by accounts. This increase consists chiefly of increases in gas well royalties.

"Taxes are less in 1940 chiefly because of the fact that in 1939 Texas advalorem taxes were paid in advance but in 1940 have not been.

"The decrease in nonproductive well drilling expense shown as $30,166.70, represents the entire amount expended in 1939; during the first nine months of 1940, $48,935.68 was similarly expended, but is classified by the company as profit

and loss suspense in Subschedule No. 6-1 and was not reclassified for the purpose of this exhibit.

"Miscellaneous nonoperating revenues classified under other income in schedule 14, line 16, is $83,624.65, less for the 1940 period than for comparable period of 1939. The decrease is due principally to the fact that the price per gallon realized from the sale of gasoline extracted from natural gas dropped approximately fifty per cent in 1940 below the 1939 price."

By Mr. Lange:

Q. Mr. McKinstry, in the preparation of this exhibit—strike that.

Does this exhibit reflect the figures as per company's books?

A. They are all according to the company's books.

Q. Were there any adjustments that appear on any figures that were obtained by you from those figures that appear in this exhibit?

A. The grouping perhaps does not correspond with the balances as shown on the company's books, nevertheless they are based upon the book balances without any adjustment.

Q. Without any adjustment?

A. That is true.

Q. You haven't made any, nor does this exhibit attempt to reflect any adjusted figures?

A. That is correct.

Q. But it is intended as a comparison to reflect the actual book figures of the company for those two operating nine-months periods?

A. That is right.

Q. Oh, yes, is there a reclassification anywhere in the exhibit?

A. Yes, there is.

Q. Will you point it out, please?

A. Page 1 which is Schedule No. 1, Line 3, "Construction work in progress" has been reclassified taking from it the amounts which the books contain relating to operating expenses as of September 30, 1940, and we have also treated the nine months ended 1939 in a similar fashion.

Q. Where is that shown? Doesn't the note on Page 2,

Note 2—or, rather, Note 1—Note 1 and Note 2 on Page 2 cover the reclassification that you have made?

A. No, the Note 1 only relates to the period ending September 1940—September 30th, 1940.

Q. And what does Note 2 refer to?

A. That is another reclassification which appears on Line 10.

Q. Of Page 1?

A. Of Page 1. That total amount is taken from the earned surplus account and placed in this balance sheet.

Q. That is the item identified as rate case expenses?

A. That is correct.

Q. With the Note 2 referring to it?

A. That is correct.

Q. Note 2 appearing on Page 2?

A. That is correct.

Q. Are there any other reclassifications in the exhibit, Mr. McKinstry?

A. No, those are the only two.

Q. And you have previously stated that you made no adjustments?

A. No adjustments.

* * * * *

On cross-examination MR. MCKINSTRY testified as follows: (Vol. L, pp. 6835-6840.)

Q. Mr. McKinstry, on Friday afternoon you submitted your Exhibit No. 175 which generally shows the comparison of operations of the Canadian River Gas Company for two 9-months' periods ending September 30, 1940 and 1939, respectively?

A. That is correct.

Q. As I recall your direct testimony with reference to that exhibit and also as indicated in your written statement, the figures shown in your balance sheet are book figures with the exception of two reclassifications which you have made?

A. That is correct.

Q. The first reclassification involves the transfer of rate case expense from the income account to the balance sheet in the form of a deferred debit?

A. Yes.

Q. You have taken that out, as I think was developed in a previous exhibit which you had for Canadian River?

A. Yes.

Q. So what you do here is merely to give effect on the balance sheet to what you did generally in your exhibit with respect to the income accounts of Canadian River?

A. Except to merely take the book figures only without any adjustment or major reclassification.

Q. Now, your written statement indicates that the second reclassification involves certain operating and non-operating expenses which have been transferred from work orders to work in progress to the earned surplus account?

A. That is correct.

Q. Now take your balance sheet as reclassified on September 30, 1940 which is on Page 1, Schedule No. 1, and indicate to me on the balance sheet where your second reclassification appears.

A. On Line 3, construction work in progress, the amount of $44,495.90 which is the amount remaining after we have removed $7,578.84 from it as indicated in Note 1 on Page 2 of Schedule No. 1.

Q. Yes. Now, in order to arrive at the figures shown in Line 3, Sheet 1 of Schedule No. 1, you had to make some reclassification between expense items and capital items, did you not?

A. Yes.

Q. And you used your own judgment in that regard?

A. The amounts were taken from the individual work order sheets in the work in progress ledger at Colorado Springs.

Q. Yes, I understand the amounts are the book amounts, but the classification of those amounts had been made by you as between expense and capital, is that not correct?

A. I believe the classifications are indicated on the work orders.

Q. Well, do you any place in this exhibit show the breakdown as between expense items and capital items in the work orders which you have involved in this reclassification?

A. It merely shows the amount which has been reclassified only.

Q. Well, would it be correct to say, then, that your classification of the various expenditures contained in the work orders which you mention here has been taken by you as indicated on the voucher?

A. No, as indicated—

Q. On the work order?

A. On the work order. I believe the work order ledger sheet has an indicated classification between expense and the expenditures for plant.

Q. In any event, what you attempted to do was to take the company's classification of those expenditures rather than to exercise your own judgment?

A. That is correct.

Q. I take it that one of the primary purposes of this exhibit as you have indicated in your written statement is to show a comparison of operations for the last two nine-month periods?

A. That is correct.

Q. Do you think that such a comparison can be best obtained by using a nine-months period rather than a twelve-months period ending on the date you want to use?

A. This happened to be the latest data we were able to assemble and get together for an exhibit. It is true that the more complete the period the more indicative and the more reliable is the information in comparative form with other annual periods.

Q. Well, you could have taken the twelve-months period in each instance preceding September 30th instead of the nine-months period, is that not right?

A. Taken twelve months ending—

Q. Yes.

A. That, of course, is something that could have been used, true enough.

Q. And in that event you would have had a full year's operations rather than nine months?

A. That is correct.

Q. And I believe you have indicated that for the purpose of comparison the full year would be preferable to nine months?

A. When I referred to that, it would be the twelve months of 1940 if it was all available.

Q. Yes. Now, for the purpose of comparison I take it

you have not included here any information that might show the differences in degree day deficiencies during these periods in the principal markets to which this gas of Canadian River Gas Company is transported and sold?

A. Will you repeat the question, please?

(The question referred to was read by the reporter as set forth above.)

The Witness: No, I have not.

By Mr. Spencer:

Q. Degree day deficiencies would have some bearing on the two periods for comparative purposes, would it not?

A. Well, as far as I am concerned, I am merely taking the factual information and comparing the two together.

Q. Well, then, is your answer that you do not know whether it would or not?

A. Well, I would say that it would, knowingly.

Exhibit 175, in part, is as follows:

Exhibit No. 175

Docket G-124

Schedule No. 1
Sheet 1 of 2

CANADIAN RIVER GAS COMPANY
BALANCE SHEET, AS RECLASSIFIED
SEPTEMBER 30, 1940

1

Line No.	Assets and Other Debits	
	Utility Plant	
1	Gas plant in service (Schedule No. 2)	$14,438,053.69
2	Gasoline plant in service (Schedule No. 2)	349,451.24
3	Construction work in progress (Note 1)	44,495.90
4	Total Utility Plant	$14,832,000.83
	Current and Accrued Assets	
5	Cash	$ 19,570.98
6	Notes receivable	305.00
7	Accounts receivable	183,649.12
8	Materials and supplies	98,308.71
9	Total Current and Accrued Assets	$ 301,833.81
	Deferred Debits	
10	Rate case expenses (Note 2) (Schedule No. 3)	$ 119,564.00
11	Other	3,151.58
12	Total Deferred Debits	$ 122,715.58
13	Total Assets and Other Debits	$15,256,550.22

	Liabilities and Other Credits	
14	Capital Stock - common capital stock 25,000 shares, no par value (all issued to Southwestern Development Company)	$ 1.00
	Long-term Debt (all payable to Colorado Interstate Gas Co.)	
15	First Mortgage and Collateral Trust Twenty Years Six Per Cent Sinking Fund Gold Bonds, due June 1, 1948	$ 4,760,000.00
16	Advances covered by promissory notes	1,401,133.38
17	Total Long-term Debt	$ 6,161,133.38
	Current and Accrued Liabilities	
18	Vouchers payable	$ 63,875.47
19	Accounts payable	356,671.00
20	Accrued liabilities	161.88
21	Total Current and Accrued Liabilities	$ 420,708.35
	Reserves	
22	Reserve for depletion	$ 1,725,481.02
23	Reserve for depreciation	3,148,898.06
24	Total Reserves	$ 4,874,379.08
25	Earned Surplus (Note 1 and 2)	$ 3,800,328.41
26	Total Liabilities and Other Credits	$15,256,550.22

Notes: (1) After reclassifying to Earned Surplus, operating and nonoperating deductions included in work in progress:

Total per books	$52,074.74
Total per this schedule	44,495.90
Total reclassified (see footnote Schedule No. 4)	$ 7,578.84

(2) The amounts shown under caption, "Deferred Debits - rate case expenses", are derived by reclassification from Earned Surplus as shown in footnote of Schedule No. 4:

Accumulated rate case expenses for the year 1939 as shown in Schedule A-12 of Exhibit on Balance Sheet and Supplemental Data	$ 54,600.61
Accumulated rate case expenses for nine months ended September 30, 1940	64,963.39
Total	$119,564.00

CANADIAN RIVER GAS COMPANY
STATEMENT OF INCOME AND SURPLUS ACCOUNTS - AS RECLASSIFIED
FOR THE NINE MONTHS ENDED SEPTEMBER 30, 1940 AND 1939 AND COMPARISON

Note: Earned Surplus in the foregoing statement is per books after addition thereto for rate case expenses deferred and deduction therefrom for operating and nonoperating deductions included in work in progress as set forth in the following detail:

	1939	1940
Earned Surplus, September 30:		
Per books	$3,388,703.88	$3,688,343.25
Per this schedule (above)	3,359,909.70	3,800,328.41
Net increase (decrease) in earned surplus	$ (28,794.18)	$ 111,985.16
Reclassified from earned surplus for the three months ended December 31, 1939 and from construction work in progress at September 30, 1940 to earned surplus:		
Operating Revenue Deductions		
Operating expenses:		
Production System		
W.O. 554		$ (3,417.40)
W.O. 569		(2,300.45)
Gathering System		
W.O. 522 closed October 1939	$ (223.88)	
Compressing Station		
W.O. 536 closed December 1939	(217.41)	
Transmission System		
W.O. 537 closed December 1939	(889.33)	
W.O. 538 closed November 1939	(490.60)	
W.O. 576		(385.15)
General		
W.O. 574		(587.56)
Telephone System		
W.O. 534 closed December 1939	(5.07)	
W.O. 564		(309.96)
	$ (1,826.29)	$ (7,000.52)
Exploration and Development Costs		
Nonproductive well drilling (Bivins A-26)	$ (30,166.70)	
Other Income		
Nonoperating revenue deductions		
Bivins Camp expense		
W.O. 498 closed November 1939	$ (397.21)	
W.O. 528 closed November 1939	(712.72)	
W.O. 536 reopened 1940		$ (289.16)
Shop expense		
W.O. 498 closed December 1939	(47.64)	
Gasoline expense		
W.O. 536 closed December 1939	(217.41)	
W.O. 536 reopened 1940		(289.16)
Total	$ (1,374.98)	$ (578.32)
Total reclassified from earned surplus	$ (33,367.97)	
Total reclassified from construction		$ (7,578.84)

Bivins A-26	$ 189.69		
City of Amarillo No. 1	48,746.08		
	$ 48,935.68		$ 48,935.68
Total	$101,190.56	$108,332.59	$ (7,142.03

56. Operating Costs of Canadian, 1928 to 1939, Inclusive, and as Estimated, 1940 to 1947, Inclusive, for all Gas, Except Colorado Interstate's Direct Sale Gas.

Exhibit 165, Witness Rhodes (Vol. XLVI, p. 6277), shows the cost of operations of Canadian for resale gas alone, 1928 to 1947, inclusive. Rhodes said that without the production of gas delivered to the Denver Line for sale direct to consumers, the resulting annual costs of Canadian's operations are lower than those shown in Exhibit 163, abstracted above, due to the reduction in the required production facilities set forth in Exhibit 121, Witness Watson, and a reduction in transmission facilities set forth in Exhibit 98, Witness Rhodes, as well as from the reduced volume of gas required. Savings in the cost of operations through the elimination of direct sale gas below those actually incurred in 1939 are stated to be as follows:

1.	Reduction in Total Expense, Column (4), due to reduced number of wells and volume of gas (which refers to Statement No. 1 of this exhibit)	$115,629
2.	Offsetting reduction in gasoline revenue due to reduced volume of gas, Column (5)	-85,078
3	Net Reduction in Net Operating Expense, Column (6)	$ 30,551
	(Page 6278)	
4	Reduction in interest, amortization and income taxes, Columns (7), (8) and (9)	$ 21,267
5.	Net reduction in Total Cost of Operations, Column (10)	$ 51,818
	(Page 6279)	

These reductions in cost were determined by the application of the principles used in projecting past operating costs of Colorado Interstate, as shown in Exhibit 76, to future operating costs as shown in Exhibit 136 (abstracted supra in Title 24).

The reduction in costs reflects the full net savings that result from the reduced use of those facilities that are un-

changed, and the reduced extent of the facilities that are curtailed. As to items of equipment, the construction of which is deferred, the corresponding notes issued on account of such equipment have been similarly deferred.

In the case of reduced pipe line diameter, bonds have been eliminated representing the saving in actual construction cost that could have been achieved with a smaller pipe. Different reduction in costs were made for years other than 1939 reflecting the costs normally to be expected in those years with reduced property required to be operated.

Statement 1 is reconciled with Exhibit 163 as follows:

"(a) Cost of operations of Canadian River Gas Company's property owned by it in 1939 per Exhibit No. 163	$2,184,086
"(b) Net deductions from such costs in 1939 made in this exhibit and summarized above	51,818
"(c) Annual cost of operations of Canadian River Gas Company in 1939 without Denver line direct sale gas shown by Column (10) of the attached Statement No. 1	$2,132,268"

The detail of Statement 1 showing the cost of operations for resale gas alone 1928 to 1947, inclusive, is shown below:

Calendar Year (1)	Gas Expenses (B) (2)	Other Expense (C) (3)	Total Expense (4)	Other Revenues (D) (5)	Net Operating Expenses (6)	Interest (7)	Amortization of Debt (8)	Federal Income Taxes (9)	Total Operating Costs (10)

Notes: (A) 7 Months.
(B) Details Attached—Statement No. 2.
(C) Details Attached—Statement No. 3.
(D) Details Attached—Statement No. 4.

On cross-examination Mr. Rhodes testified: (Vol. XLVI, p. 6285.)

Q. Mr. Rhodes, you use the same principle that you used in Exhibit 163?

A. Yes.

Q. And if I should ask you on cross examination regarding this exhibit questions of a similar nature involving the principal nature of the exhibit, your answer would have to be the same.

A. That is true.

* * * * *

Mr. Rhodes further testified: (Vol. XLVI, p. 6286.)

Q. Then if I should ask you similar questions regarding the same principle as to this exhibit as I did to Exhibit 136, your answers would be substantially the same?

A. Yes, they would.

* * * * *

Mr. Rhodes further testified: (Vol. XLVI, pp. 6288-6295.)

The Witness: This exhibit was based on the production of the amount of gas required exclusive of the direct sale gas which we assumed would not be supplied by Canadian River or go up the line.

By Mr. March:

Q. Did you assume, Mr. Rhodes, that there would be no other market for this direct sale gas if it was not used by the direct sale industrial customers on the Denver line?

A. Well, I made no specific assumptions except that I eliminated that volume of gas from the business of the Denver line and from the business of Canadian River Gas Company for the purpose of this study.

Q. Well, in order for you to reach the conclusions there would be a reduction in the volume of gas, therefore, a reduction in the volume of gasoline revenues, you had to assume, did you not, that the gas which was not used by the direct industrial load, the Denver line, would not be sold to anyone else?

A. In effect, yes.

Q. As a matter of fact, from a practical standpoint, in all probability that gas could be disposed of by Canadian

River Gas Company even if the direct industrial sale customers of the Denver line did not take the gas?

A. I don't know to whom.

Q. It would go to help supply the Chicago market, couldn't it?

A. That's already included in full.

Q. Yes, but, of course, if you had these direct sale industrial customers cut off the Denver line, why, you wouldn't have to increase your facilities to take care of the Chicago load, you could just divert that load over to the Chicago load immediately.

A. That's already been taken care of by Mr. Watson's testimony, that so many wells less would be required to produce the gas in the absence of that particular market.

Q. As a matter of fact it could very well be diverted, couldn't it, to the Chicago market?

A. No, the Chicago market is completely satisfied.

Q. What about the Milwaukee market?

A. The Milwaukee market is not attached.

Q. It will be attached shortly, won't it?

A. Well, whatever is going to Milwaukee is already provided for in the amount of gas to be produced in here.

Q. Yes, I know that. However, if you cut off the direct industrial customers off the Denver line then you won't have to increase your facilities to supply the Milwaukee load?

A. That's taken care of by Mr. Watson's testimony as to how much reduction in facilities would be possible. We have eliminated all of the facilities that Mr. Watson states could be eliminated if this business did not exist.

Mr. Spencer: "This business," meaning the direct sale Denver business?

The Witness: Direct sale business.

By Mr. March:

Q. Mr. Rhodes, would you as an engineer state here for the record that in your opinion if this gas was not delivered to direct industrial customers on the Denver line that there would be no market for the gas in the immediate future?

A. I don't know what would happen under such circumstances. I have confined this statement to an estimate of

what the operating cost would be to deliver the amounts of gas that the company is now delivering exclusive of that gas and with the reduced facilities, or the elimination of facilities, rather, that could be made with that reduced volume of gas.

Q. You wouldn't want to express an opinion in regard to that?

A. Well, it has nothing to do with this exhibit at all.

Q. You wouldn't want to express an opinion in regard to that?

A. I don't know what market there would be with regard to that particular gas if the Denver line wasn't taking it. That would be conjecture on my part.

Q. As a matter of fact, you have no intentions, do you, of cutting off the direct industrial load from the Denver line?

A. I haven't given any thought to it.

Q. As a matter of fact, this whole exhibit is purely a hypothetical conjecture as to what would happen if you did certain things?

A. No, that is an incorrect description of it. It is a determination of what the cost to Canadian River Gas Company would be in the absence of that business. The business is there, it is true.

Q. And do you expect the business to remain there?

A. Presumably.

Q. As a matter of fact, under the terms of the agreement under which—the basic agreements under which this project was inaugurated, it would be impossible to cut off that direct industrial sale gas?

A. I don't know.

Q. Under the terms of the contracts?

A. I don't know about that.

Q. You haven't made any study of those contracts?

A. Not from that standpoint.

Q. Then you wouldn't know?

A. I don't recall just what the basic agreement provided in that respect, but the facts are, I already put in an exhibit showing what it would cost with all of the gas, and here is what it would cost with a certain part of it missing.

Q. Although we are interested only in the Denver line here, you have included in this exhibit the production of gas by the Canadian River Gas Company for all purposes?

A. Well, in this exhibit I am interested in all of the gas the Canadian River produces except that which goes to the Denver line for sale direct to consumers.

Q. Now, I note here on Page 2 that you state: "The above reductions in cost were determined by the application of the principles used in projecting past operating costs of Colorado Interstate Gas Company shown by Exhibit No. 76 to future operating costs shown by Exhibit No. 136."

Now what do you mean by the principles?

A. Well, the basic principle is the principle of the added cost of added facilities or the increment cost principle, as it is sometimes referred.

Q. That's what you mean by those principles?

A. That's right. These adjustments here are made on what I call, and is frequently called, the increment cost basis rather than the average unit cost basis.

Q. I note here that you state that for 1939 the net reduction in the total cost of operations, Column 10, is $51,818. Now, would you, Mr. Rhodes, state that it would only cost in operating expenses $51,818 to take care of the direct industrial load on the Denver line?

A. That would be the added operating costs required to take care of the direct sale gas on the Denver line as an added volume of business.

Q. Yes. Of course, that's not the question I asked you—

Mr. Spencer: Read the question to Mr. Rhodes again.

(The question referred to was read by the reporter, as set forth above.)

The Witness: You might change that to read "Added total cost of operations," and you might further add it is the increment cost, as I previously described it, of producing and delivering that gas to Clayton Junction.

By Mr. March:

Q. Of course, I understand that this $51,818 is allegedly

the incremental cost, but my question was this, as to whether or not you would state for the record here that it would cost only $51,818 to take care of your direct industrial load on the Denver line, operating expenses—assuming that you did not have the other load?

A. No, I would not state that at all.

Q. You wouldn't even want to leave that impression in the record, would you?

A. Of course not.

Q. As a matter of fact, it would take almost as much to take care of the industrial load, if you only had that, as it would the resale load?

A. Other *thing* being the same.

Q. Well, why didn't you prepare an exhibit which would show that?

A. Because I hadn't been asked to, and I have given no thought to it as a situation worthy of consideration.

Q. Who asked you to prepare this exhibit?

A. Mr. Spencer.

Q. He outlined what kind of an exhibit he wanted and told you to prepare it?

A. No, he just told me he wanted to know what the cost of operations would be with the volumes of gas required other than direct sale gas and with the property that will be required to handle that curtailed business.

---

57. Sales Price of All Gas Sold to Colorado Interstate at Clayton Junction on Cost Basis Computed Under Contract.

The contract of January 3, 1928, between Colorado Interstate and Canadian (Exhibit 16) covering the purchase and sale of gas provides a method of determining the cost of gas in Article Tenth thereof.

In Exhibit 164, Witness Lusk (Vol. XLIII, p. 5998) shows the computed costs under basic contract terms of all gas delivered by Canadian at Clayton Junction, New Mexico, to Colorado Interstate, 1928 to 1947, inclusive. This exhibit shows the cost of operations of Canadian, 1928 to 1939, inclusive, and the estimated cost, 1940 to 1947, inclusive as related to the property owned and as required in the future.

up to the end of 1947, all as shown in Exhibit 163, abstracted supra. Such cost is divided between the well mouth production system, the gathering system and the transmission system, including the Bivins gasoline plant. Those parts of the respective system costs computed under basic contract terms are shown which constitute the cost of all gas delivered at Clayton, New Mexico, to Colorado Interstate. Mr. Lusk stated that these costs comprise (a) costs arising from operating and maintaining the property owned by the company, and (b) payments reimbursing the Colorado Interstate with interest for the funds advanced by it and used in the purchase and development of such properties, all under the basic method provided in the contract for the sale of gas to Colorado Interstate (Exhibit 16) at Clayton Junction. (Vol. XLIII, p. 5999.)

The costs were divided between the well mouth production system, the gathering system and the transmission system in order to compute the cost of all gas delivered at Clayton Junction. Most of the costs are directly charged to some one of the three systems. Those costs which are undistributed on the company's books have been divided as between the three systems pro rata with the directly charged expenses related thereto.

Payments in reimbursement of Colorado Interstate for moneys advanced for the purchase and development of the company's property comprise interest and amortization costs of the company's bonds and notes owned by Colorado Interstate, including interest on current advances. The aggregate total amount of bonds authorized and issued by Canadian was $11,000,000, the entire proceeds of which were used for the initial purchase and construction of Canadian's properties. Under the terms of the contract (Exhibit 16) subsequent purchase and construction of properties are financed through notes issued by Canadian to Colorado Interstate. These notes are designated straight notes, A notes, B notes and C notes, classification representing specific systems of property. (Vol. XLIII, p. 6016.) Maturities extend over a period not exceeding 120 months and for shorter periods subsequent to 1938 so that the last maturity is July 1, 1948. Such costs related to the bonds were divided as between systems pro rata with the book costs of the

property purchased or constructed by the use of the proceeds of the bonds. Such costs related to most of the notes have been charged directly to the systems developed through the use of (Vol. XLIII, p. 6000) the proceeds of such notes.

Interest on and amortization of notes issued to provide for general property have been assigned to the Denver pipe line properties in the proportion that general property was so assigned in Exhibits 67 and 133, relating to original cost of the Denver pipe line properties. The remainder was divided between the well mouth production system and the gathering system pro rata with the physical properties in those systems. Interest on current indebtedness was divided in proportion to the direct cost of operating and maintaining the three systems. The division of costs of operations as between systems is summarized by Statements 2 to 4, inclusive, with supporting Statements 5 to 8, inclusive

The contract of January 3, 1928, between the Canadian and Colorado Interstate makes provision for the division of costs as between separate deliveries of gas which make joint use of certain facilities. These provisions were based solely on the volumes of gas delivered, and ignored the other characteristics of the deliveries which affect their respective costs, and such provisions were used in assigning the cost of operations to the deliveries of all gas at Clayton. (Vol. XLIII. p. 6001.)

By way of example, the transmission costs are assigned to Clayton Junction deliveries in the proportion those deliveries bear to the total amount of gas delivered from Canadian River transmission line. The gathering costs are assigned to Clayton Junction deliveries in the proportion that the gas gathered to make such deliveries (including a pro rata share of gas used at Bivins) bears to the total gas gathered; and the well mouth production costs (including gas purchased) are assigned to Clayton Junction deliveries in the proportion that the gas produced to make such deliveries (including a pro rata share of gas used in gathering) bears to the total well mouth production.

The percentages of production, gathering and transmis-

sion costs chargeable under the contract for deliveries at Clayton are made on Statements 9 and 10.

Statements 1, 2, 3 and 4 show year by year from 1928 to 1947, inclusive, in summary form, the computed cost of gas under the basic contract terms of all gas delivered at Clayton Junction to Colorado Interstate. (Vol. XLIII, p. 6002.)

The quantities of gas are based on Exhibit 78, which shows the quantities up to and including 1939, and on Exhibit 80, which shows the estimate of future deliveries, from 1940 to 1947, inclusive. These exhibits are abstracted supra.

In arriving at total production costs all of the gas produced by Canadian for all of its various deliveries is included. All of this gas is involved in the gathering, except deliveries to the Amarillo Oil at the well mouth for delivery to Amarillo, Texas, free gas to the lessors, and gas used in the production system, and includes all the gas delivered at Fritch and at Bivins. (Vol. XLIII, p. 6004.) With respect to transmission, it includes the output at Bivins station less the gas that goes to Dalhart, Texline and Hartley, under the Amarillo Oil special contracts, and deliveries made to Clayton Gas Company. The difference is what is received at Clayton Junction by Colorado Interstate. The costs assigned to gas delivered at Clayton Junction found in production, are costs that are shared by all of the gas produced. It is only a portion of the total production costs which he took out and allocated to Clayton Junction delivery, contained in Statement 1 under the column "Production" that is divided strictly on an Mef. basis. (Vol. XLIII, p. 6005.)

The gathering costs, in the second column of Statement 1, are related to all of the gas which actually goes through the gathering system to Fritch or Bivins, and the figure in column 2 is the proportionate amount which he allocated to the quantity delivered by Canadian to Colorado Interstate at Clayton Junction.

The transmission operations include the compressor station costs at Bivins, and from Bivins to Clayton Junction.

The total costs of the transmission incurred by Canadian

were divided between the quantities delivered to Amarillo Oil, Clayton Gas Company, north of Bivins station, and deliveries at Clayton Junction to Colorado Interstate. (Vol. XLIII, p. 6006.)

The total output at Bivins in relation to the total Mcf. received at Clayton Junction is the factor used in determining the transmission costs.

In column 4 is shown the computed cost on all of these various factors. It includes all the gas received by the Colorado Interstate which it sells to industrial consumers as well as customers for resale. (Vol. XLIII, p. 6007.)

The percentage figure in column 12, Statement 2 of the exhibit, which a footnote shows is worked out on Statement 9, has been applied against the dollars shown in Column 11.

The figures used from 1940 to 1947 tie into Mr. Rhodes' Exhibit 163. (Vol. XLIII, p. 6008.)

The indirect expense is composed of all of the expenses shown on Statement 6, which is general and administrative expense and the Amarillo office expense.

He spread the indirect expense as between production, gathering, compressing and transmission system on the ratio of the direct gas expense. (Vol. XLIII, p. 6013.)

As shown on Statement 1, the computed cost of all gas under basic contract terms, delivered to the Colorado Interstate at Clayton Junction, 1928 to 1947, inclusive, is as follows:

Year	Production (B) (1)	Gathering (B) (2)	Transmission (B) (3)	Total (4)
1928 (A)	$ 133,948	$ 16,560	$ 50,017	$ 200,525
1929	528,703	99,648	181,232	809,583
1930	916,517	160,621	471,492	1,548,630

1946	625,352	120,927	486,372	1,232,651
1947	1,014,218	248,180	471,447	1,733,845

Notes: (A) 7 Months.

(B) Amounts in Columns (1), (2), and (3) from Statements 2, 3, and 4 respectively.

The operations of Canadian and its use of its production, gathering and transmission facilities involve sales to three individual customers, i.e., Colorado Interstate, Amarillo Oil Company and Clayton Gas Company. Deliveries to Colorado Interstate are made at two points: (1) Clayton Junction, New Mexico, for the Denver pipe line market, and (2) Gray, Oklahoma, for the Chicago pipe line market. Deliveries to Amarillo Oil are made at the well for the city of Amarillo and Channing markets, and at different points along Canadian's pipe line system for the Dalhart, Hartley and Texline, Texas, markets. Deliveries to Clayton Gas Company are made at the Clayton, New Mexico, town border. (Vol. I, pp. 65, 66.)

The contract under which deliveries are made to Colo-

rado Interstate at Clayton Junction, and the contract under which deliveries are made to Clayton Gas Company, are fully abstracted under Title 7 supra.

Under Title 8 supra there is abstracted the contract between Colorado Interstate and Natural Gas Pipe Line Company of America, dated October 15, 1931, together with amendments thereto, found in Exhibit 7-G, and as a part of the arrangement for the sale by Colorado Interstate to Natural Gas Pipe Line Company of America at Gray Junction, Oklahoma, a contract was entered into between Canadian and Colorado Interstate, dated June 1, 1938, and which is found in Exhibit 16. Section 6 provides:

> "The natural gas which Buyer requires for delivery to Natural Gas Pipe Line Company of America under the terms and provisions of the agreement between Buyer and said Natural Gas Pipe Line Company of America dated October 15, 1931 (abstracted under Title 8 in Colorado Interstate's brief), as modified from time to time, is a part of the gas sold and delivered under the terms of said 1928 agreement. Such gas shall be delivered by Seller to Buyer into the pipe line of Natural Gas Pipe Line Company of America at the junction between the pipe line owned by Texoma Natural Gas Company and Natural Gas Pipe Line Company of America near Gray, Beaver County, Oklahoma. Seller will continue in full force and effect the lease and operating agreement dated October 15, 1931, between Seller and Texoma Natural Gas Company, and the agreement of the same date between the same parties relating to the operation of the gasoline plant at Fritch, Texas, and will fully perform all the terms and provisions of each thereof in order to enable Seller to make delivery of gas to Buyer at Gray Junction, Oklahoma."

The contract between Canadian and Amarillo Oil providing for the sale of gas by the former to the latter at the well for the Amarillo and Channing markets, dated January 3, 1928, is Exhibit 16-B, which is contained in the contract of January 3, 1928, between Canadian and Colorado Interstate (the gas sales agreement) and which is Exhibit 16. The reason for the designation as Exhibit 16-B is that this contract was designated Exhibit B and made a part of

the gas sales contract just referred to. This contract is for a term of twenty years from the day on which Colorado Interstate begins delivering gas to Public Service Company of Colorado and "so long thereafter as Seller has available for delivery to Buyer hereunder quantities of natural gas which Buyer determines are profitable for it to buy under the terms of this contract." It provides in Article II that the gas to be sold shall be delivered by Seller and received by Buyer at the gate valves on Seller's wells, or the pipe connection points at which Seller receives natural gas bought for delivery hereunder from other producers. The price to be paid by Amarillo Oil is the "Seller's cost" as determined and defined in the contract.

Statement No. 7 and Statement No. 8 of Exhibit 164 are as follows:

Note: (A) 7 months

On cross-examination MR. LUSK testified: (Vol. XLV, pp. 6167-6168.)

Q. Mr. Lusk, you testified on direct examination last week with reference to the preparation of your Exhibit No. 164, did you not?

A. That is correct, yes, sir.

Q. And I notice the title of that, the exhibit, appearing on the cover of it was "Canadian River Gas Company Computed Costs under Basic Contract Terms, all gas delivered at Clayton Junction, New Mexico, to Colorado Interstate Gas Company, 1928 to 1947, inclusive."

Of course, the exhibit will speak for itself, but what was your purpose for the preparation of it?

A. To establish the cost of gas at Clayton Junction.

Q. Now, the computation of the figures of the cost set forth is limited, of course, in its scope to the provisions of the contract between the two companies as of January 3, 1928, I take it?

A. That is correct, yes, sir.

* * * * *

MR. LUSK further testified: (Vol. XLV, pp. 6183-6184.)

In Exhibit 164 where do you show the figures as set forth in the amortization cost of Statement 1, Mr. Rhodes' exhibit?

A. You can take any part of Mr. Rhodes' exhibit and add to it. The total debt amortization, Column 14—

Q. That is shown on Statement 7, Exhibit 164?

A. Yes. You take Mr. Rhodes' statement of total debt amortization and it is the same as my Statement 7, Column 14.

Q. Any statement of amortization of debt in Mr. Rhodes' exhibit would have to be made in your Statement 7?

A. That is right. If we were concerned in these exhibits in making small piecemeal changes, we would never finish in order to provide notes and amortization charges.

Q. But to that extent it doesn't include the true cost, even under the contract, does it?

A. I think it does. We reflect a true cost—as a matter of fact, I doubt if there is anything known as a true cost.

Q. What do you determine under true cost?

Note (A): 7 Months

A. I determine that this is not a true cost but a cost under contract.

Q. And the contract by its terms definitely puts that limitation as to what is to be included? That is what you stated?

A. That is right.

Q. Of course, the very theory of accounting is to record the correct cost?

A. The correct cost is recorded, not the true cost.

Q. What distinction do you want between true cost and correct cost?

A. I don't think any accountant, engineer or lawyer knows exactly what true cost is.

Q. A lawyer has to take that information from the accountant. What is the difference between your true and correct cost?

A. I don't know because I don't know what a true cost is.

Q. Then you don't know the difference between the two?

A. Well, I don't know the meaning of one, so I can't give you the difference between one and the other.

* * * * *

MR. LUSK further testified: (Vol. XLV, pp. 6190-6192.)

Q. Now let's go to Statement 2, Exhibit 164.

A. Yes.

Q. As I take it the items of rentals on operated leases—

A. Unoperated leases.

Q. Yes, unoperated leases. Column 3 is the same as that concerning which Mr. Rhodes testified, and he stated that he based his information there on that received from Mr. Watson as to what the rentals on unoperated leases would be projected into the future?

A. Yes.

Q. The other is as per book?

A. That is correct.

Q. Unadjusted?

A. Unadjusted.

Q. And I take it the same applies to Column 5, "Drilling Dry Holes." I notice in your exhibit the three items at the top of Column 5 that have the capital C affixed to them refer to what you call loss on sale of Cliffside property.

A. That is correct. In Exhibit 91 those three items for each of the years 1929, 1930 and 1931 are set out separately and I only put them in here to save a column.

Q. Why is this under "Drilling Dry Holes"?

A. Just as I explained, I put them in the classification with capital C for the purpose of saving an extra column.

Q. That is the only purpose?

A. Yes.

Q. Because otherwise they really wouldn't have a relation to it?

A. No, they would have no place in that column if it were related to strictly dry holes.

Q. You, of course, made no investigation of your own as to either the 1939 or subsequent figures, particularly as to the projections other than what Mr. Watson stated would be required?

A. With this exception: The amount shown in 1940, $49,100 is an actual expenditure for drilling the Amarillo No. 1.

Q. That is in 1940?

A. That is right.

Q. But the others are based on Mr. Watson's estimate alone?

A. They are Mr. Watson's estimates.

* * * * *

MR. LUSK further testified: (Vol. XLV, pp. 6206-6213.)

Q. Now, then, your "C" notes, in Column 4. In what way would any change in the drilling program affect them?

A. It wouldn't affect the "C" notes at all. The "C" notes are issued for general property like drilling and cleaning equipment—not drilling and cleaning equipment, general property in connection with Bivins camp, any general property in connection with the Masterson camp.

Q. Now, what are the mechanics? How does the company go about negotiating loans or borrowing of money under those two methods?

A. Which two methods?

Q. The "A" and "C" notes.

A. Oh, the "A" and "C" notes. Well, whenever the Canadian River Gas Company contemplates any building or the addition of any property, why, they just receive the money from the Colorado Interstate Gas Company.

Q. And issues what kind of a note?

A. Well, they issue a promissory note.

Q. Payable over what period of time?

A. Well, from 1928 up to 1938 it was 120 months. The

notes matured in 120 months. Now, subsequent to 1938, up until the time the contract expires between the Canadian River Gas Company and the Colorado Interstate Gas Company, those notes are issued with a flat maturity date of June 1, 1948 and if the note is issued in January of 1948, that note must be retired in six months.

Q. Well, they all have flat maturity dates of June 1, 1948?

A. From now on, yes, sir—from 1938 on.

Q. Well, are the notes payable on or before or are they absolute as to interest?

A. They are absolute.

Q. So if they don't—if the company doesn't continue to need that particular amount of money before the expiration of the maturity date of the note, they would still have to pay the note interest?

A. That is right.

Q. At the rate of six per cent per annum?

A. Yes.

Q. What is the necessary purpose of making the maturity date absolute?

A. The expiration date of the contract.

Q. If they wanted to make the maturity dates absolute, why didn't they make the interest portion of them on or before so that if they wanted to retire them before that time they wouldn't be obligated to continue the interest?

A. Well, the Canadian River itself, as the Canadian River, does not have any funds with which to retire any of the debt.

Q. Well, now, that's coming back to that assumption that you made a while ago that it is a non-profit company. Are you just applying that term to these operations as disclosed in your exhibit?

A. That's what this contract anticipates.

Q. Well, you broaden that, though, when you stated that it was a non-profit company—Canadian River.

A. No, I didn't.

Q. Didn't you make that statement?

A. I made that statement, yes, but I didn't broaden it or amplify it or expand it.

Q. Then I was correct in assuming that you stated it was a non-profit company?

A. I did.

Q. And you weren't limiting that statement just to this contract?

A. That's what the contract anticipates.

Q. Are these the only operations that are carried on under this contract—strike that.

The operations that are carried on under this contract by Canadian River Gas Company are the only operations of Canadian River Gas Company?

A. I think so.

Q. Well, then, if it is a non-profit company, how does it happen to have a surplus?

A. That is easily explainable.

Q. All right.

A. That surplus is due to the difference between the internal revenue bureau and the company in the methods of computing the depletion and depreciation.

Q. Is that the only reason that it does have a surplus?

A. The origin of that surplus, and that is the nature of that surplus.

Q. And has that been the history of it?

A. That is the history of that surplus.

Q. Then prior to that time it had no surplus?

A. In 1928 the Canadian River Gas Company and in 1929 the Canadian River Gas Company had a deficit.

Q. And subsequently, the only reason attributable to that surplus is this new method of calculation?

A. That's right. The Canadian River Gas Company I think I stated could have eliminated that surplus very readily and handily by staying away from the internal revenue bureau's dictates of how depletion and depreciation should be calculated. They didn't have to follow that, but for some unknown reason they elected to follow it.

Q. They had the option to do one or the other?

A. That's right, and at the present time the Canadian River Gas Company can reverse that surplus.

Q. They haven't in fact reversed it?

A. No, but they can.

Q. Are you certain that they can, Mr. Lusk?

A. Well, if Mr. Hendee or Mr. Shields or Mr. Dougherty told me to reverse that surplus I would reverse it in one fell swoop.

Mr. Dougherty: You are talking about reversing it on the corporate books; that would have no change on the income tax books, however?

The Witness: No.

Mr. Dougherty: You wouldn't make a reversal so far as the internal revenue is concerned?

The Witness: They don't care about it. They have collected their pound of flesh under their interpretation and they are out.

By Mr. Lange:

Q. Now, going back to those A and C notes, as I understand it, then both series of notes under the present plan, their maturities are fixed at June 1948?

A. That's correct.

Q. And they all bear a fixed rate of interest which would be applicable during the entire life of the note until their maturity date?

A. Oh, no.

Q. All right, in what way is that modified?

A. That's interest on a reducing balance all the time.

Q. Well, on the reducing balance?

A. Yes.

Q. If, however—wait a minute—what do you mean by "reducing balance"?

A. Well, if you gave me a series of notes for ten months—

Q. All right.

A. —and each bore and each note matured at the rate of $10 for each month, you wouldn't want to pay me interest on $100 when you paid off six notes.

Q. As I understand the way those notes are issued, the company has a certain drilling program at a certain particular time they determine that they may need $30,000 or $6,000 or whatever it would take to drill a certain number of wells and equip them, and once they determine that or whenever they determine that they issue a certain series of notes, don't they?

A. No, sir. I explained before that when the company launches on a well drilling program or a gathering line program or any other program for expansion, it all goes through an open account first. Then when that particular expansion is complete, the notes are issued.

Q. Well, during the time, though, they are carrying on those drilling operations and the funds are necessary to be

extended, until their program is completed they have that money on open account?

A. That's correct.

Q. And they are paying the same rate of interest on that money as they do on the notes, at six per cent per annum?

A. That's right.

Q. When they complete the certain drilling program, then as I understand it, at that time they execute this series of notes?

A. That is correct.

Q. And how are those notes payable, serially? In what manner?

A. Well, after 1938, as I explained before, there is a definite maturity date—June 1, 1948—and if a note is issued in 1943, for instance, for $100,000 for drilling, that note will mature in 1948.

Mr. Dougherty: Payable in instalments in the meantime?

The Witness: That's right.

Mr. Dougherty: You didn't make that clear, Mr. Lusk. What you do is take the remaining number of months from the date that the note is issued until June 1, 1948?

The Witness: I think I have explained that.

Mr. Dougherty: You haven't explained it to him in your oral testimony.

* * * * *

MR. LUSK further testified: (Vol. XLV, pp. 6222-6229.)

Q. Oh, I see. Going back on this same exhibit, Statement 7, to the notes, the straight notes under Column 2 applicable to new wells, we find the same situation obtaining there even in more pronounced fashion than that obtaining under Column 11 with reference to the amortization of the debt for compressor station units; isn't that true?

A. That would be true, but the mere fact that in 1947 the straight note amortization amounts to $290,802 doesn't mean that there are $290,802 amortized in an extremely short period. They are falling in those periods and as the time grows shorter and the program for expansion is being continued, then the latter years the rates will be that much higher as far as the amortization is concerned.

Q. All right, let's see what Mr. Watson has to say with reference to his drilling program in Exhibit 94. He proposes to drill a well in 1947. That's approximately $30,000. You, of course, have just one year to amortize that?

A. That's right.

Q. Suppose that there were a drilling of six wells in 1946 at his proposed or estimated figure of around $30,000. That would be $360,000.

A. $180,000.

Q. I beg your pardon, $180,000, and that would have to be amortized over a period of less than two years. Of course, I suppose it would be during that year?

A. That's right.

Q. And in 1945 he estimates the drilling of five wells. That would be $150,000?

A. Correct.

Q. And you would have about an average of two and a half or between two and a half and three years to amortize that.

A. That's correct.

Q. And in 1944 he has six wells. That would be $180,000?

A. Yes.

Q. And you have then three and a half to four years to amortize that?

A. That's correct.

Q. Isn't each of those, particularly as you get closer, an unusually short period to amortize investments of that character?

A. There is no question about it.

Q. And that is done in this instance solely and entirely because of the contract requirements?

A. That's correct.

Q. Then, of course, that drilling program, as I inquired of you before, is based on Mr. Watson's estimate, and any change in that would, of course, accordingly change this estimate as to amortization requirements?

A. That's right.

Q. Now, going back to the basic Statement 2 in the exhibit, the item of interest, that again refers and its basis is in Statement 8?

A. Statement 8, yes, sir.

Q. Now, then, just as an accounting matter, Mr. Lusk, ordinarily you wouldn't include interest as an operating cost or expense, would you?

A. No, not in regular accounting, we don't call interest charges part of an operating expense.

Q. So it is put in this exhibit or computed here purely because of the contract requirements?

A. That's correct.

Q. Now, what interest items are included in that column that are found *basicly* in Statement 8?

A. On the production system we have interest on the bonds, straight notes, A notes and C notes, and the current account.

Q. Now, as I take it, the interest items that appear there—well, first of all your production, under your production system is applicable to bonds through 1939, those are as per books, have been computed out?

A. No, the interest on the bonds can be taken right from the statement.

Q. What is the statement you mean?

A. The company's financial statement.

Q. Well, I mean, how do they get to this Statement No 8? Where is it taken from?

A. Well, I took the entire amount of bond interest paid in each year from 1928 to 1939 and separated between the three systems on the same basis that I separated the amortization of the bonds on Statement 7.

Q. And the interest, then, follows each accordingly?

A. Everything—7 and 8 then follow each other,

Q. And that portion of the projected interest from bonds, 1939, those are computed on the same basis following each projection as to the principal retirement?

A. Not on the bonds.

Q. Not on the bonds?

A. Not on the bonds. There is no change made in the bonds for any future program. It is all taken up through the notes.

Q. Well, now, let's see. I don't quite get this interest projection under bonds. For 1944 to 1947 the bonds remain statie during that time. Can you enlighten me on that?

A. Well, the bonds don't remain static. There is a portion of them retired every year.

Q. In what proportion are they retired during those last four years?

A. I am quite sure the indenture takes care of approximately $595,000 a year. Of course, that would reduce the interest during the last few years of 1944, 1945, 1946 and 1947.

Q. Now, do I understand this item of interest is entirely applicable to the bonds and several series of notes?

A. That is correct, yes sir.

Q. Now, how is that interest ordinarily paid; that is, in practice? In what interest do you make payment of the interest?

A. So far as the cash is concerned, there is no cash transaction between the Canadian River Gas Company and the Colorado Interstate Gas Company, as it is just a book entry.

Q. It is just a book entry?

A. Yes.

Q. When are those book entries made?

A. The interest is computed on the straight notes and all of the A notes and as the instalments fall due are on the instalment due, each month the interest is transferred from one company to another by means of a single book entry.

Q. Now, then, whenever the company determines to enter upon a construction program with reference, for instance, to the drilling of wells, and equipping them, say, having direct reference to Mr. Watson's program, for instance, how do they go about determining at what particular period of time or what part of the operation they want to issue a series of notes? He has a program projected over a period of some seven years which I suppose he would contemplate carrying out. At what stage of that program would you determine to issue a certain series of notes?

A. We wouldn't determine anything until the wells were finished.

Q. Under that there wouldn't be any notes issued until 1947?

A. If there wasn't any well-drilling program until 1947—

Q. But the program is beginning in 1941. They are going to drill a series—according to his projection—of wells every year.

A. That is right. Those five wells will be completed within that year.

Q. That is what I am getting at. When would they issue their first series of notes to take care of the drilling operation? Wouldn't it be limited to that year?

A. If there were five wells completed under Mr. Watson's program, there would be notes issued for the cost of those five wells.

Q. They would wait until the end of the calendar year 1941, for instance, and the money for the drilling operations would be on an open account basis?

A. No. For the five wells to be drilled in 1942 or 1941—

Q. Let's take 1941.

A. As soon as the well is completed there is a note issued for it.

The Trial Examiner: For the one well?

The Witness: For the one well.

While they are drilling the first well they are drilling the second well, the third well, the fourth well, and the fifth well, but those wells are not completed on the same day or same time. One might be completed in February, another in March, another in April and another in May. As soon as those wells are completed the amount expended for those wells which appears in open account is then closed out of open account and thrown into notes.

---

58. Sales Price of All Gas Sold to Colorado Interstate at Clayton Junction, Except Its Direct Sale Gas, on Cost Basis Computed Under Contract.

In Exhibit 167, Witness Lusk shows computed costs of Canadian under basic contract terms of resale gas delivered at Clayton Junction to Colorado Interstate, 1928 to 1947, inclusive.

He explained (Vol. XLVI, pp. 6345, et seq.) that in Exhibit 164 the computed cost under basic contract terms of all gas delivered at Clayton Junction to Colorado Interstate was shown, and that this exhibit shows the annual cost of resale gas only; otherwise, it is identical with Exhibit 164.

He took Exhibit 165, Witness Rhodes, and separated that exhibit between production, gathering, transmission and compressing systems. His figures represent the cost of reduced operations, and include change in the size of the pipe line from Bivins Station to Clayton Junction, from the 22" pipe line to a 20" line, and the reduced facilities in the field and in the gathering system due to the reduced quantities of gas (p. 6346).

The computed cost under basic contract terms, of resale gas delivered at Clayton Junction to Colorado Interstate, 1928 to 1947, inclusive, shown in Statement 1 of Exhibit 167, is as follows:

Year	Production (B) (1)	Gathering (B) (2)	Transmission (B) (3)	Total (4)
1928(A)	$ 58,443	$ 14,425	$ 62,224	$ 135,092
1929	289,616	95,091	259,202	643,909
1930	646,133	156,831	464,746	1,267,710
1931	805,787	116,457	446,370	1,368,614
1932	738,179	97,793	447,600	1,283,572
1933	618,066	88,856	424,984	1,131,906
1934	452,911	64,254	421,666	938,831
1935	419,484	56,160	373,431	849,075
1936	401,147	62,574	402,180	865,901
1937	430,365	70,080	406,003	906,448
1938	431,795	74,469	424,728	930,992
1939	435,047	74,732	445,095	954,874
1940	448,837	79,683	524,606	1,053,126
1941	431,753	86,236	498,882	1,016,871
1942	389,910	79,645	490,305	959,860
1943	377,127	77,883	545,324	1,000,334
1944	369,123	75,356	557,147	1,001,626
1945	363,761	74,608	538,442	976,811
1946	411,150	86,344	523,319	1,020,813
1947	806,314	241,083	508,518	1,555,915

Notes: (A) 7 Months.

(B) Amounts in Columns (1), (2), and (3) from Statements Nos. 2, 3, and 4, respectively.

On cross-examination Mr. Lusk testified: (Vol. XLVI, pp. 6344-6351.)

Q. Mr. Lusk, the use of the phraseology "resale gas delivered at Clayton Junction," I assume refers to the gas or that part of the gas actually delivered at Clayton Junction which is taken by Colorado Interstate Gas Company and then resold to public utility customers in the State of Colorado?

A. For resale, that's correct.

Q. And also the Colorado-Wyoming Gas Company?

A. That's right.

Q. In other words, there has been taken out the quantities which Colorado Interstate Gas Company sells directly to industrial consumers which consumed that gas?

A. That's correct.

Q. I think you might read into the record this one-page preliminary statement first.

A. "Exhibit No. 164 in this proceeding shows year by year Canadian River Gas Company's computed cost under basic contract terms of all gas delivered at Clayton Junction, New Mexico to Colorado Interstate Gas Company under the contract between Canadian River and Colorado Interstate of January 3, 1928 which is Exhibit No. 16 in this case. Had the gas delivered to Colorado Interstate Gas Company at Clayton been limited to its requirements of resale gas, then lower total annual costs of the gas would have resulted. This exhibit with its attached statements shows such annual costs of resale gas otherwise identical with Exhibit No. 164 in this proceeding dealing with all gas.

"It is shown by Column (4) of Statement No. 1 that in 1939 the contract cost of resale gas delivered at Clayton Junction, New Mexico to Colorado Interstate Gas Company amounted to $954,874 and that it had fallen from a maximum of $1,368,614 in 1931. These figures show a saving in 1939 of $266,134 below the corresponding cost of all gas referred to above."

Q. In what way is this Exhibit 167 related to Mr. Rhodes' recent exhibit 165 which is entitled "Cost of Operation of Canadian River Gas Company for Resale Gas"?

A. Well, I have taken in this exhibit Mr. Rhodes' Exhibit 165 and using all of the data contained in this exhibit

and all of his computations and separated Mr. Rhodes' exhibit between the production, gathering and the transmission and compressing system.

Q. Do your figures, therefore, represent the cost on reduced operations and does that include such change in the size of the pipe line from the Bivins station to Clayton as computed by Mr. Rhodes previously?

A. That is correct.

Q. That is on the basis, I think, of what he termed the 20-inch line?

A. That is correct.

Q. It involves that change in the physical facilities of transmission?

A. It involves the changes of reducing the size of the 22-inch to 20-inch from Bivins to Clayton and involves the reduced facilities in the field and in the gathering system and whatever changes are made due to the reduced size of the line and the reduced quantities of gas in the compressing stations.

Q. I note in your Exhibit 167, Mr. Lusk, Statement 2, under Column 5, that there is apparently that same typographical error with a capital C after the figure $61,095 which we found in Exhibit 164?

A. That's correct. In my copy I have eliminated that and made a note when I came to the exhibit, or came to this statement, I was going to make that same reference that you are making now.

Mr. Dougherty: If the Examiner please, may the reporter be directed to eliminate that capital C where indicated?

The Trial Examiner: Yes, we'll have the reporter do that.

By Mr. Dougherty:

Q. Are there any other typographical errors in this exhibit?

A. I don't know of any at the present time.

Q. Is the general form of Exhibit 167—by that I mean the form of the statements and the subject matter, similar to 164?

A. Yes, sir.

Q. So that if you took Exhibit 164, Statement 1, that it is similar to Statement 1 in Exhibit 167?

A. That's correct.

Q. And the difference between the totals on Statemen No. 1 in Exhibit 164 and those on Statement No. 1 in Exhibit 167 would represent the amounts that have been estimated as being savings or amount that would not have to have been expended if the lesser quantity of gas had been sold at Clayton?

A. In Statement 1 of Exhibit 167 is purely resale gas, and Statement 1 of Exhibit 164 is all gas, and the difference between the two represents the difference of direct sale gas.

Q. Now, are these subsequent statements in Exhibit 167—or do the subsequent statements in Exhibit 167 deal with the same character of costs as the statements in Exhibit 164 which bear the same numbers?

A. Yes, sir.

Q. So that by taking Statement No. 2 or any other number in the two exhibits the comparison can be made of the different amounts which have been estimated in both exhibits?

A. The statements in Exhibit 167 and the statements in 164, ten in number in each case, correspond with each other. One is resale gas and the other is all gas.

Q. In general, then, that is the difference in dollars that are shown, and I take it that the total dollars in Exhibit 164 are greater in most, if not all, instances than in 167—

A. That's right.

Q. And that represents what might be called the incremental cost as computed which the company incurred—the Canadian River Gas Company incurs in providing this additional quantity of gas which it actually does sell to Colorado Interstate at Clayton; that is, the quantity which is then resold by Colorado Interstate to direct industrial customers?

A. They are both taken from Mr. Rhodes' Exhibit 163 and 165, and as Mr. Rhodes terms it, it is the incremental cost of the gas delivered at Clayton for direct sale purposes, the difference between the two statements.

Q. The basis of the statements is incremental cost rather than some allocation on a volume basis?

A. That's correct.

Mr. Dougherty: I think that is all the direct I have, if the Examiner please, because it is substantially the same as Exhibit 164, and I think that brings that out.

The Trial Examiner: Very well, Mr. Dougherty.

Cross Examination.

By Mr. Lange:

Q. Mr. Lusk, in connection with your cross examination on Exhibit 164, I think it was very definitely fixed—or the facts were very definitely fixed, that this study in 164 as a cost was definitely limited as per contract of January 3rd, 1928.

A. That's right. It is based on the contract, that's right.

Q. And reflects your study of costs of gas within the limitations of that contract?

A. That is correct.

Q. Now, then, I take it in this Exhibit 167 wherever you speak of costs or wherever you make a comparison with a reduction as you set forth in the written statement accompanying this Exhibit 167, particularly the last sentence, that that means a reduction also within the limitations of the contract, to start off with?

A. I thing that's right, yes.

Q. And then applied to resale gas alone?

A. That's correct.

Q. So this study in 167, first of all, is confined to the limitations of the provisions of the contract of January 3rd, 1928, as to all of which applies to all gas, and then on the additional assumption that only resale gas is involved?

A. I think you mentioned the wrong exhibit. Did you say 167? Did you say 167 was resale gas? That's 164.

Q. 167 applies to resale gas and 164 to all gas.

A. That is correct.

Q. Otherwise, those assumptions are correct as stated?

A. That's right.

* * * * *

Mr. Lusk further testified on cross-examination: (Vol. XLVI, p. 6358.)

Q. Now, then, throughout this whole exhibit, of course, you have necessarily the additional assumption that you

did not have in your Exhibit 164 with respect to estimating costs, because in Exhibit 164 you took account of all of the gas under the contract and in Exhibit 167 you are confining it to the contract on the additional assumption that it is just resale gas?

A. That is correct.

Q. So I will ask you whether all of the principles that you discussed in 164 as applicable there, you also adopt as applicable to the computations in Exhibit 167?

A. Yes, sir.

* * * * *

MR. LUSK further testified on cross-examination: (Vol. XLVI, pp. 6362-6365.)

Q. Now, then, with reference to Column 8, Amortization of Debt, according to your Exhibit 164, Statement 2, in what respect do the figures in Column 8 of Exhibit 167 differ from the figures of Column 8, Exhibit 164?

A. There are slight differences that crept in on these exhibits. One is in the calculation of the amortization of debt in the production system with the resale gas—with the direct sale gas eliminated and with certain of the properties eliminated due to the resale gas program. The proportion of the bond applicable to the production system was raised slightly because the overall property base was reduced and the production system percentage of the property was not reduced in proportion. It was a change in the overall base. That made these calculations for resale gas slightly higher in some years.

Q. In arriving at the figure in Column 8, Exhibit 167, you necessarily had to depart from the method of calculations as set forth in the contract in determining amortization, didn't you?

A. No, sir.

Q. You don't?

A. No. We take the amount of amortization as set forth in the contract and apply the difference due to the reduction in property. The principle followed is the same.

Q. And in determining the amounts to be set forth for amortization of debt under this column, under this proposed estimate, or, rather, under this estimate limiting itself to resale gas only, you of course do not take into consideration and do not in any manner predicate these figures on

what the actual reserves of gas are for the Canadian River Gas Company?

A. None whatever. The application of any reserves for Canadian River Gas Company does not enter into this statement at all.

Q. In other words, in that calculation the same method applies as applied to the calculations on debt amortization in Column 8, Statement 2, Exhibit 164?

A. Yes, sir.

Q. Now, then, under Column 10, Federal Income Taxes, I notice that the year 1947, in it you have a sizable increase in the tax. How did you get that? How do you account for that?

A. That is the same as the increase in Statement 2 of Exhibit 164. It is due to the elmination of the Chicago load and the consequent reduction in depletion—not depletion, but the constant reduction in the severence taxes and all other forms of taxes incident to the Chicago gas line.

Q. Now going back from 1947 to 1944, in 1944, Exhibit 164, Statement 2, Column 8, you have a minus under your income tax figures showing a loss. You have considerable profit in this statement in Exhibit 167, haven't you?

A. Why, in Exhibit 167 the income tax for 1944 has been computed at $18,460. That is due to the amortization of debt in relation to the depletion and depreciation as taken.

Q. What I am trying to reconcile is that the lowest figure on the total and the profit figure indicated this $18,460.

A. That is different. Under the resale program the difference between the amortization of debt and allowance for depreciation and depletion as allowed by the Bureau of Internal Revenue would be much different than under the all gas program.

Q. That accounts for the difference?

A. Yes, sir.

Q. And under this resale plan you would have a profit indicated by the income tax payments, whereas the loss is indicated under the total statement?

A. That is really not a loss. That is a minus shown to tie you in—the Federal income tax ties into the three systems. It is shown as a minus to the production system in order to tie it all in.

Q. I take it that the calculations that you have made and

resulting in the future set forth in this exhibit in the several statements were made in a similar fashion as those were made in Exhibit No. 164 and as to each statement?

A. Yes, sir.

* * * * * *

MR. LUSK further testified on cross-examination: (Vol. XLVI, pp. 6369-6371.)

Q. I take it that these calculations that appear in Statement 9 of Exhibit 167 were reached on the same basis of the calculations on Statement 9, Exhibit 164?

A. Yes, sir, the same principle was followed throughout both exhibits.

Q. Of course, Mr. Lusk, the company is not in fact operating on the basis as indicated in this cost exhibit. They are not so segregating the items on their books are they?

A. They are segregated into certain proportions of the operating expenses divided between the systems; they segregate taxes by systems; they segregate bonds between two systems; they segregate notes and other evidences of debt between the two systems.

Q. The company is not in fact presently limiting its sale to resale customers?

A. The Canadian River Gas Company?

Q. Yes.

A. The Canadian River Gas Company doesn't make any distinction between resale customers and direct sale customers.

Q. And it doesn't make any sales at all to direct industrials?

A. Not Canadian River Gas Company, no.

Q. It makes all of its sales to—let's see. It is the Colorado Interstate Gas Company; the Amarillo Oil Company—

A. Yes.

Q. And who are the others?

A. Well, the Amarillo Oil Company is divided into several contracts and the Colorado Interstate, and the Clayton Gas Company.

Q. That is right.

A. The Canadian River Gas Company wholesales gas.

Q. Their contracts are in evidence in this proceeding. The main one, of course, we are concerned with is the contract in Exhibit 16.

A. Yes, sir.

Q. Under the terms of which, particularly Paragraph or Section 10, you have arrived at these cost figures that appear in Exhibit 164 and you have related them to resale only in Exhibit 167?

A. That is correct.

Q. But in so far as the Canadian River Gas Company is concerned, it doesn't now nor has it in the past endeavored to limit its sales to resale gas only, has it?

A. No, sir, there is no distinction of gas sales in the Canadian River Gas Company and has not been any since the company commenced operation.

Q. Nor is there any contemplated as far as you know?

A. As far as I know, no.

---

59. Estimates of Natural Gas Reserves.

Testimony of A. A. HAMMER, Federal Power Commission Engineer, who testified for and on behalf of the Commission.

Mr. Hammer submitted exhibits and other testimony with respect to the original and remaining reserves of natural gas in the Texas Panhandle Field and the reserves pertaining to the acreage owned by Canadian River Gas Company. Mr. Hammer utilized the pressure decline method in computing such reserves. His testimony, Vol. 51, pp. 7049-7123, is as follows:

My name is A. A. Hammer, residence, Washington, D. C., and I am presently employed by The Federal Power Commission as Engineer, and have been so employed since January 3, 1939. I have spent approximately one and one-half years in connection with the present proceedings, which time was consumed primarily with an examination of all the records and the files of the oil and gas division of the Texas Railway Commission at Pampa, Texas, and at Austin, Texas, together with an accumulation of a large volume of sheets and records totaling more than 30,000 photostatic records pertaining to the Texas Panhandle gas field, and in addition, an estimated 10,000 additional sheets that were taken off manually pertaining to the same field. My experience as an Engineer is as follows (Vol. 51, pp. 7049-7053):

A. I am a graduate of Washington State College, the class of 1907. I majored in geology and mining. I took minor work in chemistry and general engineering and from 1907

to 1912 I was employed as a chemist for the Washington Portland Cement Company in the western part of the state of Washington and also a geologist for the State of Washington, working on a survey of cement materials in the state.

In 1912 I went into South America for the Barber Petroleum Company—that is a subsidiary of the Caribbean Asphalt Company—as geologist and engineer doing work in Venezuela and Colombia. I returned to the United States in the fall of 1914. During the latter part of 1915 and the early part of 1916 I did work in the Province of Alberta, Canada, investigating oil and gas problems.

In August 1916 I was appointed to the petroleum division of the United States Bureau of Mines in connection with the development of oil and gas on Indian lands in the state of Oklahoma. This work included the actual supervision of the drilling and completion of oil and gas wells, the conservation of oil and gas, the handling and control of high pressure gas wells, and all allied subjects.

The work in Oklahoma continued until 1919 during which time I did special work for the War Trade Board on oil and gas well equipment in use or in warehouses in Oklahoma and Kansas. I also did special work in connection with the Council of National Defense on surveys of refineries as to production available for the prosecution of the war; also during that period special work was done for the Internal Revenue Bureau in the valuation of oil and gas properties.

In 1919 I was transferred to the state of Texas and opened up the first office for the United States Bureau of Mines—I mean the petroleum division—in that state, and I was in sole charge of that work. It was during the time of the oil boom at Ranger and Burkburnett, Texas, and during that work I assisted the Chairman of the Texas Railway Commission, Mr. Terrell, in the preparation of the first conservation regulations of the state.

In 1920 I resigned from the Bureau of Mines and spent one year with the Sinclair Oil Company as an assistant to the general superintendent on special production problems. In 1921 I went to New York City where I was employed by the then Union Oil Company of Delaware in attempting to reorganize the engineering and geological work.

In April 1941 I was offered—

Q. April 1941?

A. April 1921.

In April 1921 I was offered a position and accepted a job as chief of the geological and engineering staff of the Absaroka Oil Development Company, a subsidiary of the Northern Pacific Railway Company. The company was organized to develop the land grants of that railway company.

In the autumn of 1925 I made my first trip into the Texas Panhandle. About a month was spent there looking over the possibilities in various localities lying adjacent to the present producing areas. I might say in that connection that the Hammond Cattle Company tried to interest us in a ranch that they had in Roberts County lying to the northwest, and having spent a month down there I decided that there was neither oil or gas in Roberts County so I turned the proposition down. That was my first visit into the Texas Panhandle.

Q. Roberts County, Texas?

A. Roberts County, Texas.

Between 1926 and 1930 a period was spent in charge of the geological and development program for the Hurley Oil Company of Tulsa, Oklahoma in West Texas. During this time I became thoroughly acquainted with the geological and drilling problems in West Texas as most of the oil and gas in that general territory is produced from limestone and dolomitic limestone. I acquired more than a passing knowledge of both the reservoir rocks as well as drilling and producing problems.

Between 1930 and 1933 some time was spent in the Rocky Mountain states associated with the Minnesota Northern Power Company, now the Montana-Dakota Utilities Company. This work consisted of the estimation of gas reserves in the state of Montana and the development of gas fields; the examination of new areas, and new markets; these investigations were carried on in Montana, Colorado, Utah, and in the state of Washington.

Between 1932 and 1939 time was spent largely on gas problems in Utah, Colorado and New Mexico, largely in

connection with the development and utilization of the carbon dioxide gases from those states.

Since January 3, 1939 I have been employed by the Federal Power Commission.

Q. As an engineer?
A. As an engineer.

Mr. Spencer: Mr. Examiner, I assume that counsel for the Commission expects to submit here such an exhibit having to do with gas reserves of the Texas Panhandle through this witness.

Mr. March: We have already given you copies of it.

Mr. Lange: Yes.

Mr. Hammer then read into the record the following prepared statement (Vol. 51, pp. 7056 to 7071):

A. This is entitled: "General Statements of the Problem Concerning the Estimate of Gas Reserves in the Texas Panhandle Field."

"Since the early life of the Texas Panhandle field, many and variable estimates of the gas reserves have been given and in one form or another have been called to the attention of those interested in the natural gas business.

"These estimates have naturally varied from time to time, progressively in years, approaching more nearly a true figure when made by unbiased geologist and engineers, as the amount of development widened over the field and the necessary factual data became more wide spread and dependable.

"In recent years, however, there has been too large a variation in reported estimates, when considered in the light of data now available.

"In order, therefore, to arrive at the best possible estimate of reserves, it became necessary to make an exhaustive research to initiate and carry through a thorough study of all the available data having a bearing on the problem.

"Collection of Basic Data

"The collection of basic data on which to make a study of the gas reserve of the Texas Panhandle Gas Field required the entire time between June 15, 1939 and November 8, 1939.

"During this time five employes of the Federal Power Commission were actively engaged in securing records of essential data having a direct bearing on the subject. By far the larger part of the data were secured from the Railroad Commission of Texas, from official records in the offices of that Commission at Pampa and Austin, Texas.

"In addition to the records of the Railroad Commission, data were secured from a number of the larger companies producing and transporting gas in the Panhandle field.

"More than 30,000 sheets of records were taken by photostatic processes. In addition, the equivalent of an estimated 10,000 sheets were taken by manual copying.

"These records covered all the data on gas withdrawals, and pressure of gas wells, in the files of the Railroad Commission from the time of the first reports up to August 1939.

"They also included the records of all the logs of gas and oil wells which it was possible to secure. By a close estimate, the log record of all wells drilled was found to be complete to the point where less than 100 were missing or unobtainable.

"Other data taken included:

"(a) A large number of Bureau of Mines back pressure curves for the determination of open flow of gas wells were secured both from the Railroad Commission, as well as from a number of the larger gas companies, including those of the Canadian River Gas Company wells.

"(b) Records of the acidization of gas wells were secured from the companies engaged in that work, showing the name and location of the wells, the amount of acid used in treatment, and the increase or decrease in open flow after treatment.

"(c) Reproduction of the records of many hearings before

the Texas Railroad Commission dealing with the problems affecting oil and gas production, wastage of gas, and allied subjects were taken.

"Besides the collection of recorded data, many trips were made through the field, during the summer of 1939, to observe field conditions and to discuss the various problems with field superintendents, engineers and geologists employed by both major and smaller companies engaged in the production of natural gas and oil.

"Much valuable information was secured from these men on questions having a direct bearing on field conditions that affect the question of available gas supply in the field.

"It required the entire working time of six men for a period of eight months to tabulate and allocate the mass of data into a form suitable for a study of the gas reserves in the field.

"Maps and Well Locations

"County maps were secured of each of the counties in which any part of the Panhandle field occurs. These maps are of Wheeler, Gray, Carson, Hutchinson, Moore, Potter and Hartley counties Texas. No maps were secured of Collingsworth or Oldham counties, because of the extremely small portion of those counties lying in either proven or possible gas territory.

"These maps had been brought up to date as to well locations. However, to be sure of the locations, the maps were checked against the locations given on the well logs. The maps were then checked against field maps of various companies as a further check on locations of wells.

"We are, therefore, more than reasonably sure that the well locations on the maps used in the determination of weighted areal pressures are correct.

"Discussion of Detail Problems on the Estimation of Gas Reserves.

"The problem confronting anyone who undertakes of the estimation of gas reserves in the Texas Panhandle field is unusual when compared to the ordinary gas field. Among

the reasons for this statement is the large areal extent of the field, which has not been definitely delimited to date, the occurrence of gas in a dolomitic limestone reservoir over such a wide area, and the inherent variables in reservoir characteristics that are universally found in such reservoirs.

"Without going into the question of the agencies causing porosity in dolomites or dolomitic limestones, all competent geologists and petroleum engineers recognize the fact that there is almost universal variation in voids or pore space throughout any given segment of such formations. The changes in porosity may vary widely from the tiniest void, originally existing, to cavernous conditions.

"What size the voids are is indeterminate because the shape and size of such voids are dependent largely upon the action of solvents existing either in the gas, water vapors or circulating underground waters in past geologic times. In fact, there is ample evidence to indicate solution in one place and redeposition in another in the same general producing formation, as shown by both calcite and anhydrite deposited in limestone or dolomites where small fissures originally existed.

"Furthermore, it is entirely possible that the limestones and dolomites that act as a reservoir for gas in the Panhandle field may have been at one time at, or close, to the surface of the seas in which they were deposited, and hence, in the zone of influence of oxidation, areal, or subareal erosion.

"It is a recognized fact that where competent sediments or strata (component in a geologic sense meaning fragile, not subject to bending or flowage without fracture), such as the reservoir rocks of the Texas Panhandle gas field, have been subjected to stresses that result in major folding and faulting, fracturing of the competent beds occur, resulting in voids between the faces of the fractured material.

"This is more particularly true where the folding is accompanied by major faulting. Where such conditions exist, there is always more or less fracturing, often in the form of parallel faulting extending away from the zone of

major displacement until the point of minimum stress has been reached.

"Under such conditions, where competent beds exist, there occur an indetermine number and size of fractures which make the determination of the percentage of voids or pore space impossible to determine.

"This is particularly true in the Panhandle field in the area where the Canadian River Gas Company acreage is located. This area is delimited on the south side by a fault estimated as having a displacement of from 400 to 800 feet, and is situated principally at the highest structural part of the entire field where the greatest stresses were probably exerted at the time folding took place.

"In a more specific and definite way, Mr. H. F. Stevens, Commission engineer, and I examined numerous cores of the gas producing formation taken during the earlier development of the field, and in no case had it been possible to secure a core through that part of the producing horizon from which the major flows of oil or gas come. Only that part of the core from which little or no gas or oil could be recovered. Determination of porosity from these recoverable portions of the cores would, in no wise, give an indication of the porosity at points of maximum production of oil or gas.

"Since the practice has become almost universal to complete wells with cable tools (percussion tools), there is absolutely no way to determine the porosity of the original producing formation in place in the ground (undisturbed before drilling) from an examination of the crushed sample taken at the well head.

"To anyone realizing these conditions existing in the Panhandle field, it has been realized at all times a futile effort to attempt to determine the porosity of the reservoir beds, in the Panhandle field, as a means for the determination of reserves by the porosity-pressure method.

"Hence, the only method worthy of consideration is the determination of reserves by application of the principles of Boyle's law. That is the determination of the decline in pressure due to the removal of known volumes of gas at a constant temperature.

"During the life history of any large gas field, even such procedure is of minimum value until such time as sufficient development has occurred as to establish a widespread index of data uniformity distributed over the field.

"When that time has been reached, then the production-pressure decline method offers the most reliable method for the determination of gas reserves where conditions are such as those found in the Texas Panhandle field.

"Furthermore, conditions as to subnormal pressure in the Panhandle field more nearly approach the ideal for the application of Boyle's law. That law presupposes a container of constant volume and temperature unaffected by any extraneous pressure, and where at the start the gas is under a constant pressure.

"Since there is no noticeable tendency of water encroachment around the edges of the field, and hence, little or no extraneous pressure being exerted on the gas reservoir, the field closely approaches an ideal condition for the application of Boyle's law in the determination of the gas reserves in the field.

"Five-Year Period Instead of Total Data

"After having analyzed and studied all the available data previously collected, it was found advisable and necessary to utilize only that segment of life history of the field during which it had reached its greatest period of development and during that period when records and factual data were such that a large degree of dependence could be placed in them.

"It was evident that such a period existed only after the Railroad Commission of the State of Texas, moving under a conservation act passed by the state legislature, obtained a large degree of effective enforcement during the year of 1935.

"Prior to 1935, the history of the field is, in modern terms, a 'black-out' of confusion, and little dependence can be placed on recorded data or estimates of wastage of gas.

"Pressures were never uniformly taken, and those taken and recorded meant little because they were usually taken

with steam gauges probably seldom calibrated against either a master gauge or dead-weight tester.

"No uniform pressure base on which to report gas withdrawals existed. Gas was reported on a wide range of pressure bases, no record of which is available in the offices of the Railroad Commission of Texas or elsewhere as far as can be ascertained.

"Since August 1, 1935, the engineers of the Texas Railroad Commission have kept records of such character that they may be readily used as a basis upon which to calculate the gas reserves of the Panhandle field.

"It was, therefore, determined to base the calculation of gas reserves upon the data of record between August 1, 1935 and August 1, 1939.

"Detailed Discussion of Geology Not Necessary.

"Any extensive discussion of the historical or structural geology of the Texas Panhandle gas field is neither necessary or advisable in arriving at an estimate of the gas reserves of that field.

"These features have become so well known that any such discussion would only add material to the record of no essential value.

"It does seem pertinent, however, to state that the producing horizons of the Panhandle gas field are of the same geologic age as those producing gas in the Hugoton gas field.

"These formations are of the lower Permian age. In the Panhandle field they are referred to as the 'Big lime' divided into the brown dolomite, the white dolomite, and a zone consisting of arcosic material, dolomite and limestone. The latter may be of Pennsylvanian age. This point is not certain.

"In the state of Kansas, geologists have assigned the following names to rocks of the same geologic age; named in descending order, they are as follows:

"The Harrington dolomite,
"The Krider dolomite, and
"The Winfield dolomite.

"All are assigned to basal Permian or of Wichata-Albany age as described for central Texas.

"Water Conditions

"There is very little or no effective water movement in a true sense of edge-water encroachment.

"During the summer of 1939, Mr. H. F. Stevens and I inquired on many occasions of geologists, field superintendents and others, and found no one who had any idea that water encroachment from the edge of the field was serious, or even noticeable. Neither did we see any evidence of excessive water being produced from oil wells. What danger there is in the field from water encroachment is brought about by improper completion of wells and inadequate repair work to shut out bottom water. These cases are few in number, so that actually there is no serious water trouble in the field.

"General Statement of Method Used

"The method employed for determining gas reserves by the construction of isobaric maps, the determination of weighted average pressures therefrom, and the utilization of accumulated production against the weighted pressures naturally assumes the following conditions:

"1. That development or drilling has been sufficiently wide-spread to give an index of characteristics of the field;

"2. That there has been a sufficiently long history of production to the point where wide-spread indexes have been established as to the volumes removed and the resulting pressure decline;

"3. When such a life history has been established, then the field, or any part thereof will continue to follow the same characteristics throughout the future life thereof, as has been established in the past, unless seriously affected by mechanical condition of the wells.

"The method used in the determination for the gas re-

serves under Canadian River Gas Company lands is the same as that used for the determination of the reserves for the entire field.

"This method is based on Boyle's law, which states that the volume of any given weight of gas at constant temperature varies inversely as the pressure. Briefly the steps taken to arrive at a determination of reserves are as follows:

"1. The construction of isobaric maps for a period of five years, on 10-pound intervals, from 1935 to 1939, on county maps of a scale of 4,000 feet per inch;

"2. The division of the maps into areas or quadrants;"

That term "quadrant" there I might explain. We had to have some term applicable to the areas so we simply chose that name. It hasn't any particular significance except that it refers to areas.

"3. Determination of quadrant areas and isobar areas by use of planimeter;

"4. Calculation of weighted average pressures for each year for each quadrant;

"5. Compilation of production for each quadrant yearly for the five-year period, accumulatively;

"6. Balancing these previously obtained values for each quadrant with like values of immediately adjacent quadrants where the configuration of isobars indicate possible effective movement of gas either to or from the quadrant in question;

"7. The determination of production per-acre-pound decline on the entire effective area;

"8. Utilizing this production per-acre-pound factor in arriving at the reserves for the quadrant in question by applying it to the weighted average pressure decline in the quadrant in question times the total quadrant acreage;

"9. The determination of the acreage of the Canadian River Gas Company in the quadrant, and the application of the same principal to that acreage."

Mr. Spencer: How large is a quadrant?

The Witness: They vary somewhat in size.

Mr. Spencer: They are not uniform in size?

The Witness: Not exactly uniform, no.

"To be more specific about the method of balancing each quadrant against adjacent quadrants where isobar configurations indicate effective movement of gas, calculation of the production per-acre-pound decline, if based solely on the production from wells in that quadrant alone as against the weighted pressure of the quadrant, indicated a volume removed per pound in pressure drop clear out of proportion to that of adjacent areas.

"If there were gas moving into the quadrant from outside its boundaries, the production per-acre-pound would be high in relation to the acreage in the quadrant. If, on the other hand, gas were moving out of a quadrant, the per-acre-pound would be low. If the quadrant data alone were used, the results obtained would be an indication of availability of supply to the then existing wells in the quadrant, rather than indicating reserves in place. It is for this reason, it was necessary to balance quadrants, or areas adjacent to the one, together with the one in which it was desired to estimate the gas in place as the reserves in place.

"At this point, it should be pointed out, very definitely, that only by determining the available reserves existing in distinct and separate parts of the field can there be an estimate of reserves established applicable to any given productive local acreage.

"Averages of this field, as a whole, are always erroneous and misleading for the reason that by striking an average over a field of the size of the Panhandle field, gas is automatically assigned to areas that do not have the indicated reserve. For example, suppose two areas of equal size, one located some place in the eastern part of the field, and the other in the western part. The one in the west shows a reserve remaining of 26,000 Mcf. per acre, and the east shows a reserve remaining of 6,000 Mcf. per acre. The average would be 16,000 Mcf. per acre. Thus, 10,000 Mcf. would be deducted from the area of high reserves, and

10,000 Mcf. added to the area of low reserves. Under such a calculation, no one would be so gullible as to believe that a proper allocation of reserves had been made as to the gas bearing lands in the two localities.

"Furthermore, it is axiomatic that in anything made up of components having diverse characteristics, an average based on the whole is fallaceous and invalid for the reason that it does not weigh in the characteristics of its diverse component parts.

"Minimum Estimates

"The estimate is a minimum estimate because:

"1. Stabilization of pressures are seldom if ever reached during the 'closed-in' period prior to determination;

"2. During the period used for determination of reserves, only metered gas was employed. No estimate of wasted gas was made;

"3. The pressures were not calculated to reservoir conditions, but were well-head gauge pressures;

"4. Utilizing a 25-pound abandonment pressure well-head gauge, necessarily means a higher weighted pressure, because there would be no such well-head pressure if there were no high pressure at undrilled points. In other words, to have 25 pounds well-head gauge pressures at abandonment, necessarily indicates a pressure differential between the face of the producing formation in the well as against undrilled areas;

"5. Consideration was given to the deviation from Boyle's law, but was not applied. Its utilization would have given a somewhat higher result."

By Mr. Lange:

Q. Mr. Hammer, in connection with your work on this assignment in estimating gas reserves on the acreage of Canadian River Gas Company, I will ask you whether you prepared an exhibit entitled "Derivation of Weighted Gas Pressures"?

A. I have.

Q. Is this the exhibit I am now showing you?

A. That is right.

Mr. Lange: Will the stenographer please identify it?

The Trial Examiner: It will be marked for identification as Exhibit No. 179.

(Exhibit 179, Witness Hammer, marked for identification.)

Mr. Hammer then identified Exhibit 179 which was subsequently admitted in evidence, which Exhibit consists of a map prepared under his supervision and direction. This map portrays the Texas Panhandle Oil and Gas Field. The outlines of the map were taken from maps prepared by the Texas Railway Commission. The particular map is a reduction by photostatic process of original county maps that were on a scale of 4,000 feet to the inch. The Roman numerals on the map indicate the divisions or quadrants for each county.

The witness then read into the record a description of the map as follows (Vol. 51, pp. 7073-7085):

"1. Base Maps and Boundary Determinations:

"A. Base Maps:

"The base maps for the construction of closed-in wellhead isobars of the Texas Panhandle field are the county maps of the Browning Map Company, drawn to a scale of one inch equals 4,000 feet.

"Five sets of the county maps covering the Panhandle field were necessary—each set representing the pressure configuration of the summer of each of the years considered. Each set includes maps of the counties off Potter, Moore, Hartley, Hutchinson, Carson, Gray, Wheeler, and portions of Oldham and Collingsworth counties.

"B. Delineation of the Field Boundary:

"The first operation was the necessity of delineating the limits of gas productivity—the field boundary, thereby blocking out the area considered to be productive or potentially productive.

"The field boundary as determined and used by the Railroad Commission of Texas as of 1938 served as the boundary used for this reserve estimate. The field boundary was

carefully drawn upon each set of maps, care being taken to follow the Railroad Commission location exactly.

"On the northeast flank of the field both the field boundary and the gas-oil boundary, as delineated by the Railroad Commission, were plotted. In all cases the isobars were carried only to the gas-oil boundary upon the assumption that the inclusion of the area northeast of the gas-oil line, in the light of the lack of appreciable metered gas volumes and absence of closed-in wellhead pressure data, would introduce error. As far as can be determined, this area is restricted to oil production, with little evidence of potential gas productivity.

"One alteration of the field boundary is to be noted. March 30, 1938, the Stokely & Savage well, C. H. Beigel No. 1, was completed as a gas well in Section 63, Block 23, H. & G. N. R. R. survey, near the east south central border of Gray County. This well, having a closed-in wellhead pressure of 406 pounds in the summer of 1939, lies approximately 1¼ miles southwest of the field boundary as located by the Railroad Commission of Texas."

I might say the term "southwest" there means if it goes out west of the boundary it put it outside the boundary they previously had.

"It became necessary, therefore, to relocate the boundary in this area. The approximate position of the relocated boundary in that area is represented by the heavy dashed line southeast of the solid heavy line representing the Railroad Commission boundary. From available structural data, consideration of well logs of the adjacent wells and structural maps, it appears probable that potential gas reserves extend southwest of Gray County to the vicinity of the town of McLean. These data seem to indicate that a structural high exists in this area with porosity and productivity in strata existing down to approximately 400 feet above sea level.

"II. Pressure Data and Construction of Isobars

"A. Sources and Tabulation of Pressure Data:

"The closed-in well head pressures used were derived from photostatic copies of the production-pressure records of the Railroad Commission, supplemented by such pressure data

as were available from various company records. The pressure values were checked on both form 3 records and company records, wherever possible. In cases of serious discrepancies in pressure data, additional verification was requested from the company controlling the well under consideration.

"The pressure data were tabulated by wells for the 5-years under consideration, the 5 years from 1935 to 1939, inclusive, and each pressure was plotted at its well location on the county maps for each year. In all cases summer pressures were used, taken in July, August, and September.

"When it was observed that the recorded pressures of a well appeared to be erratic and fluctuated between high and low values over a period of time, special note was made of the pressures. Then the production history of that well was tabulated for the intervals between the dates of the recorded pressures in order to correlate withdrawal volume with pressure change. This procedure was extended to adjacent wells which might conceivably have exerted some influence upon the pressures under consideration. Also the log of the well and its history were consulted in order to note the effects that the mechanical condition of the well might have upon the pressures recorded. When it was observed that a well having a low pressure recorded one year showed a higher pressure in succeeding years, with no evidence of heavy withdrawals having depressed the pressure; it was assumed that the mechanical condition of the well was responsible or that the recorded low pressure was an error of measurement or recording. In such cases the position of isobars in the vicinity of the well were determined by the pressures of adjacent wells and the general isobar configuration of adjacent areas.

"B. Construction of Isobars:

"The equal pressure contours or isobars, based upon the plotted closed-in wellhead pressures, were drawn at 10-pound intervals. The procedure of drawing isobars through the plotted pressures is based upon the equal spacing of isobars according to a predicated uniform slope decline of pressure over the distance between the locations of the pressure measurements. That is, the pressure differential between the

two wells over the distance of separation of the two wells is contoured by equal map spacing of the 10-pound interval isobar lines.

"The various county maps for the five-year period 1935-1939 were carefully isobared according to the above procedure, except in those areas now dominantly oil producing; where closed-in well head pressures were scattered or almost entirely lacking. The immediate area adjacent to Borger, in the south central portions of Hutchinson County and the northwest and north central portions of Gray County are such areas. In these areas the recorded well pressures are the lowest in the field and tend to fluctuate erratically, with the records of the individual wells being characterized by pressure measurements scattered through the past history of the well at odd intervals and with frequent gaps. Under such circumstances weighted average pressures were determined for these 'oil areas' by noting the average pressures of areas of equal well density and similar pressure stage, and weighting these pressures by their areal distribution.

"In northern and western Moore County, Hartley County, Potter County, and Carson County are areas which, by the presence of wells at substantial distances from the field limits having pressures only slightly depressed from 430 pounds, and from the isobar spacing and configuration, appear to be undrained and at 430 pounds well head gauge. By extrapolating the isobar pressure decline slope of the areas under consideration to 430 pounds, isobar lines of 430 pounds were constructed. The position of this 430-pound line delimits approximately with the best accuracy possible, the remaining areas of substantially virgin field pressures.

"III. Possible Isobar Map of the Texas Panhandle Gas Field as of the Summer of 1939.

"Upon the completion of the isobaring and planimetering of the individual county maps, each map was photographically reduced approximately one-quarter in size and a mosaic of the whole Panhandle field made. This composite of county maps was then photographed and an enlarged negative made, from which blue line prints could be produced.

"The individual county maps upon which all isobaring and

planimetering was done were carefully matched and the isobars connected across the county lines. The matching of counties is virtually perfect where no errors in the original drafting of the maps are present.

"There are some areas in which appreciable drafting errors on the original maps are evident; the most marked discrepancies occur in the vicinity of the junction of Hartley, Moore, Potter, and Oldham Counties at the extreme western end of the field.

"The county map of Moore County was drawn in such a manner that the county line included portions of sections actually located in Potter County. The Potter County map, on the other hand, has the county line placed accurately with respect to the various sections. Hence, as can be seen, the sections and isobars on either side of the Moore-Potter County line do not match exactly, and an excess of acreage exists in Moore County on the Moore County map. Also the Potter County map is slightly off scale and skewed somewhat with respect to the north and south lines of the field.

"These discrepancies in drafting produced no errors in the isobaring or calculations, as care was taken to match the county lines of Potter and Moore correctly by overlapping when the isobars were connected across the county line. This overlapping is made evident by noting that on the composite map the isobars adjacent to the county line in western Moore and Potter stop short of the limits of the individual maps, but if the maps were overlapped in such a manner that the isobars joined, then each section and the county line would be in correct relationship one to the other.

"The skewness of Potter County precludes the overlapping of the Moore and Potter Counties of the composite map, without disturbing the continuity of the other boundaries of Potter County with adjacent counties. However, the smaller side of Potter and the skewness were balanced out as exactly as possible through the planimeter factor, and similarly the acreage of Moore County was reduced to the correct value by its planimeter factor and by planimetering only up to the true position of the county line, with respect to the individual sections.

"Such errors as may have resulted are extremely small

and will always be present in drafted maps. Invariably on all maps inspected, including the maps furnished the Commission by the Canadian River Gas Company, it was observed that the sections adjacent to the county lines in Potter and Moore Counties are reduced and subnormal in size.

"For example, Section 25, Block PMc, E. L. & R. R. Survey straddles the Moore-Potter County line and is labeled as being 662.6 acres. Its map area is 1.292 sq. in. In contrast, Section 33, E. L. & R. R., Block PMc, Moore County, is labeled 640 acres with a map area of 1.531 sq. in. The larger acreage unit has the smaller map area.

"It is to be remembered that the detailed configuration of any map is an approximation to the survey data, and that particularly in this region the survey data and general property lines leave much to be desired with respect to accuracy.

"The probable error in acreage as determined for Quadrant III Potter by planimetering tends to yield a slightly smaller acreage, which in the calculation of reserves tends to give a larger remaining reserve figure. This tendency is compensated for through the general tendency of the method to yield a minimum estimate. The net error is probably substantially less than five per cent, and will be conservative under any circumstances.

"Derivation of Acreages, Acre-Pound Values and Weighted Average Pressures

IV. Estimation of Quadrant Acreage

"Although the maps varied somewhat in scale, the field outlines and the quadrant boundaries were drawn in such a manner that if the maps were all adjusted to the same scale, the boundary lines would coincide. The size and shape of the quadrants were determined from consideration of two factors, the first being necessarily the limitation of the radius of action of the planimeter tracer arm. The second consideration is the desire and necessity of having each quadrant area include wells whose general pressure-production characteristics are similar or related with special regard to drainage configurations.

"The planimeter was run around the boundary of the

quadrant area. This reading (Reading 1) was recorded and checked by a verification run. The individual isobar areas (continuous areas bounded by isobar and boundary lines) were now measured individually by the planimeter and their readings recorded. When all the constituent isobar areas of a quadrant had been measured, the individual areas were totaled, and this sum was compared to the reading (Reading 1) of the entire quadrant area. If this total did not check closely with Reading 1, the area was replanimetered until a check was obtained.

"(It is necessary here to note that a single run around the boundary of the unknown area will give a closer approximation of the area than will the summation of the small isobar areas comprising the measured area. Whenever a planimeter run is made, errors arise from a combination of human and instrumental factors, the total error of which is in direct proportion to the length of line followed by the tracer point. The length of line traced in outlining the total area is much less than the summation of the perimeters of the constituent isobar areas. Hence the proportion of error to area for the single run around the entire area is less than the proportion of the sum of the constituent isobar errors to their total area.)

"V. Conversion of Planimeter Reading to Acreage

"In each of the quadrants there were large tracts of land of known acreage. To obtain a conversion factor between planimeter readings and acreage, the following method was used:

> "The planimeter was carefully run around the perimeter of the tract of known acreage and the planimeter reading noted. The known tract acreage was then divided by the planimeter reading to obtain a conversion factor between the planimeter reading and acreage. In each case as large a block of acreage which could be defined within the quadrant was chosen. This was done to get as representative a conversion factor as could be obtained in each case, consideration being given to size and distribution of tracts of known acreage throughout the quadrant."

The Trial Examiner: Mr. Hammer, right there in con-

nection with your quadrant, does this heavy square on the map indicate—

The Witness: You mean, for example, you will find the Roman numbers in the center?

The Trial Examiner: Yes.

The Witness: That represents the quadrant.

The Trial Examiner: That represents the quadrant?

The Witness: Yes.

Mr. Lange: You are now referring to the map attached to this exhibit?

The Witness: That is right.

"VI. Application of Conversion Factor

"The conversion factor was now applied to the summation of the isobar areas to obtain a total quadrant acreage and also to the individual isobar areas to obtain acreages lying between isobar lines. The acreage lying between isobar lines or isobar lines and the field boundary were now multiplied by the average of the boundary isobar pressures to obtain each acre-pound value. The summation of the isobar area acre-pound values within the quadrant constitutes the unadjusted acre-pound value for the quadrant.

"VII. Adjustment of Quadrant Acreages and Acre-Pound Values

"The quadrant areas in acres were calculated for each of the quadrants over the five-year series of maps. Hence there were five separate calculations of each quadrant acreage, each of which differed in value by a small amount from the others. To obtain an average acreage which could be used for all calculations, the five different acreages were added together and their sum divided by five. The quotient or average acreage was now considered the adjusted quadrant acreage for each of the five years and was used in further calculations.

"To obtain adjustment factors for each of the five years in order to adjust the yearly acre-pound values of the quadrants, the original quadrant acreage value was divided into the adjusted acreage value. The individual isobar acre-

pound values were then multiplied by this adjustment factor to obtain adjusted isobar acre-pound values. The sum of the isobar acre-pound values in a quadrant was considered the adjusted quadrant acre-pound value. (Adjustment of the acreages and acre-pound factors was necessary, for these values, together with production data, were to be used in a relationship in which all values must be commensurate. For example, if a quadrant acre-pound value for one year were to be compared to the same quadrant acre-pound value for another year, it is seen that the acre-pound values have to be calculated from the same acreage value, otherwise no true comparison exists.)

"VIII. Derivation of Quadrant Weighted Average Pressures for Each of the Five Years.

"The quadrant weighted average pressures were obtained by dividing each yearly quadrant acre-pound value by the quadrant acreage."

The witness further testified with respect to Exhibit 179 (the map) that the red line indicates the outer lines of all of the quadrants in which Canadian River Gas Company has producing acreage, and those are the lines to which he made reference in his statement that he just read, where an adjustment had to be made. The Arabic letter groups that appear inside the red lines represent the approximate remaining reserves per acre in Mcf. in the area of Canadian River Gas Company's holdings. The name "Amarillo" appearing at the lower left-hand corner of the map means the city of Amarillo, Texas.

The witness further stated in explanation of the map that the development in Potter and Moore Counties during the period from 1935 to 1939 had a very marked tendency to make a somewhat uniform pressure distribution over those areas, and that from 1935 to 1939, inclusive, there was an area running across Carson County and across and into Gray County beginning at the extreme southwestern corner of Hutchinson County, Quadrant 3, and cutting across the extreme northern part of Quadrant 4, Carson County; across Quadrant 3, Carson County, and across Quadrant 2, Carson County, and into Quadrant 4 in Gray County. The pressure decline in this area has been normal for the area, but there

has been a marked drop in isobars across that territory that has been constant from the beginning up to the present time. The witness stated that he did not know what caused this, but he did think it was very significant. He stated that it could be an area of low permeability, or it might be caused by some change is deposition, but whatever the cause, the situation has remained constant over the period.

The witness then stated that he had prepared another exhibit entitled, "Statement of Gas Reserves and Method of Calculation, Canadian River Gas Company," which is Exhibit 180. This exhibit was then identified and later received in evidence, over objection of Company counsel.

The objection and ruling of the examiner is reflected by the following (Vol. 90, pp. 13657-13660):

Mr. Keffer: If the Examiner please, the respondents object to the admission of Exhibit 180 prepared by Mr. Hammer for the reason that the exhibit is wholly irrelevant, incompetent, immaterial for various reasons and among those reasons is the fact that Mr. Hammer has stated repeatedly upon his cross examination that he did not take into account the geology of the field producing formations as such, their characteristics, and has eliminated from all consideration many factors which would necessarily affect the result and which must necessarily be considered if a correct result is to be reached; and stated finally his approach was that of a mathematician's approach to the problem, merely taking into account weighted average decline pressures as he determined them with respect to production.

It is our position that his background in this method is wholly insufficient to reach any result that is entitled to any consideration whatsoever. In enumerating briefly some of our specific objections to the exhibit I do not mean in any sense of the word to limit our objections to those specific matters detailed but resting upon the general objection that the exhibit is wholly irrelevant and incompetent and immaterial.

Mr. March: Mr. Examiner, most of the objections have gone to the merits of the exhibit rather than to the competency of the exhibit and the materiality of the exhibit. Mr. Hammer testified in applying the pressure decline method

as he applied it he applied it to the whole and as to the Canadian River acreage that automatically drainage was one of the things taken into consideration;

Not only that, his method applied here is a method which has been applied by other persons in estimating reserves in the Panhandle field of Texas and it is a well established and well known method. It has scientific backing and we feel that it is competent; it is relevant—it is relevant alone because there have been exhibits heretofore offered and put into evidence by counsel for the company utilizing another method, the porosity thickness method, and certainly an estimate of reserves is most competent and most relevant in this case if we are going to determine in any respect the life of the reserves in the field.

The fact of the business is we couldn't determine this rate case unless we had some evidence of the life of the field and the life of the Canadian River reserves in the field.

The Trial Examiner: In so far as the Examiner is concerned, the Examiner is satisfied that the study presented has been presented by an able and competent geologist and he has employed a recognized method.

Now, the matters he did consider or did not consider to me go to the weight to be given to the study rather than to the admissibility of the study and inasmuch as this evidence is carefully weighted, it seems to me that it would do no harm for it to come into the record.

On the grounds stated the objection will be overruled and Exhibit No. 180 will be received.

The witness then read a prepared statement as follows (Vol. 51, pp. 7089-7101):

A. "The future remaining gas reserves under land controlled by the Canadian River Gas Company in the Texas Panhandle field are summarized as follows:

"1. All calculations arriving at the reserves are made on a pressure base of 14.65 pounds absolute. The pressures taken were well head closed-in pressures.

"2. The determinations were made by the application of the principles of Boyle's Law.

"3. The estimate of remaining reserves of gas beneath the lands of the Canadian River Gas Company as of August 1, 1939, are 3,645,213,000 Mcf., calculated to a 25-pound well-head abandonment pressure."

At that point I wish to call attention to the fact that there is a slight discrepancy there between the figure presented and the figure that I gave to the accountant. That discrepancy—

Q. When you are referring to the figure you gave the accountant, is that 3,645,213,000 Mcf.?

A. Yes, sir.

Q. Very well.

A. It was brought to my attention by the fact that I couldn't estimate or couldn't arrive at the exact amount of acreage assigned to the Canadian River Gas Company in one or two certain areas. It was impossible to assign more acreage to an area than actual planimetering of the maps indicated. That brought about that small discrepancy there. It amounts to only—well, it is only three or four-tenths of one per cent. It was so small that I didn't see any reason why it should be called to the attention of the accountants so that they would be required to recalculate the work.

Q. Very well.

A. I will read that again, starting with Paragraph 3.

"3. The estimate of remaining reserves of gas beneath the lands of the Canadian River Gas Company as of August 1, 1939, are 3,645,213,000 Mcf., calculated to a 25-pound well head abandonment pressure.

"4. The calculated ultimate reserve beneath these lands is, to zero well head pressure, 4,269,165,000 Mcf.; and to an abandonment pressure of 25 pounds, the estimate is 4,018,609,000 Mcf.

"5. At an assumed annual withdrawal of 50 billion cubic feet, the remaining reserves will last for a period of 73.7 years.

"Details of the method used and tabulation of basic data follow in this exhibit."

Q. Will you explain in connection with each of these

tables and charts that are appended to the exhibit; first, your Table 1 following the written statement, and tell us exactly what the nature of the calculations is that appear on that table?

A. That is a tabulation of the years, the quadrant acreage, quadrant acre-pound factor, quadrant weighted average pressure and accumulated production for all quadrants that were utilized in this estimate.

Q. Now, your Table 2, turn to Page 3.

A. Table 2 is a sample calculation showing the solution by which we arrived at the Mcf. per acre-pound decline from a simultaneous equasion derived from the method of least squares.

Q. I notice that the data appearing here was taken from Table 3. Is that the following table?

A. Yes, that is right.

Q. Will you relate that to this Table 2?

A. I think I can best illustrate that by stepping to the map.

Q. Very well.

A. Quadrant 3 that we used, for an illustration, is this triangular area here in the northwestern part of Potter County. We realized that no one could arbitrarily draw a line and say that the area within—the line delimiting that area would not be affected by adjacent areas, in order to arrive at a fair determination of the problem.

Furthermore, wells noted over a period of five years indicated there have continually been a low pressure area in that part of that Quadrant.

Q. Speaking of Quadrant 3, Potter County?

A. Yes. The configuration of the isobars over the five-year period indicated that there was a larger percentage of gas, a larger amount of gas, rather, being produced out of this area—

Q. Speaking now of Quadrant 3?

A. —than seemed to be warranted from the withdrawal of the surrounding isobars. To arrive at the production per acre-pound of this area we took in this area—

Q. Hartley County, which the red figures "13,713" indicates?

A. There is only one quadrant there so we didn't indicate it.

Q. I see.

A. Quadrant 3 of Moore County, Quadrant 2 of Moore County, Quadrant 3 of Potter County and Quadrant 2 of Potter County. We determined from those the production per acre-pound decline and applied it to Quadrant 3.

Q. That is Potter County.

A. Potter County.

I might state that same principle has been followed through in the entire calculations in this exhibit. While it moves from west to east—it would apply the other way—when we came over to determine the reserve of Quadrant 2—

Q. Potter County?

A. Potter County.

—we eliminated Hartley County, but we utilized Moore County, Quadrant 2, Moore County, Quadrant 3—

Q. Potter County?

A. Potter County.

—Potter 2, Potter 1, and Moore 1, to arrive at it, and took the production per acre-pound decline and applied it to that Quadrant.

Q. Quadrant 2?

A. Quadrant 2.

—and it likewise eliminates those to the west that were not immediately adjacent to the area in question.

Q. Now, turn to Page 4, Exhibit 180, Mr. Hammer—

A. All right.

Q. You have there an explanation of the construction of curve. What curve are you referring to in this exhibit?

A. I am referring to the curve immediately following the statement.

Q. Appearing at Page 4 of the exhibit?

A. That is right, appearing at Page 4-B of the exhibit. It is entitled "Quadrant Group Decline Curve, Quadrant III, Potter County, Texas."

Q. You may proceed with that explanation.

A. "The same groups of quadrants, together with their total acreage, weighted pressures and accumulated production for the mathematical determination of the gas reserves of Potter County, Quadrant III, as are used in the sample calculations, are also used here.

"The slope of the curve is determined by multiplying the total acreage (229.712A.) by the previously determined production per-acre-pound decline (35.1 Mcf.), arriving at a factor of 8,062,891; then arbitrarily choosing some pressure on the pressure decline scale, subtract this pressure from the original 1935 pressure, then multiply such drop in pressure by the factor of 8,062,891.

"The points on this curve were determined by the following data:

"Pressure decline in pounds—"

The Trial Examiner: I don't think it will be necessary for us to read these figures. The reporter will copy them in.

(At the direction of the Trial Examiner, the following statement was copied into the record:)

422.7 — 400 equals 22.7
422.7 — 375 " 47.7
442.7 — 350 " 72.7
422.7 — 325 " 97.7

Then— 8,062,891 x 22.7 equals 183,027,626 Mcf. at 400 lbs.
8,062,891 x 47.7 " 384,599,901 " " 375 "
8,062,891 x 72.7 " 586,172,176 " " 350 "
8,062,891 x 97.7 " 787,744,451 " " 325 "

The Witness: "The projection of the curve arrives at a figure of 3,207,000,000 Mcf., ultimate reserve from August 1, 1935 to an abandonment pressure of 25-pounds well-head gauge, 422.7 lbs. — 25 lbs. equals 397.7 or functional pressure to well-head abandonment of 25-pound gauge.

"397 x 8,062,891 equals 91,356,462

"3,207,000,000 divided by 91,356,462 equals 35.0999 (35.10) Mcf. per-acre-pound decline, also the functional pressure

"397.7 x 8,062,891 equals 3,206,611,751 Mcf.

"After the curve had thus been constructed, the pressures for 1935, 1936, 1937, 1938 and 1939 were plotted against the accumulated production showing the proper position of those points on the projected curve.

"There is thus shown that the method of calculating the

production per acre-pound decline by the simultaneous equations derived from the application of the method of least squares, is fair, applicable, and as exact as supporting data will permit."

* * * * *

Q. On Page 4, Paragraph 2, you refer to the total acreage of 229,712 acres?

A. Yes, that is the total acreage embraced in all these quadrants that were used for the determination of the acre-pound. In other words, it is for that acreage embraced in this area here. It embraces the area of Quadrant 2 and 3, Potter County; Quadrant 2 and 3, Moore County, and that part of the territory in Hartley County.

Q. What relation does the total acreage have to the total acreage of Canadian River Gas Company, for instance?

A. Well, this factor hasn't any relationship that I am using now.

Q. It has none?

A. No.

Q. It has no place in this picture except that it is the total acreage you used in developing your formula?

A. That is right, and in arriving at the production per acre-pound.

Q. That is the only purpose of the total acreage shown here?

A. That is right.

By Mr. Lange:

Q. Now, Mr. Hammer, tell us about the curve at Page 4-C.

A. I made no written statement on that because it occurred to me that it was almost self-explanatory. The title of Curve 4-C is "Enlarged Partial Group Decline Curve, Quadrant, Quadrant III, Potter County, Texas." That means the same data, the same information and a portion of the same curve as on the preceding curve on Page 4-B. The purpose of this curve or this partial curve as is stated on the curve itself "Illustrating that calculated decline curve not only follows the straight line characteristics of pressure decline versus accumulated gas withdrawals, but gives a truer and more conservative slope than interpolated construction."

The three lines of the three curves, of them "A" was drawn to indicate the probably maximum decline curve that

anyone could draw on the data at hand—I mean, draw it without any mathematical calculation, it would be the most probable decline in relation. In other words, if you drew that Curve B simply placing a straight edge on there and trying to get the proper spacing as between all of these various points, that would probably be the slope that would be decided by the average engineer.

Curve C is a decline curve based on factor of 35.1 Mcf. per acre-pound decline as determined by mathematical method. The curve drawn through the large circles on this is the slope determined by the mathematical calculation.

Those smaller circles are the accumulated production for this area utilized plotted against the weighted pressures for each one of the five years. The purpose of that curve is to illustrate that the slope of the curve as calculated not only follows the decline as it should against volume removed but also shows that the method is more conservative, at least in this case, than if someone would draw the curve manually.

* * * * *

I would like to refer back a moment to the curve on Sheet 4-B. It is the only thing I believe I didn't explain on this curve and that is the large circles represent the calculated points based on the 35.1 production per acre-pound, and the small circles represent the points where accumulative production is plotted against pressures. I don't believe I mentioned that before.

The point there is to illustrate that the calculated slope will fall at the proper position as against the accumulated production plotted against the drop in pressure. That is the only point that I wanted to explain regarding that.

Q. That is all in regard to Curve 4-B?

A. That is right.

Q. Now proceeding to Table 4 and Table 5, Page 4 of 4—

A. Tables 4 and 5—haven't we missed Table 3?

Q. That is right. You had just referred to the relation.

A. Table 3 simply shows the various groups of areas or Quadrants that were utilized in arriving at a production per acre-pound decline factor for each of the quadrants

in which Canadian River Gas Company has producing acreage.

Q. All right, Now, Table 4?

A. Table 4 shows the calculated remaining reserve for the entire quadrant in which the Canadian River Gas Company has producing acreage, and Table 5 shows the calculated remaining reserve of the Canadin River Gas Company as of August 1, 1939, gas in Mcf. at 14.65 pounds per square inch absolute.

This table shows the quadrant in question, the weighted average pressure for 1939, the functional pressure—now, that term "functional pressure" represents the difference between weighted averages of August 1939 and abandonment pressure of 25 pounds well-head gauge. I believe I explained this situation previously.

* * * * *

Q. On Table 4 you show the remaining reserve at 25 pounds abandonment pressure for the sum total of your various quadrants used there, is that correct?

A. The remaining to 25 pounds abandonment pressure.

Q. In Table 5 you show remaining reserve in Canadian River Gas acreage without any reference in your title to 25 pounds abandonment pressure. Am I correct in assuming, however, if you applied your note indicated by the asterisk in each instance you would arrive at the same point, whether it is in the title or not?

A. That is right, they are both on the same basis.

* * * * *

A. The total reserve there is simply a summation of the calculated reserve for the Canadian River Gas Company productive acreage in each quadrant. That remaining reserve per acre over there is derived by dividing the estimated remaining reserve by the total acreage in the quadrant and those are the figures that are placed on that map; that is, the figures in red.

Q. The map is in Exhibit No. 179?

A. That is right.

Q. The acreage figures in red pencil on the map is in Exhibit No. 179?

A. Yes. They are simply placed on there to give sort

of a graphic picture of the variables in remaining reserve over the area.

The witness then read into the record a further explanation of Exhibit 180 as follows (Vol. 51, pp. 7101-7109):

"As the gas reserves in each quadrant were all calculated by the same method an illustration of the method is given in the case of one of them. Illustration example; Quadrant III Potter County.

"I. Grouping of Quadrants.

"In order to obtain the accumulated production versus pressure decline relation for this quadrant, it was first necessary to choose those quadrants immediately adjacent to Quadrant III which, after a study of isobar configurations, indicated the truest relationship between production and pressure factors having an effect on that quadrant. The data from these quadrants was then grouped together with that from Quadrant III for the purpose of deriving a production per acre-pound decline value.

"II. Basic Data, Table I.

"The basic data of each of the Quadrants entering into the calculations of those quadrants in which the Canadian River Gas Company owns acreage is found in Table I. This contains a summary of quadrant acreages, quadrant acre-pound values, quadrant weighted average pressures and quadrant accumulated production since August 1, 1935 to August 1, 1939.

"The quadrant acreage in Column D, the quadrant acre-pound values in Column E, and the quadrant weighted average pressures in Column F were derived as explained in a preceding section entitled 'Derivation of Acreages, Acre-pound Values and Weighted Average Pressures.'

"The weighted average pressure in Column F is derived by dividing the acre-pound value in Column E by the quadrant average in Column D.

"III. Calculation Data, Table III.

"Table III contains the tabulated data for the calculation of reserves in all quadrants having acreage owned by the Canadian River Gas Company as explained in accord-

ance with the criteria shown in Paragraph 1, grouping of quadrants.

"The combination of quadrants for the calculation of the production per acre pound decline value for quadrant III Potter was chosen from table III. These data are found in Column A, Lines 20 and 23, the years Column B, the total acreage of the group in Column C, the group acre-pound value in Column D and the group accumulated production from August 1, 1935 to August 1, 1939 in Column F. The group weighted average pressure, Column E, was obtained by dividing the group acre-pound value for each of the years by the constant group acreage.

"The group acreage (col. C, line 21), the group weighted average pressures from 1935 to 1939 (column E, lines 21 to 25), and the group accumulated productions from 1935 to 1939 (column F, lines 21 to 25) were taken from table III for the sample calculation of Quadrant III Potter shown on table II.

"IV. Sample Calculation, Table II:

"Table II illustrates the method followed to derive a production per acre-pound decline value for reserve acreage. The weighted average pressures versus the accumulated production data (table II) can be interpreted by the straight line equation: (See table II A. Graph of Quadrant III Potter data)

"$P = a - b\,Q$ where

"P is weighted average well head closed in pressure (Column C)

Q is the accumulated production by years from August 1, 1935 corresponding to P (Column D)

a and b are constants to be determined.

a; representing the pressure at zero production

b; representing the rate of change of pressure with production (gas withdrawal). Q.

"By the reasoning of the method of least squares the constant b may best be determined from the following two simultaneous equations.

"Eq. (1)

$$SP = Na - bsQ$$

"Eq. (2)

$$SPQ = aSQ - bsQ^2$$

"Where N = the number of data points. (In this case 5)
"SP = the sum of the P's (P = Pressures)
SQ = the sum of the Q's (Q = Volume of gas removed* (S = Summation)
SPQ, is the sum of the products of each P multiplied by the corresponding Q (i.e. 419. S in Column C, line 2 x 26,020,994 in Column D, line 2), and
SQ^2 is the sum of the squares of each Q [i.e. $(26,020,994)^2$ Column D, line 2 = 67.709213×10^{13}, Column F, line 2]

"Eq. (3)

Multiplying equation (1) by $\frac{SQ}{N}$ we obtain

$$\frac{SP.SQ}{N} = aSQ - \frac{b}{N}(SQ)^2$$

"Eq. (4)

Subtracting equation (3) from equation (2)

$$SPQ - \frac{SP.SQ}{N} = bSQ^2 \text{ plus } \frac{b}{N}(SQ)^2$$

"Solving for b in equation (4)

$$b = \frac{SPQ - \frac{SPSQ}{N}}{\frac{(SQ)^2}{N} - SQ^2} = \frac{NSPQ - SPSQ}{(SQ)^2 - NSQ^2} = \frac{SPSQ - NSPQ}{NSQ^2 - (SQ)^2}$$

"Now b is the change in weighted pressure for a change in production for the group 4 area. Since it is desired to know the change in production for change in weighted pressure for one acre, we take the reciprocal of b (i.e. $\frac{1}{b}$) and divide the reciprocal by the group acreage A, giving

"Eq. (5)

$$\frac{1}{Ab} = \frac{NSQ^2 - (SQ)^2}{A(SPSQ - NSPQ)}$$

"Equation 5 was then placed in line 7 of table II. When the proper values are substituted in this last equation and

the solution completed, it results in a value of 35.10 Mcf. per acre pound decline.

"This value is inserted in column G, line 25, of table III, column G, line 7 of table IV and column G, line 18 of table V where it is used to calculate the remaining reserves for the Canadian River acreage in table V and the remaining reserves of the quadrant in table IV.

"V. Remaining Reserves of Quadrants Containing Acreage of the Canadian River Gas Company, Table IV.

"The acreage for Quadrant III Potter County was obtained from table I (Column D, Line 21) and inserted in table IV (column E, line 7). In like manner the 1939 weighted average pressure of Quadrant III was obtained from table I (Column F, line 25) and placed in table IV (column C, line 7). To obtain the effective drop to an abandonment wellhead closed-in pressure of 25 pounds per square inch gauge, 25 pounds was subtracted from this weighted average pressure and the result tabulated in table IV (column D, line 7). The effective acre-pound value for the pressure decline to abandonment was then obtained by multiplying the acreage (column E, line 7) by the effective pressure drop (column D, line 7) and tabulating the result (column F, line 7). The acre-pound decline value (column F, line 7) multiplied by the production per acre-pound decline factor (column G, line 7) yields the Quadrant remaining reserve as of August 1, 1939 (column H, line 7). This remaining reserve divided by the quadrant acreage of 33389 yields the average remaining reserve per acre for the quadrant (column I, line 7).

"The reserves and the average reserves per acre for the other quadrants were derived in exactly the same manner.

"VI. Remaining Reserves of Canadian River Acreage, Table V.

"The values in table V were computed in exactly the same manner as they were in table IV, with the exception that the weighted average pressures of Canandian River acreage lying within Quadrant III Hutchinson County, and Quadrant IV Carson County, Table V (column C, lines 14 and 15) did not happen to coincide with the weighted average

pressures of the two quadrant acreages, Table IV (column C, lines 3 and 4). In the majority of quadrants, the Canadian River acreage was well enough distributed over the high and low pressure acreas so that its weighted average pressure would be very close to the weighted average pressure of the quadrant. However, in Hutchinson III and Carson IV, the acreage happened to be concentrated in areas of higher pressure than the average of the respective quadrants; hence, separate calculations were made to obtain the weighted average pressures of the acreage in Hutchinson III and Carson IV, according to the Canadian River acreage's areal pressure distribution. The Canadian River acreage weighted average pressure was then employed, as was the quadrant weighted average pressure in the other examples, to obtain the remaining reserves for Canadian River acreage in Hutchinson III and Carson IV.

"The remaining reserves and the average remaining reserve per acre values for Canadian River acreage were then tabulated in Table V (columns H and I)."

By Mr. Lange:

Q. Is there any other matter in connection with this Exhibit No. 180 which you believe should be given further description or that you should amplify at this time or clarify in any respect?

A. I think of nothing else at the moment.

Q. And the estimate of reserves as stated on Page 1 of your Exhibit 180, Canadian River Gas Company, are those as found by you as of August 1, 1939?

A. Yes, sir.

Q. And in your opinion from the line of your experience and the examination of the materials had and all of the information available, it represents in your opinion the correct estimates?

A. It is without doubt the best judgment. The methods used and the determination of the reserves at which I arrived were in my opinion the best that can be determined for the area under consideration.

Q. In Exhibit No. 180 or Exhibit No. 179 no attempt is made by you to either discuss or in any way give any opinion with reference to any matters of drainage?

A. No, except this, that in the utilization of the isobaric method of the determination of gas reserve, the method automatically takes into consideration certain drainage factors. If it did not take into consideration certain drainage factors; it wouldn't be applicable for usage but it has automatically taken into consideration certain factors.

Q. Those will be presented in a subsequent statement with reference to drainage?

A. There will be a subsequent exhibit and discussion of the question of drainage as a whole.

The witness further testified as follows (Vol. 51, pp. 7109-7120):

Q. You have just stated in answer to Mr. Lange's last question that your isobaric method; the preparation of the map with the isobaric contours on it did take into account automatically some of the methods of drainage?

A. That is right.

Q. I take it it doesn't adjust itself completely to the drainage question?

A. No, that is right.

Q. Would you mind stating what those elements are pertaining to drainage that you did take into account?

A. Automatically the construction of isobars indicate the differential in pressure between low and high pressure areas.

Q. I understand that, but from the standpoint of estimating a reserve I was wondering how that is accounted for in any drainage or took any drainage into account.

A. I hoped that I explained that a while ago. That was one of the reasons why we grouped these very quadrants, to arrive at a determination of the acre-pound factor, because a study of the isobaric maps over a period of five years indicated there was a drainage to and from it and that has been taken into consideration.

Q. That is, you took it into consideration in determining the outside lines of your quadrant areas?

A. Well, I don't know that I understand exactly what you mean.

Q. Maybe I didn't make it clear and I don't think I quite understood you, and I don't intend to get into the drainage question either.

My only thought was to clarify in my mind, at least, the

extent to which these isobar contour lines, if you term them that, took into account drainage in any manner whatsoever insofar as calculating the reserve in each of your quadrant areas.

A. I think I can answer it this way: The area, that is, the quadrants utilized in arriving at a production per acre-pound factor are so sufficiently large that they cover, at least have covered during the five-year period any area that might have any bearing on the question of the movement of gas to or from the areas in which the Canadian River Gas Company has acreage.

Q. Yes, I understand that. Let me ask you this and it may clarify it somewhat: Your isobar lines show different pressure gradients, that is, they are constructed on a basis of 10-pound variances in pressures between each line, is that correct?

A. Yes.

Q. Now, your flow of gas is in what direction from the standpoint of your map as shown by your isobar lines on there?

A. As a usual thing it is at right angles.

Q. That is right. It is from the high pressure or high pressure isobar lines to the next lower pressure and on to the next lower and on, and on just like water running down hill, isn't it?

A. That is true. The very fact that you may have low and high pressure areas—that is what I meant when I said it automatically considered those.

Q. I was wondering if that was what you had in mind regarding that.

A. Yes.

Q. In other words, take your own map. Near the four corners of Monroe, Hutchinson, Potter, and Carson Counties your isobar lines there show a pressure just cutting the four corners there of how much?

A. Well, that isobar there is 360 pounds.

Q. 360 pounds?

A. Yes.

Q. Then the next line to the southwest is 370 pounds, is it not?

A. 370 as you go south, that is right.

Q. And the next to the southwest is 380 and on and on at 10-pound intervals?

A. That is right.

Q. Now, with just as that is illustrated, take your *reservour* conditions on your isobar line indicated by 390 with reference to your isobar line shown as 360. You would have a 30-pound differential in pressure there, wouldn't you?

A. That is true.

Q. And the movement of gas underground would be in what direction between those two points?

A. I will have to qualify my answer there.

Q. All right.

A. It doesn't necessarily mean there is a movement of gas for the simple reason that these wells existing in the area between your 380 and 370, the gas withdrawn from the wells in that area have been largely responsible for that pressure differential and not in any long distance drainage.

Q. All right, suppose you shut those wells in for the time being and then what would happen?

A. If you could assume a condition where a person would shut his wells in for a year or two you might have drainage.

Q. Aside from drainage, you have a movement of gas from high pressure areas to low pressure areas?

A. There is no argument about that on the average.

Q. All right, and except as it may be influenced by producing wells as you have just stated, your isobar map would indicate very definitely and very specifically the movement of the gas underground assuming that it is moving?

A. With the exception that the migration factor is very largely affected by the permeability factor. It won't be the same at all points.

Q. That is very true. You will find it is moving more rapidly in some areas than in other areas?

A. That is correct.

Q. I appreciate that. Now, Mr. Hammer, you have designated on your quadrants a figure which determines, as I take it, the reserve remaining per acre in each of those quadrant areas?

A. Yes, that is right.

Q. Do you have the figures on that readily available showing what your original reserves were in each of those quadrants where you show the remaining reserve?

A. I don't know that I have it here. I will see.

Q. Well, if you can get that—you needn't get it right now, but we would like to have that.

A. Well, I have got it here.

Q. All right. you stated in one of your statements, I believe, that it was extremely difficult—in fact, you stated it a time or two, as I construed it, extremely difficult to take an isolated area and determine the reserve of gas in that area without considering its relationship to the surrounding areas?

A. To the immediately surrounding areas.

Q. Yes. All right, now, with respect to the determination of the reserves of Canadian River, you necessarily had to a very great extent at least, consider the field-wide picture, did you not, Mr. Hammer?

A. No, I did not.

Q. You didn't?

A. No.

Q. Have you considered the field-wide picture with respect to reserves generally in the Panhandle area?

A. Only in just a passing way, is all.

Q. In other words, you have made no estimate of the reserves in the Panhandle field as such?

A. I have made a general estimate, largely for the purpose of general information only.

Q. And as a matter of comparison, I take it. The two are so closely associated you almost had to have that, didn't you, to test your work on Canadian River?

A. No, I didn't have to have that at all.

Q. You didn't?

A. No.

Q. Well, did you in any event arrive at such a figure in connection with this work?

A. I arrived at a figure for the total field, future reserve.

Q. Well, I am wondering, in fact, as we view the matter, at least, it would be necessary for you to take the overall picture and your determination of the overall picture to get any satisfactory approach to the Canadian River picture, and in view of that our geologists would like to go over your working papers with you to that extent and determine the relationship between the two, at least from our theory, even though it might not be true as to yours.

Mr. March: If it please the Examiner, as far as that information is concerned, we will make available all working papers relative to the estimated reserves of Canadian River acreage as covered in this exhibit, but Mr. Hammer has testified that he has not prepared in connection with his estimate of reserves of Canadian River an estimate of the reserves of the entire field. He is not here offering an exhibit which shows the estimates of reserves of the entire field. If that were done, why, we—and we had prepared such an exhibit to offer, we would be glad to make available any working papers in regard to that exhibit.

Now, Commission's counsel's position, Mr. Keffer, is this, that we will make available to you all working papers relative to this exhibit. Now, I know that you are interested in the overall picture of the entire field—

Mr. Keffer: Very much.

Mr. March: Incidentally, we are not. We are interested in Canadian River's acreage directly, and so that is our position, but we will make available all working papers that we possibly can.

If there is any disagreement as to that, we can discuss that this evening and clear it up. That is our position.

Mr. Spencer: Well, Mr. Examiner, I am glad we have reached this point, that if a witness says that he has done something in connection with this study and his working papers or something else that he may have utilized in that connection are not available, we should have known that a long time ago. The witness said that he did make a figure on the gas reserves of the field in connection with his work here. Now, certainly it is competent, material and relevant to the issues we are here discussing, and I am not asking for any more working papers that he has, but whatever working papers he may have in connection with that field reserve figure, I think we are entitled to examine them.

Mr. March: We aren't offering an exhibit that gives the reserves of the field. Mr. Hammer says that that was not essential to this exhibit at all, that he does have some idea that if this method were applied to the entire field, he has some idea as to what the final figure would be, but as to an

exhibit and as to working papers in regard to that, we do not have them nor are they available for examination nor are we offering an exhibit in that regard.

We are making available all of the working papers in regard to this exhibit, however. An estimate of the reserves of the entire field has absolutely no bearing whatsoever on this particular exhibit. We don't have such an exhibit to offer in this case.

Mr. Spencer: I would suggest that the Examiner ask the witness what he has got.

The Trial Examiner: I feel like this, Mr. Spencer, with regard to these working papers, that unless counsel voluntarily makes those papers available which pertain to matters that the witness perhaps has considered but is not going to testify to in this proceeding, I feel that I have little, if any, discretion in that matter.

Now, if the witness undertakes to testify as to the total reserve in the Panhandle field, I think that would present a slightly different picture, but his testimony, as I understand it, will be confined entirely to the reserves underlying the acreage of the Canadian River Gas Company and if Commission's counsel makes the working papers underlying this particular exhibit available, which they have agreed to do, why, it seems to me that the Examiner would have little discretion in the present controversy.

Mr. Spencer: The Examiner may be right, and, of course, we would be bound by his ruling. If counsel wants to hold back anything related to the reserves in this field or acreage, I think we are on a different basis now as to making available working papers. We certainly have held nothing back.

Mr. March: Mr. Spencer, we are not going to hold one thing back in regard to this exhibit. Now, I know you gentlemen would like to have us present an estimate of reserves of this entire field. We have determined that that is not necessary to arrive at the Canadian River acreage reserve. We have not done that. We have no working papers and no exhibit to offer in that connection. You have got to have an exhibit before you can have working papers; so we have no

papers on the entire fields whatever, and we don't want to hold back one thing.

By Mr. Keffer:

Q. Mr. Hammer, have you arrived at a figure for the field as a whole?

A. You say, had I arrived at a figure?

Q. Yes, a figure with respect to the reserves in the Panhandle field as a whole.

A. As I stated, on academically, a figure that until I have done more work I would not want to attempt to support.

Q. Well, in taking into consideration the Canadian River reserve you have considered a lot of acreage that is not Canadian River acreage, didn't you? Your map here shows that.

A. Oh, yes.

Q. That's right, you went beyond the confines of the Canadian River block, so to speak, and considered some of Texoma, Panhandle Eastern acreage, Shamrock and acreage of many other producing companies.

A. I wasn't at all interested in who owned the acreage or anything of that type.

Q. That is very true, yet you did—

Mr. Spencer: Just a minute.

The Witness: The only reason that that acreage was utilized was to cover a sufficiently large area so that I would be in the position of having all of the area in that would have any direct bearing on the areas in which Canadian River had its acreage.

The following tables and plats were attached to and formed a part of Commission Exhibit 180:

SAMPLE CALCULATION

OF PRODUCTION PER ACRE-POUND DECLINE

Quad. III Potter County Illustrated

ata Taken From Table III Summary
(Production Per Acre-Pound Decline
Basic Data)

Year	A Group Acreage	P Group Weighted Average Pressure	Q Group Accumulated Production	PQ	Q^2
1935	229712 ●	422.7	0	0	
1936	●	419.8	26020994	10.923618×10^9	67.709213×10^{15}
1937		416.0	64177363	26.697779×10^9	$411.873264 \times 10^{15}$
1938		411.1	108357786	44.545086×10^9	$1174.140979 \times 10^{15}$
1939		402.8	156145362	62.895352×10^9	$2438.137407 \times 10^{15}$
		●P = 2072.4	●Q = 354701495	●PQ = 145.062680×10^9	●Q^2 = $4091.860863 \times 10^{15}$
(A)	(B)	(C)	(D)	(E)	(F)

$$\text{Production Per Acre-Pound} = \frac{N\,\bullet Q^2 - (\bullet Q)^2}{A(\bullet PQ - N\,\bullet PQ)}$$

$N = 5$

$N\,\bullet Q^2 = 5 \times 4091.860863 \times 10^{15} = 204.593045 \times 10^{15}$ (M.C.F.)^2

$(\bullet Q)^2 = (354701495)^2 = 125.81315 \times 10^{15}$ (M.C.F.)^2

$\bullet PQ = 2072.4 \times 354701495 = 7350.834 \times 10^6$ (Pounds x M.C.F.)

$N\,\bullet PQ = 5 \times 145.062680 \times 10^9 = 7253.1315 \times 10^6$ (Pounds x M.C.F.)

$N\,\bullet Q^2 - (\bullet Q)^2 = 204.593045 \times 10^{15} - 125.81315 \times 10^{15} = 78.779895 \times 10^{15}$ (M.C.F.)^2

$\bullet PQ - N\,\bullet PQ = 7350.834 \times 10^6 - 7253.1315 \times 10^6 = 9.7702 \times 10^6$ (Pounds x M.C.F.)

$A = 2.29712 \times 10^6$ Acres

$$\text{Production Per Acre-Pound Decline} = \frac{78.779895 \times 10^{15} \text{ (M.C.F.)}^2}{2.29712 \times 10^6 \text{ Acres} \times 9.7702 \times 10^6 \text{ (Pounds x M.C.F.)}} = 35.10 \text{ M.C.F./Acre-Pound}$$

COLORADO INTERSTATE GAS COMPANY, a corporation, PETITIONER,

vs.

FEDERAL POWER COMMISSION; CITY AND COUNTY OF DENVER, COLORADO; PUBLIC SERVICE COMMISSION OF WYOMING; COLORADO-WYOMING GAS COMPANY; and CANADIAN RIVER GAS COMPANY, RESPONDENTS.

No. 2551.

CANADIAN RIVER GAS COMPANY, a corporation, PETITIONER,

vs.

FEDERAL POWER COMMISSION; CITY AND COUNTY OF DENVER, COLORADO; PUBLIC SERVICE COMMISSION OF WYOMING; COLORADO-WYOMING GAS COMPANY; PUBLIC SERVICE COMPANY OF COLORADO; and COLORADO INTERSTATE GAS COMPANY, RESPONDENTS.

ON PETITION TO REVIEW AND SET ASIDE ORDERS OF THE FEDERAL POWER COMMISSION.

FILED SEPTEMBER 9, 1942.

VOLUME 7—Pages 3671-4350

Witness HAMMER further testified on cross examination, Vol. 54, pp. 7507-7593, inclusive, as follows:

The pressure contour (Isobar Map 179) follows the outlines of the field, with some minor exceptions, as determined by the Texas Railroad Commission, the total distance from one end of the field to the other being approximately 120 miles. The outline of the field was not determined by the witness but he merely copied the outline as determiined by the Texas Railroad Commission, with some minor exceptions.

Beginning at a point just southwest of the town of Pampa right near the southwestern limits of the town, a dotted line is shown which runs generally from that point to the northwest through the remaining portion of Gray County across Carson County and through the more or less central portion of Hutchinson County. This dotted line (Exhibit 179) represents the northeastern limits of the productive gas territory or the outer limits of the gas field in this particular area as interpreted by the Texas Railroad Commission.

The area between the dotted line above referred to, and the outer heavy solid line in the same area, represents oil producing territory. There are some dry spots but generally the structures are favorable for oil production. The little dots between the dotted line and the outer heavy line represent producing oil wells, each dot representing a well, but he did not know the approximate volume of oil production in the field as of the time of testifying.

There is another dotted line generally south and southwest of the dotted line above referred to on the pressure contour map (Exhibit 179). This dotted line begins just south of the town of Pampa in Gray County and runs generally from that point in a northwesterly direction in a rather irregular wavy line across the north portion of Gray County, entirely across Carson County and intersecting the Carson-Hutchinson county line some ten miles east of the northwest corner of Carson County. The line continues across the southwestern portion of Hutchinson County and intersects the Hutchinson-Moore County line at a point probably 12 miles north of the southwest corner of Hutchinson County. It continues across Moore County and northwesterly to a point some 6 or 7 miles east of the town of Dumas in Moore County, thence in a general southwesterly and

southerly direction across the town site of Dumas, thence a little to the southeast and then turning back again southwesterly to a point where it intersects the Moore County and Hartley County Line about 5 miles north of the southwest corner of Moore County; thence, a curved line from that point extending somewhat into Hartley County and then turning back southeasterly again and then generally in a southerly direction to a point of intersection with the southern limits of the field near the northwest corner of Potter County. This line represents the division point between the sour gas producing area and the sweet gas producing area.

Sour gas contains sulphur and/or hydrogen sulphide in quantities too great to make such gas desirable for domestic use, while sweet gas is comparatively free from such substances. Otherwise the two gases are practically the same.

The sweet-sour gas line was not located by the witness but was taken from maps prepared by the Texas Railroad Commission.

Sour gas is produced north and northeast of the line and sweet gas, south and southwest of the line, except at the western edge of the field where the sour gas is produced generally west of the line, and sweet gas east of the line.

Again referring to the little dots on the pressure contour map included in the gas producing area, beginning in Wheeler County near the south-central portion of the County and running pretty well along the northeastward portion of the gas field, across Wheeler, Gray and Carson Counties, and well into Hutchinson County, all of which are in the gas producing area, such dots generally represent oil wells, all of which have been drilled in the gas producing area and through the gas producing horizon before they encountered oil. This portion of the gas field also produces oil and has produced large volumes of oil. The structural conditions are such, however, that in drilling for oil they have drilled through gas-producing formations, the oil lying just underneath the gas, in a separate strata.

The discovery well in the entire panhandle field was drilled in about 1918 or 1919 on the Masterson Ranch in Potter County, and on acreage that the witness thinks is now owned by Canadian River Gas Company. This well,

the witness has been told, was just a wild-cat well. Other wells were drilled at a later date in Potter County. The nearest known production of oil or gas at the time this well was drilled was in the vicinity of Vernon, Texas, or somewhat east of Vernon, around Iowa Park, Texas, the distance being probably 200 miles from the Masterson Ranch well. After the Masterson well was drilled there were other wells drilled in an effort to find oil. There was a great deal of drilling but for the first several years after the discovery well the most of the wells drilled were gas wells, and although such wells were drilled for oil, the operators were successful only in developing gas.

The witness further testified (Vol. 54, p. 7524) as follows:

Q. Was there any market for the gas at that time, do you know, Mr. Hammer?

A. Well, there was a market but there wasn't any outlet.

Q. All right; we'll say that?

A. No, there wasn't any at that time.

The first oil well was drilled in the Texas Panhandle Field in about 1925, although oil might have been discovered somewhat earlier than that date. The big production of oil in the field began with the discovery of the Borger field in the latter part of 1925, or the first part of 1926. The presence of oil was probably known to some degree in the latter part of 1925, but the big drilling campaign commenced in 1926.

Borger is in the southern part of Hutchinson County. The various little dots shown on the isobar contour map (Exhibit 179) to the eastward and to the northeastward, to the north and to the northwest of Borger, might be termed the original Borger oil pool which became very active in 1926. All of the wells around Borger, between Borger and the dotted line which represents the outer limits of gas production, were drilled for oil, and generally all of them produced oil, but I think those wells were drilled through the gas producing formation. Very little attention was given to saving and utilizing gas production at that time. A great deal of gas was blown into the air. Later gasoline plants were erected and a small volume of natural gasoline was extracted from the natural gas and the residue was blown into the air. Residue gas is the gas that remains after the gasoline

has been extracted, and you have almost as great a volume of gas after the extraction of the gasoline as you had before. All of this residue gas was blown into the atmosphere.

Following the discovery of the Borger pool wells were drilled in and around that general area, the wells generally being southeastward from Borger along the northeastern portion of the structure, down to Pampa and the little town of Lefors in Gray County and on down into the northern portion of Wheeler County. Many of the wells, although drilled for oil, discovered gas only. If they were drilled a little too high on the structure to produce oil, they almost certainly encountered gas. A great many of the old gas wells that were drilled primarily for oil in the first instance were disappointments since no oil was discovered, but they did encounter gas and the wells were saved as gas wells.

Many of the oil wells produced both oil and gas. All of the little dots shown on the Map (Exhibit 179), but within the gas producing area, also encountered gas, or at least the greater majority of them did. There might be some exceptions to this but generally they all did discover gas. It is a very rare thing to get a dry hole within the gas producing area so far as gas in concerned. Each of the wells represented by the little dots above referred to encountered gas even though the wells might also have encountered oil, unless the well represented a dry hole in both cases.

There were a great many gasoline plants constructed in the early days of the Texas Panhandle Field to utilize gas for the manufacture of natural gasoline. During that period this field became noted as one of the largest natural gasoline producing areas in the world. Plants were constructed pretty well along the entire northeastward border of the field from Wheeler County to Hutchinson County and later on up into the northern portion of Moore County. The witness did not observe the practice of completing oil wells during that period, but did learn from his general investigation, and in discussing the matter with operators in the field, that well owners did sometimes cement the inner casing improperly, or after cementing it jar it loose or perforate it in some other way in order to get a much larger gas production from the gas producing strata above the oil strata. Witness stated that he had heard this practice be-

came the scandal of the industry for a while, and he had heard it said that there were great volumes of dry gas or natural gas produced with the innercasing string and then processed for its natural gasoline. The witness assumed that all of the gas in the Texas Panhandle Field, whether it is produced in the oil field section or high on the structure or wherever it is produced, does have sufficient gasoline content to make it profitable to remove the natural gasoline. It is a uniform practice at any rate to remove the natural gasoline from such gas, and if it were not profitable Canadian River would not be taking it out.

After the natural gasoline plants were constructed carbon black plants were constructed in the field to utilize the residue gas from the gasoline plants. The carbon black plants were generally constructed near the gasoline plants. Plants were constructed in the northern part of Parsons County around Whitedeer, around Pampa and in Wheeler County, in Moore County and around Borger. A great deal of the gas produced in the field was not utilized for fuel but was blown into the air or burned in carbon black plants. The witness does not know the total volume of gas used in the manufacture of carbon black but he would not be surprised if more than 90% of all of the carbon black in the world is made in the Texas Panhandle.

Carbon black is made simply by burning the gas against an iron. It is burned under low or insufficient air conditions so that it will produce what is ordinarily called a smoke or soot. The soot collects on the angle iron and a moving chain with scrapers removes it. Carbon black is just the soot from the burning of gas against a steel plate somewhat like the smoke off of a lamp chimney. It takes around 1,000 cu. ft. of gas to make a pound of carbon black. Carbon black is used largely in the production of automobile tires and prolongs the wear and tear on tires—it toughens the tire. Before the days of carbon black, zinc oxide was used for that purpose, but did not give nearly as much mileage on the tires as carbon black.

The next step in the evolution of the gas industry in the Texas Panhandle Field was the construction of stripping plants. This period began along in 1933 or 1934, after the Legislature of Texas had enacted a statute which permitted operators to utilize gas from gas wells, that is, just natural

gas as produced from the wells and extracted the gasoline from the gas and vent the residue into the air. The witness recalls that there were several such plants constructed and great volumes of gas during that period were popped (vented) into the air.

Still later the Legislature of Texas enacted a statute permitting the manufacture of carbon black from sour gas. The carbon black industry was greatly expanded subsequent to that time although there had been carbon black plants in the field prior to that time utilizing the so-called casing head gas, that is, gas produced with the inner string of casing, but which frequently, by reason of improper well completions, came from the gas producing stratum above, that is, from the gas producing portion of the structure.

Sour gas is produced north and northeast and in the western part of the field to the west of the sour gas line hereinabove referred to, and the wells located in that portion of the field produce sour gas. This gas is run into gasoline plants and the residue is burned as carbon black.

The witness has not particularly traced the history of the carbon black plants, and in getting his production figures did not attempt to determine the volume that was consumed by carbon black plants. He attempted to go back of 1935 in his production studies, but decided that the data prior to 1935 was not complete although the Texas Railroad Commission had compiled production figures prior to that date, but the gas was reported on different pressure bases.

The witness further testified as follows (Vol. 54, pp. 7555-7561):

Q. We are just about through, Mr. Hammer, with some of this historical background. I believe we were on the matter of the legislation of the State of Texas which permitted the use of certain types of gas for carbon black, were we not, when the recess occurred?

A. Yes, I think we were.

Q. Now, your study of the history of the field and particularly the production history of the field, has indicated to you just what has happened since that legislation was passed, has it not, Mr. Hammer?

A. When was the legislation passed?

Q. It was passed in 1935.

A. That is the statute you are talking about, the 1935 statute?

Q. Yes. It is ordinarily referred to as "House Bill 266," almost universally so. You will see in the Railroad Commission's report that it is listed as "House Bill 266."

A. I think in general that my study has covered that period from 1935 on.

Q. Now, prior to that time you had noted no doubt that the gas that was utilized by carbon black plants was produced generally in the Borger area and I might say also in the Sanford area just west of Borger. Do you know what I mean by the Sanford area?

A. As I stated a while ago, I haven't traced the history of where carbon black plants were located.

Q. In getting your production figures which show the outlet for the gas or the disposition of the gas, it shows certain portions of the gas for carbon black plants, doesn't it?

A. You are referring to the time prior to 1935?

Q. Yes, from the beginning to almost 1939.

A. Well, from 1935 on we took notice of that phase of it, yes.

Q. Well, didn't you go back of 1935 at all in your production studies?

A. Yes, we attempted to go back of 1935 but if you will recall in my written statement—I said that just because of this thing we are talking about now—that I didn't consider the data prior to the time of such characterization that it could be utilized with any degree of accuracy.

Q. But you necessarily had to go back of that before you could determine that in your mind it was not satisfactory for your use?

A. I did go back of that.

Q. So you had to go back of 1935 in your study of the field and the producing history of the field?

A. That was after I had found out that the history was up to a certain point prior to 1935 and then decided to make my study on the area from 1935—at times from 1935 on, I did not give that early period very much attention.

Q. What was the difficulty, Mr. Hammer, with those earlier records which you discarded in your study of the matter?

A. Well, I think I have stated that fairly well in my written statement.

Q. You said it was black-out. It wasn't hardly that bad?

A. All right.

Q. The Railroad Commission of Texas has compiled—

A. We couldn't depend upon the early pressure that was recorded. The various bases at which gas was reported to the Texas Railroad Commission varied over such a wide range, and as a matter of fact, the Texas Railroad Commission itself has no information that can be relied upon as to what pressure was utilized in those early reports turned into the Commission.

Q. That is quite true. I say, that is quite true, but I don't know whether I mean to say just that, but I do mean to say that the Commission prior to 1935 did not require gas to be reported on a uniform pressure basis?

A. That is right.

Q. And that is as far as that statement can go, isn't it? They did require the reports?

A. They did require the reports.

Q. The production reports?

A. The production reports, but they didn't—

Q. Some operator might operate on some pressure that was one and some other—

A. That is right.

Q. And that is the extent of your criticism, isn't it?

A. That is one of them.

Mr. March: Please let the witness finish, Mr. Keffer.

Mr. Keffer: I beg your pardon. I thought he had.

The Witness: I made an attempt to get at the early history of those early pressures—those early pressure bases, and I wasn't very successful.

By Mr. Keffer:

Q. As a matter of fact, the Railroad Commission of Texas does carry in its records the annual volumes of gas production in the Panhandle and as the official regulatory body of the state of Texas does rely upon those records, is that not a fair statement?

A. Well, there are various degrees—

Mr. March: We object to the question. We don't object to the rewording of the question, but to have this witness to say what the Railroad Commission of Texas relies upon,

Mr. Examiner, isn't a proper question. He can reframe the question.

Mr. Keffer: Suppose you ask the question.

Mr. March: I am not interested in getting an answer but I am interested in seeing that this witness is not put in the position of testifying as to what the Railroad Commission of Texas relies upon.

By Mr. Keffer:

Q. You can say if you don't know, Mr. Hammer. You went through the Railroad Commission's records at Austin, Texas, did you not?

A. That is right.

Q. And you got certain data from those records?

A. That is right.

Q. And so far as you know, the Railroad Commission does rely upon the records which they keep and have in their possession with respect to this gas production?

Mr. March: I object—

Mr. Keffer: I said, as far as he knows.

Mr. March: As far as the Commission's counsel is concerned he is not going to permit the witness to answer unless the Examiner so rules, because any construction this witness can put on what the Railroad Commission relies upon or any Commission relies upon is a construction or question that can be answered either way by the witness. He shouldn't be required to answer it. He could say he didn't know, of course, but it is an improper question and we don't propose to stand idly by and see an improper question answered.

Mr. Lange: Too, Mr. Examiner, even if he stated he knew or thought he knew, he couldn't read the minds of the Texas Railroad Commission to determine what they had in mind.

The Trial Examiner: I think that is right, Mr. Lange.

When you use the term "rely," Mr. Keffer, by that you mean that is the only official record, the official record that the Railroad Commission has of the production in the field?

Mr. Keffer: That is exactly what I mean, that the Railroad Commission's orders are of course official records, it being an official body.

Mr. March: He can ask whether he knows as to those records being on file with the Railroad Commission of Texas. He can ask that question and he can state whether they are filed, but to say as to whether this Commission relies upon those records generally or in any specific case, that is a matter not for this witness to testify to.

Mr. Keffer: It doesn't make any difference in particular.

I believe, Mr. Examiner, that they do rely upon those records.

The Trial Examiner: I would think so, Mr. Keffer, assuming they are the only records they have. However, I think the argument of Commission's counsel is sound.

Mr. Keffer: I think that is probably correct.

Q. I might have asked you the question, but to be certain, I will state it again anyway.

The Railroad Commission of Texas does keep records prior or does have records showing the production of gas from the Panhandle field prior to 1935?

A. Yes, they do. I might add to that that we found in the Commission's early records in Austin, Texas; that they were very incomplete; that there were a lot of people in the early days who produced gas but didn't turn in any reports.

Q. You have no idea as to the relationship or as to the percentage, rather, of reported gas and unreported gas?

A. No.

The witness made no distinction between sour gas production and sweet gas production in his studies and made no segregation as between carbon black plants or other uses, although he did consider the total volume of production from 1935 to 1939 without regard to the uses of the gas produced. He was not interested in the segregation of the figures after the gas came out of the ground. He gave no consideration to the volume of sweet gas that was produced because, according to his viewpoint, he didn't think in terms of sweet or sour gas, but he was interested in getting the volume of gas that came out of the ground. Although he spent some time in the field he did not inspect any of the carbon black plants. He saw them but he didn't pay any particular attention to them. It didn't make any difference

to him what became of the gas after it was produced and it didn't require any knowledge of the carbon black plants or their locations, or the volumes consumed by them. He didn't use judgment factors to any great extent, but his work was based as nearly as it could be on the actual factual data. There might be some slight variation from this, but not very much. He used his judgment to some extent, but not a great deal. The only factor he needed was the volume of gas that came out of the ground and the disposition of it made no difference, or whether it was sweet or sour gas, or whether it came from the sweet gas area or the sour gas area.

In every one of the areas (quadrants) the witness considered all of the gas that came out of all of the wells and every quadrant in the field as nearly as he could get it, and then utilized that information in that particular area regardless of any disposition of gas after it was metered from the well. He stated, for example, that when he considered the reserve estimate of quadrant 2 in Hutchinson County, which includes Borger, he was not particularly interested with the gas that came from east of Borger where so many wells have been drilled, or whether it came from the southwestern portion of the quadrant, or whether it came from the northern part of the quadrant. It made no difference whatsoever in so far as the witness was concerned.

Witness knew there had been an increase in gas production in Moore County since 1935, but he didn't know whether there was a slight increase or a large increase until he had a chance to check it. He didn't think there was any production, relatively speaking, in the sour gas area of Moore County prior to 1935. He knew there had been a large production of sour gas in Moore County beginning with 1936, but didn't know the volume and didn't know whether it produces more than one-half of the sour gas in the entire field or not. He did not know from memory how many carbon black plants there were in Moore County, and neither did he know the number of casinghead plants—natural gasoline plants—without checking. He did not know whether there were any pipe lines leading out of northern Moore County to the Borger and Sanford area in Hutchinson County which transported sour gas to carbon black plants, but thought there was one line that transported sour gas to gasoline plants.

The natural gas development in the Panhandle, with respect to pipe lines, began in about 1928. The pipe lines take their gas from sweet gas lines, and practically speaking, there is no sour gas used in the pipe lines except for a small portion in Hartley County, and perhaps isolated cases over the field along the sour-sweet gas line. The pipe line companies are taking sweet gas almost exclusively from the sweet gas area.

The witness did not know the comparative volume of gas produced from the field that actually goes into the pipe line leading out of the field as compared to the total production of the field. He made no study of that at all. The witness paid no attention whatsoever to gas that was lost in drilling operations because it was virtually impossible to get it and he would have to rely on somebody's judgment since such gas was not metered.

The witness went into the field a number of times and discussed all sorts of matters with various field superintendents, and in many cases the opinions were checked against the records but he couldn't; at the time of testifying, be more specific as to just what information he gained from them. The witness then stated that it was very difficult to make an estimate of gas reserves in the Texas Panhandle Field, or in any other field, without having a rather intimate knowledge of the field, and that it takes time to do this and that you get part of the information from the people that live and work in the field, and the rest of it is personal observations made by going through the field.

The witness further testified (Vol. 54, pp. 7586-7591) as follows:

Q. Just how many trips did you make through the field, Mr. Hammer, approximately? Give it to me approximately, if you haven't it exactly.

A. I don't know as I could give you that exactly. Oh, it was probably ten or fifteen, something like that.

Q. What did you do when you would go out on these trips?

A. We would try to find, usually the field superintendent of these various companies producing gas.

Q. What would you do when you found him?

A. We would ask him all sorts of questions trying to get

facts and opinions from people that we thought should have a worth-while opinion.

Q. Did you then check those opinions against records?

A. In most instances we checked a lot of those opinions, yes.

Q. What was the occasion of having these opinions if by scientific process you can take a slide rule and figure it all out?

A. Well, I will change that. I will say experience of these superintendents.

Q. What do you mean by experience? What does that include?

A. Well, that includes their operating experience in the production and drilling and care of gas wells, things of that type.

Q. That is still rather general. Can you be more specific on just what information you gained from them?

A. Not right at the present time.

Q. You knew at the time how gas wells are operated, pretty well, didn't you?

A. Well, various superintendents had various ideas of how to do this thing and how to do the other thing. They don't all have the same ideas, and what we were after was—

Q. Did that help you, then, to formulate an opinion as to the reserves in the field after talking to those people?

A. It helped to give us certain facts or where we could find certain facts.

Q. In other words, to get back to this fundamental thing, it is difficult to make an estimate of gas reserves in this field or any other field without having a rather intimate knowledge of the field, is that not correct?

A. You must get a rather intimate knowledge.

Q. It takes time to do that—you get that from the people that live in the field and work there. Is that a fair statement?

A. Well, that's part of it.

Q. What's the rest of it?

A. Well, the rest of it is observation personally that I got from the field in going through it.

Q. That's right. I appreciate that, that you do get knowledge that way that is of substantial benefit in the kind of work in which you were engaged, but now can you detail

just a little more the observations that you did make in that connection?

A. Well, I'll tell you the particular thing, among other things, the particular thing we wanted to find out in talking particularly to the superintendents was such things as the condition of the wells, where the condition of wells had any effect on the pressure and volumes of the wells, or whether there were any water effect in the well in different localities; whether wells had been drilled too deep, for example, and had gone into water, and where they had drilled down into the granite wash, and what the effects of these things of that kind were.

Q. Now, did you ask them about the actual drilling of the wells, the type of formations encountered and matters of that sort; where they encountered them?

A. Oh, we discussed that, I think as a sort of a side issue because we had most of the logs on the wells.

Q. You relied on the logs very largely to give you that type of information?

A. Yes. There were too many wells to do anything else with.

Q. As to the development and as to producing formation and so on?

A. Well, we discussed the reservoir conditions with some of them, certainly, because that was a problem.

Q. Did you examine any well cuttings?

A. It wouldn't have done me any good if I had.

Q. Why?

Mr. Spencer: The question was, "did you?"

The Witness: No, I didn't, and I repeat again it wouldn't have done me any good if I had.

By Mr. Keffer:

Q. Wouldn't have meant any more to you than if I had gone out and done that?

A. That's right, or anyone else, for that matter.

Mr. Keffer: Mr. Examiner, it is a little past 4:30 and it might save a little time if I could get some of the rest of my examination a little better in mind.

If the Examiner would like for me to blunder on through, I can, but I think—

The Trial Examiner: Well, I don't want to force you to go ahead, Mr. Keffer, if you feel—

Mr. Keffer: I feel it would be advantageous to me, but certainly to the Examiner, and I think maybe to the attorneys and maybe even to the witness.

The Witness: May I make a statement?

Mr. Keffer: Yes.

The Witness: I said I hadn't examined any of them. I want to qualify that this way.

Mr. Spencer: Any what?

The Witness: Any of the nut cuttings. I didn't examine any cuttings but I did examine a considerable number of cores that were taken from the field, that were taken out in the early days before they started using cable tools for finishing the well.

By Mr. Keffer:

Q. Did you examine any late cores?
A. I don't think they have taken any recently.

Mr. March: Mr. Hammer, you went through the field just for your general information?

The Witness: That is right.

Mr. March: You didn't collect this basic data for this exhibit by going around talking to somebody and considering what he said the cuttings were, and so forth, or hearsay like that?

The Witness: I paid no attention to anything like that.

Mr. Keffer: I want to interpose an objection to counsel leading his witness, and I think that objection has good foundation.

Mr. Hammer continued his testimony as shown by Vol. 55, pp. 7598-7782, inclusive, as follows:

Q. Mr. Hammer, did you make an effort to secure information that Mr. Keffer requested regarding the utilization of gas for carbon black purposes?
A. Yes, I did.

Q. With what result? Were you able to secure the yearly production?

A. The annual reports of the Texas Railroad Commission give that information by daily averages by months. I found in none of them a total figure, and in each year, of course, the only report was for the first seven months of the year, so that in order to get a total for the year, taking daily averages by months, it would require an enormous amount of work.

Now, in lieu of that, I got some information that I think will fill the requirement and give what counsel wants as well as giving the total figures.

Q. Will you read that into the record?

A. These excerpts that I will read are verbatim quotations from the actual report of the Texas Railroad Commission for the years 1938 and 1939.

The first quotation is on Page 18 of the 1938 Commission report: "Of the total gas produced in the field and utilized during the first seven months of this year, 37.4 per cent was taken by pipe lines for light and fuel distribution; 45 per cent was burned in carbon black plants * * * "

Cross Examination

By Mr. Keffer:

Q. How much?

A. 45 per cent.

" * * * 2.3 per cent was vented into the air from gasoline plants; 11.6 per cent was consumed as plant and lease fuel and 3.7 per cent was accounted for as extraction loss in the removal of gasoline content."

That is for 1938.

Q. That is for the first seven months in 1938?

A. In the first seven months.

In 1939—the first quotation is on Page 9 of the 1939 Texas Railroad Commission's report: "Casing head production continued its decline, falling about fifteen billion feet for the year, or approximately 12½ per cent. The amount of sour gas withdrawn decreased roughly sixteen billion feet from the last year's total."

On Page 11 of the 1939 annual report—

Q. Was that 1937 or 1939 you have just been reading from?

A. 1939.

Q. 1939?

A. Yes. "The total gas produced in the field and utilized during the first seven months of this year, 40.31 per cent was taken by pipe lines for light and fuel distribution; 45.76 was burned in carbon black plants; 1.55 per cent was vented into the air from gasoline plants; 8.92 per cent was consumed at the plant as lease fuel and 3.46 per cent was accounted for as extraction loss through the removal of gasoline content."

Mr. March: Mr. Hammer, did you utilize any of that data in the preparation of this exhibit?

The Witness: No, I did not.

Mr. March: I wish to state we are furnishing this information because we want to cooperate with you, Mr. Keffer, but this has nothing whatsoever to do with the exhibit and if you want any further information regarding the disposition of the gas produced in the field, you will have to put it in by one of your own witnesses. I want to get the record clear in that regard.

The witness made no use of this data in the preparation of his Exhibits 179 and 180. He considered the geology of the field only in a general way. His study of the character of the field dealt largely with the characteristics of the producing horizon itself. The producing formations are dolomites and limestones, but the greater part of the producing formations are dolomites. There is some granite wash, but it has relatively little importance, and it is his opinion that it would be better practice not to even try to recover the gas in the granite wash until the field is more nearly exhausted from the upper horizon. The most prolific gas producing areas in the field are in part of Carson County and the northwest part of Moore County which follow a line close to the axis of the fold, and he means by "axis" the highest structural point which would be somewhat south of the exact center of the field.

The witness further testified (Vol. 55, pp. 7605-7606) as follows:

Q. What do you mean "axis"?

A. The highest structural point.

Q. In order that we might visualize that a little greater, would you say that the axis, generally speaking, would represent a line just about dividing the field into two equal parts?

A. No.

Q. Give me a little more definite description of what you mean by axis.

A. It would be somewhat south of the exact center. It is difficult to describe it.

Q. I appreciate that. I would like to have you just as nearly as you can give a general statement that the Examiner and others here might hear in order that they might visualize pretty well what you mean by that.

A. Well, in general—this is just a broad explanation—

Q. I understand that.

A. The axis of the fold would start in some place in the vicinity of Quadrant 3, Moore County; it would cut across Quadrant 2, and the southwest corner of Quadrant 1, Moore County; the northeast corner of Quadrant 1, Potter County; and through about the center part of Quadrants 3 and 4, Carson County; and just north of the town of Whitedeer, or in the vicinity of Whitedeer—

Mr. Lange: What county?

The Witness: Carson County.

Then it would hit into Quadrant 4 of Gray County; thence from there in a southeast direction through Quadrant 5, Gray County; Quadran 4, Gray County; Quadrant 3 in Wheeler County, and Quadrant 2 and 1 in Wheeler County.

Mr. Lange: That is Quadrant 6, Gray County?

The Witness: That is right.

By Mr. Keffer:

Q. To state it a little differently, that is generally a line a little south of what you might call the center line from the northwest to the southeast?

A. In the western part of the field it would be considered south.

He determined that these areas were the most prolific by taking the total production for each quadrant and determining the per-acre pound decline. He examined some 700 or 800 gas well logs, but could not name them, did not keep a list of them, and did not record the data. He examined the well logs to see if the dolomite had been penetrated and to determine the physical condition of the well, but made no notes. He determined the total thickness of pay formation by taking the entire measurement of the dolomite penetrated whether it was productive of gas or not. He determined areas of low productivity and determined where the low production per-acre pound decline was located.

The witness stated that beginning with the bulging point on the south side of the field just south of Whitedeer in Carson County and east of this over into Gray County, and on through over to the eastern end of the field, you will find an area of low productivity and has no particular significance with respect to the producing ability of the field. It is an area of low productivity. He has determined that this is an area of low productivity by a study of the acre-pound decline. There has been quite a lot of production from the area just referred to in Wheeler County. The pressures in much of the area are high—above 420 pounds. The production has been slack. He found the productivity of the area along the limits of production, along the south side and southwest side of the field, to be variable in Potter and Carson Counties. Although his quadrant took in this acreage with other more productive acreage, it does not clearly show the extent of the productivity along the edges. He did not study the edges of the field particularly as to productivity in Carson and Potter Counties except as to the extent reflected by his quadrant as a whole.

In determining his weighted average pressures as a basis for his reserve estimates, he procured the weighted pressures from the weighted average areal pressure although he did not compute the acre content for the area between each isobar line, but only considered this area in determining his average pressures, then considered the entire acreage and the entire production in a quadrant in arriving at the per-acre pound decline in pressure. In other words, he first laid off the isobars, then laid out quadrants. He used a plani-

meter and determined the area in each quadrant between each isobar line. He then determined the area for the entire quadrant. He then took the area between the isobars and multiplied that by the average pressure between the isobars. Then he took the summation of all these and divided that by the total acreage and arrived at an average weighted pressure for the quadrant. This was illustrated by taking Quadrant 1 in Potter County. The isobar lines on the south line of the Quadrant indicated a pressure of 430 pounds. He had the pressure and the acreage in the 430 pound pressure segment and the production, but he did not attempt to determine the productivity between the isobar lines. He simply determined the weighted pressure and the weighted productivity for the entire quadrant. He made no effort to determine production or productivity segment by segment because it wasn't necessary in his opinion. He did not think he would have gotten any better answers if he had determined the volume of gas in place per acre between each isobar line and didn't know whether the Texas Railroad Commission approached the problem this way or not because they have never put out any estimate of reserves.

He then stated, with respect to the illustrative Quadrant, that he averaged the whole thing in from the north line of the county to the southern limits of production (Quadrant 1, Potter County). He didn't figure each segment separately, and that was true of each segment and of every Quadrant through out the field.

The witness further testified (Vol. 55, pp. 7631-7636) as follows:

Q. I take it from the statements you have just made in answer to preceding questions, Mr. Hammer, that you found no wells in the field that contained 200 feet of dolomite which produced gas all the way through the entire thickness of the dolomitic formation encountered?

A. Well, I understand your question now. I didn't before. I think it is a true statement that at least the logs don't show production all the way through.

Q. Do you have any better evidence than the logs on those things?

A. No.

Q. That's right. So, so far as you know there are none?

A. Are none what?

Q. Are no wells with 200 feet of producing thickness of dolomite.

A. As far as I know I would say there were none.

Q. That's right, and you have no reason to suspect that there are some with that much producing thickness?

A. Well, I think it would be a fair statement, although I think there is some confusion in the interpretation of a lot of things in connection with those wells in this respect:

You will notice on a log that it says an increase at such and such a point on the log—an increasing flow. As a matter of fact, it is difficult to tell exactly when an increase does start when you are drilling a well. You might have a slight increase in drilling down and suppose you only attempted to gauge an open flow well, say, every ten, fifteen or twenty feet in drilling. Well, you might have a slight increase all the way down, then when you gauged you might show a total increase. Well, if the formation happened to soften up a little bit right at the time you made your test you wouldn't be justified in saying that all that gas came out of that particular point, see?—because some of it might have come from above. There is more or less porosity throughout the entire thickness of the dolomite and naturally even the smaller—the parts of smaller porosity naturally contain some gas.

Q. All right, now, what investigation have you made to determine all those things you have been talking about?

A. I didn't make any investigation of porosity.

Q. You are just theorizing now?

A. No, it is based on knowledge after having been around dolomitic and limestone oil and gas fields for many years. That is a judgment.

Q. That is one thing you can't work out on a slide rule?

A. That is right.

Mr. March: May I interpose a question?

Mr. Keffer: Please answer the question first.

The Witness: Didn't I answer it?

The Trial Examiner: There is no question pending, Mr. Keffer.

Mr. Keffer: Go ahead, Mr. March.

Mr. March: You did not—

Mr. Keffer: Don't ask a leading question.

Mr. March: Maybe it will be best that I not ask a question. I will wait until redirect and take up the points.

Mr. Keffer: All right.

Mr. March: I didn't intend to ask a leading question.

The Trial Examiner: Were you going to clear up an uncertain point here in this testimony?

Mr. March: That's right. If this is not satisfactory, we can strike it, Mr. Keffer.

Mr. Hammer, when you were giving that average of 200 feet a few minutes ago, you did not intend—you were merely giving the average depth of the dolomite, were you not? You were not giving the average depth of the producing formation?

The Witness: That's right, the overall figures of the total thickness of the dolomite.

Mr. March: Did you use in any manner in this exhibit the thickness of the dolomite in the producing formations?

The Witness: No.

Mr. March: In the computation of your reserves by the pressure decline method?

The Witness: I did not use them at all.

Mr. March: That's all.

By Mr. Keffer:

Q. All right, now, as a matter of fact, Mr. Hammer, it all resolves itself into just this, doesn't it, that you weren't particularly interested with the thickness of producing formations; therefore, you made no specific effect to determine the producing thickness of producing formations?

A. Now, I will qualify that.

Q. Can you answer yes or no?

A. I can't answer yes or no and I won't answer it yes or no. I will answer it in my own way.

The Trial Examiner: Answer it, Mr. Hammer. You don't have to answer yes or no. You can answer in your own way, but try and respond to the question.

The Witness: What is the question?

(The question referred to was read by the reporter, as set forth above.)

The Witness: All right, I'll answer it this way: As I stated before, the only thing I was interested in was total penetration of the producing dolomite regardless of the so-called thickness of pay strings. I wanted the total penetration to find out—

By Mr. Keffer:

Q. You wanted the total penetration to see whether the open flow of the well was truly reflected, is that correct?

A. I wanted to see whether all of the thickness that could possibly produce gas had been penetrated.

Q. That's right, in order that you might know that there weren't some producing formations that were left that were not uncovered?

A. That is correct.

Q. All right, then, from the standpoint of making your reserve estimate, you cared nothing about the producing thickness in so far as reserve figures were concerned and paid no attention to them?

A. Well, now, let me get this straight: What do you mean by "producing thickness"?

Q. The actual number of feet that actually produced gas in any given well.

A. I maintain there is nobody that can determine that.

Q. Suppose there are people that say they can determine it?

A. All right, let them prove it.

Q. You aren't in position to prove it?

A. It is not necessary to attempt it.

Q. I know, but, now, if you will bear this in mind, Mr. Hammer, it will help this a lot. You have some rather definite ideas and you are pretty steadfast, apparently, on them. There may be other geologists that have other different ideas.

A. All right.

Q. We want to explore this thing fairly, fully and accurately. When I ask you a question, when you don't think it makes any difference, I wish you would answer the question anyway and we will get along a lot faster. Will you make that agreement with me on that?

A. Well, as far as possible.

The witness saw various wells drilled in between the years 1926, 1927 and 1928 when he was in the field, although he had not seen any drilled in recently, but he knew how they acted and how they looked when they were drilled in. He thought it was a very foolish requirement for the operating companies to require their geologists to observe wells drilled in. Although it is customary for companies to require their geologists to be present on the derrick floor when a well is being drilled through the producing formations, he still thinks this is a foolish requirement because he can get all that information from the well log of the average well and there would be no reason for being present. He does not believe that you can get an accurate determination of the porosity by examining well cuttings from gas wells in the Panhandle Field, or any where else, and he did not attempt to do it.

The witness further testified as follows (Vol. 55, pp. 7639-7644):

Q. All right, now, Mr. Hammer, again, have you ever known—I will state it that way—of gas reserves having been estimated by the porosity sand thickness method?

A. Yes, I have known of it.

Q. Do you think those estimates are of any value?

A. It all depends on conditions under which the estimates are made and the character of the producing horizon.

Q. Now, what are those conditions?

A. Well, you take sandstone condition, where your sandstone has not undergone any change, where it is not attacked by weak acids that might be in any gas or water, and if you have good cores, taken by the core barrel from the sandstone, you can arrive at a very definite—I think at least a fair estimate of gas reserves.

Q. Isn't it difficult to get good cores in a gas well?

A. It is almost impossible.

Q. That's right, so that you just take the whole thing out when you base it on good cores, don't you?

A. Yes. You mean as far as a dolomite—as far as the Panhandle is concerned?

Q. As far as any field is concerned.

A. If you can't get good cores?

Q. Yes, that's right.

A. I think that is in general a fair statement, if you want to get an accurate estimate.

Q. Well, we will just agree that you can't get good cores, generally speaking, in a gas producing formation.

A. In the Panhandle?

Q. Or anywhere else.

A. Oh, yes.

Q. Well, where do you get them?

A. Where?

Q. Yes.

The Trial Examiner: You mean what other field, Mr. Keffer?

Mr. Keffer: Yes, that's right.

The Witness: Well, I don't recall exactly now. I know of gas producing horizons where cores have been taken in the gas producing horizon.

By Mr. Keffer:

Q. What is the real reason why you can't get, ordinarily, a good core in gas producing formations?

Mr. Lange: You mean in the Panhandle?

Mr. Keffer: Anywhere.

Mr. Lange: Anywhere?

By Mr. Keffer:

Q. We'll say in the Panhandle. Maybe I should restrict it to that.

A. Yes, I don't like to—this is our problem right here.

Q. All right.

A. The reason is that—now, the question is, what are the reasons why you can't get a good core, is that right?

Q. That is right.

Mr. Lange: In the Panhandle.

The Witness: In the Panhandle.

By Mr. Keffer:

Q. That's right.

A. Well, apparently, the reasons are—I will qualify that somewhat. I mean that you can't get a good core through that part of the producing dolomite where it is indicated that a major flow of gas or oil comes from. You can get fairly good cores of some of the rest of the dolomite.

Q. That's right, but why is it you can't get a good core where the gas comes from the major flow?

A. Because the formation there is so soft and it has undergone perhaps so much solution in the past and attacked by different weak acids of different kinds. The only thing left perhaps is largely siliceous material that wouldn't be attacked by circulating waters or by weak acids, and when you attempt to get your core out all breaks down and goes all to pieces. You just can't get one out.

Q. Isn't that due primarily to the pressure of the gas?

A. No, I wouldn't say so because where you take a core with a rotary core barrel, the pressure exerted on that is by your fluid column; that is, by your mud column, tends almost entirely, if not entirely, to equalize your gas pressure so that it is just a question of the character of the material itself, is the reason why you can't get it out.

Q. Now, where you can't get good cores, what is the customary way for the determination of porosity?

A. I have never attempted to do it. I don't know.

Q. Do you know of any people that have attempted to do it?

A. I have heard of people that have, yes.

Q. How did they do it?

A. I don't know how they did it.

Q. As a matter of fact, can't you take your drill cuttings and examine them under a microscope and compare them with others of known porosity and by comparison arrive at a pretty accurate figure?

A. No, I don't think so.

Q. A lot of people do think they can.

A. Well, let them prove it.

Q. Well, now, as a matter of proving, you haven't proven

that it is not correct. Let's don't get into any argument about it.

A. Let me put it this way: I have yet to see any authority or any statement in any written literature where anybody has ever determined a method of determining the porosity of a dolomite or a limestone in place by the examination of the cuttings from that well.

Mr. Lange: In the Texas Panhandle field?

The Witness: Or any place else.

By Mr. Keffer:

Q. My question was, by comparing with certain cuttings of a similar formation concerning which the porosity is definitely known.

A. I don't think—

Q. Did you ever hear that?

A. I don't think it can be done.

Q. At least you are of the opinion that you can't do it?

A. I don't believe anyone else can.

Q. Well, now, you stated a while ago, I take it, that you can't utilize the porosity sand thickness method of determination of reserves in place in natural gas fields unless you have good cores of the area, is that right?

A. I think in general that would be—would approach, at least, a fair statement.

Q. You say "it would approach it." What is wrong with it?

A. Because of the horizontal variability in the dolomite itself. It varies so much from point to point that in order to get a fair average of porosity, even if you could take cores, you would have to drill more wells than would be ever economically or feasibly possible to drill in order to get a proper average.

Q. What is the variability in the Panhandle? You have referred to that two or three times.

A. Well, that's just the point. There are indicated variables there, but I don't know as anybody ever has been able to prove just what those variabilities are except in a general way. In other words, they are relative. They are a relative differential, not an actual.

Q. Don't you find that areas are rather uniform; that

the variability is between areas rather than between locations, from well to well?

A. No that rule won't hold.

The witness further testified as follows (Vol. 55, pp. 7646-7667):

Mr. March: Before we proceed further I wish to state I have secured the estimated reserves of the whole Texas Panhandle field and I wish to have it marked for identification.

The Trial Examiner: Very well.

Redirect Examination.

By Mr. March:

Q. I hand you what purports to be the remaining gas reserve in the Texas Panhandle field in Mcf. on a pressure base of 14.65 pounds per square inch absolute calculated to 25 pounds well head gauge abandonment pressure and I will ask you what it is.

A. Yes, that it what it is.

(Exhibit 186, Witness Hammer, marked for identification.)

By Mr. March:

Q. I will ask you if that estimate of the remaining gas reserves in the Texas Panhandle field was prepared by you or under your supervision?

A. It was. I assisted in it and it was prepared under my direction.

Q. I notice there that the tabulation does not contain a date. Is that as of August 1, 1939?

A. This is as of August 1, 1939.

Mr. March: Mr. Examiner, we might have that inserted on all of the copies.

The Trial Examiner: I think it would be advisable.

Mr. Spencer: Do you desire to have it inserted right under the title, Mr. March?

Mr. March: Yes.

The Trial Examiner: Yes, as of August 1, 1939.

By Mr. March:

Q. Since your cross examination has started and since you have offered your reserve of the Canadian River, you have consulted your working papers and data and have checked this estimate of remaining gas reserves, have you not?

A. Yes, sir, that is right.

Q. And it is your position that this has nothing whatsoever to do with the estimate of reserve for the Canadian River's acreage, although it does include the Canadian River's acreage reserve?

A. Except as to that part of it that lies in the territory where Canadian River has its acreage—

Q. It is your position it is independent and separate—

Mr. Spencer: Mr. March, let him state his position.

Mr. March: I have to ask him a question.

Mr. Spencer: Go ahead.

By Mr. March:

Q. Is it your position that the estimate of reserves for the entire field is not essential to your Exhibit 180 showing the estimated reserve of the Canadian River's acreage?

A. It definitely is not necessary.

Mr. March: Mr. Examiner, we offer this exhibit with the understanding that it is, as far as Commission's counsel is concerned, and that is as far as the purpose of the exhibit is concerned. We have not only gone one hundred per cent of the way with counsel here but we are now going two hundred per cent of the way.

The Trial Examiner: The Examiner may want to utilize Mr. Hammer's figures, too, Mr. March.

Mr. March: I think it would be the most accurate.

Of course, Mr. Examiner, this estimate of reserves of the whole field was not prepared in connection with this case. This estimate was in the Texoma case. We intended to offer that estimate in that case.

Mr. Spencer: When you get through there, Mr. March, you seem to be damning this with faint praise. If there

isn't any purpose for having it put in here; and you must remember that we haven't asked you to put it in here.

Mr. March: The cross examination is going to be over the whole field, so if we have to go through this ordeal we want to get the credit for having the reserve figure in.

Mr. Spencer. All right. It is in for the purpose of facilitating cross examination as far as you are concerned?

Mr. March: As far as I am concerned, it is an estimate of the reserve for the whole field.

The Trial Examiner: Let me straighten this out. I think perhaps the Examiner prior to the conclusion of this hearing may request just such information as has been placed in the record by Commission's counsel for whatever purpose the Examiner might want to use it for and I think with that understanding now in the record we may proceed.

Mr. March: I wish to ask this one further question:

Q. This estimate of reserves for the whole field was prepared in the same mannerism for the Canadian River's acreage as reflected in Exhibit 180?

A. The same method.

Q. The same procedure all the way through?

A. Yes, sir.

Mr. March: That is all.

The Trial Examiner: You may proceed now, Mr. Keffer.

* * * * *

Exhibit 186, which shows the estimate of Witness Hammer of the remaining gas reserves of the whole Texas Panhandle Field as of August 1, 1939, is as follows:

Remaining Gas Reserves Texas Panhandle Field.
As of Aug. 1, 1939.

In M.C.F. On a Pressure Base of 14.65 Pounds Per Square Inch Absolute Calculated to 25 Pounds Well Head Gauge Abandonment Pressure.

County and Quadrant	Quadrant Acreage	Remaining Reserve	Remaining Reserve Per Acre
Hartley-HA	32,906	451,255,418	13,713
Potter I	57,588	1,282,995,311	22,279

Total	1,501,719	22,420,439,224 M.C.F.	

The witness did not take into account the open flows of the wells in making his fieldwide estimate, but he did take into account the production from each well in the field. He stated that the wells along the axis of the field generally have good open flows, although he could not give the open flows of any of them. He stated that he did not find open flows essential in making his estimate.

Q. Certainly in evaluating reserves you were interested in knowing what a well would produce, weren't you?

A. In the volume removed, yes, of the metered gas.

Q. The ability to produce, weren't you interested in that?

A. Not in the sense of reserves. Open flow had nothing to do with that.

Q. What makes a large well, anyway?

A. Pressure and a large permeability.

Q. How about porosity?

A. Porosity doesn't have any particular relationship to the question of open flow.

Q. What is porosity?

A. Porosity?

Q. Yes.

A. It is the void existing between the solids in any given rock.

Q. It is the void space in the rock formation which is filled with gas? I say, "void filled with gas." It would be gas if it didn't happen to be something else. It is the porous space in the rock?

A. It is the porous space. As I said, it is the void between the—

Q. And porosity particularly determines the amount of gas you have in place per acre, porosity and thickness?

A. If you could determine it, it would.

Q. Answer my question.

Mr. Reporter, please read the question.

(The question referred to was read by the reporter as set forth above.)

The Witness: Well, naturally, the size of a reservoir always determines—

By Mr. Keffer:

Q. In stating again—

Mr. Lange: Let him finish his answer.

The Witness: Please let me finish.

Mr. Keffer: I beg your pardon.

The Witness: The size of the reservoir capacity always determines the amount of gas present.

By Mr. Keffer:

Q. How do you get reservoir capacity? What are the two things that determine reservoir capacity?

A. Pressure and porosity.

Q. Pressure and porosity and sand thickness?

A. Yes.

Q. Now, those are the three things and the only three things. In fact, pressure—strike that.

In fact, sand thickness and porosity are the only two things that determine reservoir capacity?

A. Sand thickness and pressure.

Q. Pressure will tell the amount of gas you can get into a certain space under a certain pressure but the space, the important thing is spaces which carry the gas, that is, the cubic content of those are determined entirely by porosity and sand thickness?

A. That is right.

Q. Then the volume of gas you have in those porous spaces is determined by the pressure you have in the reservoir?

A. That is right.

Q. Then there isn't any question if you knew sand thickness and porosity and pressure you could figure the field more accurately that way than in any other?

A. If you knew them.

Q. "If you knew them," you would go that far?

A. If you actually knew them, yes.

Q. You do know in many cases and in many fields where the porosity and sand thickness method has been used in estimating reserves?

A. In sandstone reservoirs.

Q. Sir?

A. In sandstone reservoirs.

Q. That is right.

What would be the difference in estimating a sandstone reservoir and a dolomite reservoir?

A. Because you can determine—in most cases you can determine your porosity in a sandstone reservoir because you can get out good cores, but—

Q. If you—

A. Let me finish.

—in limestone reservoirs you can't do it because you don't get out the cores and you can't determine from point to point the variables that enter into it.

Q. As a matter of fact, the early estimates of this field made by everybody were made by the utilization of the porosity sand thickness method, were they not?

A. I don't know how the early ones were—

Q. You have read of estimates, haven't you?

A. Yes, sir.

Q. Weren't they all based on that method? Did you ever see one that used the pressure decline method?

A. I believe that the early ones were.

Q. That is right.

Well, now, do you say that those fellows knew absolutely nothing about the way of determining them?

A. No, I didn't say that. I said they were jumping at conclusions, perhaps, in utilizing ideas of porosity which they couldn't substantiate.

Q. All right, what kind of an estimate would you have made if you had made one ten years ago?

A. Ten years ago?

Q. Yes.

A. Well, ten years ago I would have probably used or attempted to use the same method.

Q. You mean the pressure decline method?

A. No, I mean the—

Q. The porosity and sand thickness figures?

A. Yes. As I explained in my written statement, it is a progressive thing. In the early stages of the field where you don't have the factual data necessary you have to resort then to something else, but when you reached that point

where you do have the factual data, then the other things eliminate the earlier guessing that you were forced to employ.

Q. You then questioned the early estimates?

A. That is right.

Q. Although you would have made the same sort of an estimate?

A. In the earlier stages, certainly, because at that time there was no other way to do it.

Q. Why wasn't there some other way to do it?

A. You didn't have enough factual data over the field to utilize it.

Q. You say that you haven't enough factual data. Explain what you mean by that. Expand on that. Tell us what you mean.

A. There hadn't been enough wells drilled over the field; there hadn't been enough indices established between the volume removed and the pressure decline. In other words, you didn't have an index covering the field ten years ago that would give you the information necessary.

Q. You have a great many areas in which there have been no wells drilled?

A. A few, but in relation to the total area, they are relatively small.

Q. But you did have pressure declines, didn't you, in 1930?

A. Pressure declines in a newly developed field where there are only a few wells, it is a dangerous thing to attempt to use it at that stage of development.

Q. Well, take a situation—I still can't frame your answer. You say you don't have enough factual data where the thing would work properly. Can you state why it wouldn't work with the factual data you had at that time? Is that question clear to you?

A. I am not sure that it is.

Q. Let me see if I can't state it a little differently.

You have a situation where you use a method that you say is bad but it is the best that you can do. Obviously, you think that under the conditions of ten years ago the porosity sand thickness method under conditions then existing than the pressure decline method?

A. I wouldn't even make that comparison.

Q. No?

A. In the earlier stages you couldn't utilize the pressure decline method. You didn't have any choice.

Q. You didn't have enough tools there to do it?

A. That is right.

Q. You had to take the second best, is that what you figured?

A. Well, you can call it that.

Q. In your terminology you would rank pressure decline first and porosity second?

A. As it applies to the Texas Panhandle field I would say that in my opinion as of today where you have the great mass of factual data you have that there is no choice—

Mr. March: Mr. Keffer, May I ask a question here?

Mr. Keffer: Surely.

Mr. March: Could you in 1930 have made anywhere near an accurate estimate of the reserves as you can now?

The Witness: No, not at all.

Mr. March: Could you have made an accurate estimate at all by using the porosity thickness method at that time?

The Witness: You would have the same problem there. You wouldn't have had sufficient wells drilled over the field to have given you any information that would have particular value for the field as a whole.

Mr. March: Your estimate wouldn't have been very much in 1930?

The Witness: Not a great deal.

By Mr. Keffer:

Q. Now, as a matter of fact, Mr. Haumer, can you draw me a line and tell me how much experience you ought to have with respect to the producing formations before you can begin applying the pressure decline method with some degree of certainty?

A. Well, I think this field has reached that stage.

Q. About when did it reach it, in your opinion?

A. Well, it is a progressive proposition—

Q. I appreciate that.

A. —and more factual data were collected from year to year and from time to time whereby you could more nearly approach a condition where you ought to get the best answer.

Q. In other words, as time goes on the better your answer, isn't that it?

A. That is true.

Q. When a field is fully depleted, any one can tell how much was in it to start with?

A. If it had been properly metered out.

Q. I think I could do that. I think anybody that could add could do that.

A. That is true.

Q. I think that is obvious. The nearer you approach that the more accurate your estimate is?

A. That is correct, the more data you have.

Q. If you made an estimate next year it would probably be a little different than the estimate you are making this year?

A. It would probably have some variations.

Q. If you made an estimate last year it would be slightly different from the one you would make this year?

A. The estimate of reserves by any method is never a complete thing because of certain factors that are inherited in the problem.

Q. You haven't quite answered my question, but let me state it again.

Using the pressure decline method, every time you make an estimate from year to year you get a different figure, is that correct?

A. Well, slightly different, maybe, but not any great difference.

Q. Suppose it did differ greatly, what would you say then about it?

A. Well, if you have the right sort of factual data, and you have done the right sort of a job in the first place you shouldn't have any great variation.

Q. I know that, but still you don't answer my question.

I said, suppose you did have a great variation, what would that indicate?

A. I think I answered your question. If you have done your work properly in the first place, the corrections that you would get by the following year or two wouldn't or shouldn't greatly change the shape of any curve that you might use.

Q. Getting back to my question, suppose you had done all of that properly and suppose it does change that curve—that is my question—then what do you say about it?

A. Read that question, please.

(The question referred to was read by the reporter, as set forth above.)

The Witness: Well, if the actual facts change an answer, it is a changed answer and that is all there is to it.

By Mr. Keffer:

Q. It shows your former estimate was wrong, doesn't it?

A. Whatever slight variation there is.

Q. I am not assuming any slight variation, Mr. Hammer, I am assuming a substantial variation.

A. Well, it would prove that your previous estimate—we are assuming all the time your factual data is one hundred per cent true as near as you can get it—

Q. Go ahead and make that assumption.

A. In that case I would say that you would not have any great variation—

Q. All right, but getting back to my question, I am assuming all of that and still there was a substantial variation, then what would your answer be to that?

A. Well, I just stated that whatever the answer was would be the answer and if it were slightly higher or lower it would show that variation.

Q. You keep using the word "slightly." I am assuming it is substantially lower or higher as the case may be.

A. Well, as I see the question, and as I stated a while ago, if the work is properly done you are assuming something that isn't apt to happen at all.

Q. I know, but indulge me the privilege of making an assumption—

Mr. March: I will help you—

Mr. Keffer: I think I can do it all right.

Q. Let me make the assumption which I have made and then tell me what would be your judgment of a situation like that. What would it indicate?

A. Well, it would indicate a variation in the estimate.

Q. Certainly.

A. You might make another estimate, we will say, the next year or so and it might vary in the opposite direction—

Q. But you are still not answering my question.

A. I have. As I see it I have already answered your question.

Q. Not as I see it.

If you have made estimates on rock pressure decline method this year and you have found next year that by utilizing the same method you get a substantial variation from what you got this year, what would that indicate to your mind with respect to the availability of the pressure decline method for estimating reserves in this field?

A. I see, I think, where we are not on the track. We have not utilized any one year; we have utilized the factors over a period of five years, and I don't believe anyone is justified in taking the data from year to year and attempting to arrive at an estimate.

Q. All right, then, I will broaden my question.

Take the five-year period which you have utilized and made your estimate on and your estimate in 1939, then you find out that in 1940 you got entirely a different answer using the same method, then what would you say?

A. Well, I would say that with the added year of factual data, if there was a variable, that probably indicated the later estimate was the best.

Q. Probably? Don't you know it would be the best?

A. I said "probably."

Q. All right, then, getting back to the original question—back to the question I asked a while ago—the longer your period the better your estimate? There can't be any argument about that, can there?

A. That is true. The longer period of actual factual data, the better off you are.

* * * * *

He stated that the greater the porosity of producing formations the greater the production, but it would not necessarily follow that the greater the open flow the greater the production. He was then asked if you could produce as much gas from a five million cu. ft. open flow well as you could from a twenty million cu. ft. open flow well, and he answered that certainly you can produce more from a larger well than from a smaller one.

The permeability has less influence on gas production than on oil production. Gas will pass through a porous space with more ease than will oil. A big oil well requires a large factor of permeability but you can have a big gas well with lower permeability as compared to oil. Permeability retards the flow of gas much less than it retards the flow of oil. He didn't know whether permeability or porosity has more influence in the Texas Panhandle Field in determining the size of a well, but permeability retards the flow of gas or the migration of gas from one point to another in a structure to a much lesser degree than is true of oil. You may have a formation the permeability of which is such that there would be little migration of oil into the well bore, yet the same type of formation with the same permeability might permit a large volume of gas to flow into the well if gas were encountered instead of oil.

Porosity, simply stated, is the void spaces existing between solids in any given reservoir. Permeability is the measure of flow of the gas through that formation. You might have a twenty percent porosity in Well A, and twenty percent porosity in Well B, but the gas would not necessarily flow as rapidly to the well bore in one as it would in the other because of the possible variation of the characteristics of the reservoir rocks themselves, such as the angularity of the material that makes up your formation. This would have some effect. For instance, you might have one reservoir filled with round rock that would have certain porous spaces. Gas under those conditions would pass through readily. You might have the same reservoir with the same porosity but the solids would be angular and of all different kinds and shapes, and yet in that case the gas would pass through it with lesser ease. In other words, it wouldn't pass through so rapidly. You have a higher

permeability in perfectly round grains of sand than in those that are irregularly shaped.

The gas producing formations in the Texas Panhandle Field are not composed of sand, but of dolomite. Dolomite is a rock consisting principally of magnesium and calcium carbonates, and is fairly hard. You have running through all of that dolomite formation porous spaces that are rather like pipe lines leading through there in all directions, but generally on a horizontal level, but you also have running throughout that dolomite variables in porosity. There is running through the rock producing formation hundreds and maybe thousands of porous spaces running horizontally, vertically, or at almost any level. The porous spaces may be honey-combed like a piece of honey-comb. Gas could migrate long distances in a honey-combed formation if the porous spaces were interconnected.

The pressure conditions in the Texas Panhandle Field indicate that the porous spaces throughout the field are inter-connected. This is shown by the isobar lines on the Isobar Contour Map (Exhibit 179) prepared by witness.

The witness had never examined any cores from the formation where the greatest flow of gas was discovered because they were never able to get a core out of that area, but the entire thickness of the producing formation contains more or less porous spaces and the witness had seen cores where porosity tests had been run in the harder part of the formation, and according to statements made to him, those cores contained considerable prorous spaces, but he did not recall the extent of the porosity. He probably looked at half a dozen cores in all. He made a notation concerning them but didn't have it with him. He took a photograph of the cores in question then discussed the entire matter with employees of Phillips Petroleum Company who had taken the cores out of the racks for him. He discussed the matter with the research department and with their field superintendent and geologist but he made no physical examination of the cores. The cores showed that there was more or less porosity all through the dolomite.

Permeability is a less important factor from the standpoint of gas production than from the standpoint of oil

production for the reason that gas will flow through a porous media much more rapidly than a fluid of any type, but he does not believe that permeability varies directly with porosity in the Texas Panhandle Field.

Gas under high pressure flows rather rapidly through angular obstructions, depending upon your permeability factors, and would move with more ease than would either oil or water. It would be necessary to know what the permeability was before you could tell whether the movement of gas would be slowed down under high pressures.

The witness further testified (Vol. 55, pp. 7689-7700) as follows:

Q. You know gas under high pressure flows rather rapidly in these angular obstructions you talked about, and wouldn't that have a tendency to slow down the gas flow very much?

A. It would all depend upon what your permeability factors were?

Q. I am assuming your angular situation which you referred to a while ago, your gas under high pressure would nevertheless migrate rather readily where oil or water wouldn't hardly move at all—

A. It would move through with more ease.

Q. You would have to have a most unusual situation in your porous space to slow down the movement of your gas very much under these high pressures, wouldn't you?

A. Well, you would have to know—in order to answer that you would have to know what your permeability was.

Q. I realize that, but the fact still remains that this gas will move rather readily through this porous media regardless of whether it is smooth all the way through there or whether you have these angular matters sticking out into your pores?

A. No, you can't make that comparison at all. You can't set up a condition underground and produce imaginary tubes running horizontal in a formation which gas would flow through. That sort of assumption is absurd.

Q. Will you tell me why it is so absurd?

A. I have just told you.

* * * * *

Q. Mr. Hammer, did you state this morning the number of cores Phillips Petroleum Company had taken of various wells in the field?

A. No, I didn't. I don't know how many.

Q. Do you have any idea of about how many it was?

A. No, I don't have any idea of how many it was.

Q. Would 1500 sound about right?

A. How many?

Q. 1500.

A. 1500?

Q. Yes

A. I have no idea of how many there were.

Q. How many did you see when you were looking at them in the room?

A. Well, that would only be an estimate. There were a lot of racks full of them, filling quite a good-sized shed. I wouldn't know how many there were.

Q. You are not as good in estimating the number of cores as that efficiency expert I heard of one time who was good in estimating a large herd of sheep?

A. No, I don't estimate that way.

Q. I believe you stated you made no determination of those that you saw either as to porosity or peremeability?

A. That is right.

Q. Did you get any information from the employes as to what percent was of porosity or permeability?

A. Just general statements. I made no notes on them when we discussed them.

Q. In other words, you more or less ignored those cores as having any useful service in making this estimate, is that correct?

A. Yes, I think that can be stated as being true.

Q. Do you have any idea why the Phillips Petroleum Company had those cores made?

A. They were looking for information on the producing horizon.

Q. That is right. It was rather expensive to take those cores, wasn't it?

A. Yes,—

Q. Phillips Petroleum Company evidently thought they were worth something, didn't they?

A. Yes.

Q. Or they wouldn't have taken them?

A. Yes.

Q. Very well. What information could the Phillips Petroleum Company get from them?

A. I think they were disappointed in that they—as I stated, they never got any cores that gave them any information through that part of the strata that gave the major flows of oil or gas.

Q. Assuming they were disappointed, they were certainly very persistent in keeping on taking them, if they did take a number, weren't they?

A. It is my understanding they didn't continue that for a very large number of years for the reasons—

Q. You say those cores—

Mr. Lange: Let him finish the answer to your question.

The Witness: For the reason they found out that the pressure of the column of mud in the rotary drilling acted upon the producing horizon and had a tendency to force the mud into the formation and they had difficulty in cleaning the wells out so they did like everyone else does, they quit utilizing, as I understood it, a rotary for the completion of their wells.

* * * * * *

Q. Now, you do know, Mr. Hammer, that tests of oil reserves, or estimates, rather, of oil reserves, are ordinarily made by the porosity sand thickness method, don't you?

A. It is a usual thing, I believe it is.

Q. I didn't get that.

A. I said, as a usual thing I believe they are.

Q. That is correct.

A. There are so many exceptions.

Q. That is right, there are many exceptions, but when you have a water drive, for example, where your pressures remain constant, I don't know whether there are exceptions there or not, because after all, you would have to have your porosity and sand thickness there as in other cases, wouldn't you?

A. That is right.

Q. What are the exceptions where the oil reserves are not estimated by porosity sand thickness method?

A. Well, in recent years; since proration, for example, has come into the state of Texas so strongly and where development has gone on—

Q. Where development has what?

A. Where development has gone on continuously in the field I think they varied that somewhat, but in a general even that is true as far as oil is concerned.

Q. We agreed this morning that permeability has less bearing upon gas producing formations and the flow of gas through a porous media than it does as to oil, didn't we?

A. In general we did, yes, sir.

Q. That is right. Then if you can estimate oil by the porosity sand thickness method, there is still greater accuracy in estimating gas reserves by that method, is that not true?

A. No, I wouldn't say there is any great accuracy.

Q. Your permeability factor doesn't throw you out of line so much, does it?

A. The permeability when you are estimating by porosity doesn't have anything to do with it.

Q. Is it not very common to estimate oil reserves based upon the size of the wells drilled, the producing ability of the wells?

A. I don't believe that would hold true.

Q. Are you stating that for a fact it is not true?

A. What do your mean—let me see if I get your question. You mean that you could tell the amount of oil reserve under any given amount of acreage by the flow of oil from that well?

Q. Not necessarily that. In determining the relative acre content, it is quite customary for oil companies to rely upon the producing ability of the wells for the determination of that fact?

A. Well, no. In limestone reservoirs I couldn't say that is true.

Q. I am talking about a dolomite reservoir.

A. That is what I am talking about.

Q. On what kind of reservoir is it true?

A. Well, it might be more nearly true as far as certain types of sandstone reservoirs are concerned.

Q. What would be the difference between sandstone and dolomite?

A. Sandstone is one that usually has a more uniform porosity than does a limestone or dolomite.

Q. Well,—

A. Let me finish my illustration.

Q. All right.

A. If you wanted them, I could give you five hundred of them, more or less. I have seen limestone wells where a well would come in and produce at the rate of three thousand barrels a day flowing; I have seen as many as six wells drilled on 160-acre tracts, the largest of which was never more than three hundred barrels. Now, that is a common thing to expect in a limestone reservoir as far as oil production is concerned.

Q. Do you find that is true in the brown dolomite in the Panhandle?

A. As I say, I have made no particular study of oil production.

Q. From your general knowledge you should be able to answer that question. There is a great uniformity of areas with respect to the production of oil and the size of oil wells in the brown dolomite in the Panhandle field?

A. I haven't checked them.

Q. You have found that is true in the gas section of the brown dolomite?

A. I don't know as having paid any attention to it.

Q. What makes a big gas well?

A. What makes a big gas well?

Q. Yes.

A. Well, you are talking about a big gas well in a limestone reservoir?

Q. In the Panhandle field in the brown dolomite.

A. Well, a big gas well necessarily means a large volume of gas coming out, and that is dependent largely upon the factor of the permeability surrounding a well.

Q. And what else?

A. Well, it necessarily follows that you must have a good reservoir condition.

Q. Isn't that some indication of porosity?

A. It is so, yes.

Q. That is right. If you get a big gas well you are almost certain you will have a higher porosity?

A. Not necessarily.

Q. Isn't that generally true in this Panhandle field?

A. I wouldn't say it was.

Q. Would you say it wasn't?

A. You are neglecting your permeability factor entirely.

Q. I know it, but would you say it was not?

A. Would I say it was not an indication of porosity?

Q. That is right.

A. Well, I wouldn't want to go that far, no.

Q. All right, then, you just haven't studied it from that angle, is that correct?

A. That is right. The method we used doesn't depend upon the questions of permeability or porosity.

Q. You made no particular search or investigation to determine whether that is true or isn't true?

A. As to whether what was true?

Q. Whether a big well indicates high permeability and high porosity.

A. Well, I made no particular investigation of that because it wasn't necessary from our standpoint.

Q. Then the statement I just made, as I take it, is a correct statement, then, since you attached no particular significance on the approach you made to the problem; you made no particular effort to determine what relationship, if any, did exist?

A. That is right.

* * * * *

The witness does not know the areas of maximum of open flow in the Texas Panhandle Field, it being unimportant to him to study this phase of the matter. He did know that the area of northern Moore County, for example, was an area of large per acre pound decline, but he didn't know as to open flow, whether the wells produced five million cubic feet or fifty million cubic feet. It wasn't important to him. He made no study to determine the size of the wells along the edges of the field and did not know whether they were small or large. This was not important to him.

* * * * *

The witness further testified (Vol. 55, pp. 7710-7726) as follows:

Q. Now take Quadrant 1, Potter County, the wells that you generally *fine* in that quadrant are in the north half of the quadrant, the majority of them?

A. No, I would say that the majority are about in the center.

Q. About the center?

A. Yes.

Q. You have an area in the northwest portion of the quadrant with a few wells in it. There is only one connected well there, is that right?

A. I believe that is right.

Q. So you have there a great deal of undeveloped acreage in that quadrant and you assumed that in the undeveloped acreage—I say "undeveloped," but I mean fairly good-sized areas in which wells have not yet been drilled—the wells, when and if drilled in that area, will be about the same size of the wells that have been drilled in that area?

A. Well, in my study of this situation in general I didn't go over the field making assumptions about what new wells would be. It wasn't necessary.

Q. You did assume that your acre content would be about the same as reflected by the wells already drilled?

A. I am glad you asked that question.

Q. All right, I am glad I asked you one you wanted to hear.

A. Don't interrupt me until I get through.

Q. All right, make the answer relevant to the question I asked you.

A. Surely. You take a given amount of production taken from a group of wells in an area and the larger the area where you utilize simply that production, the lesser amount of gas per acre pound than if you used a small area.

In other words, the utilization of undrilled acreage gives you a minimum reserve because you are taking a maximum amount of acreage into consideration, so the question of size of the wells hasn't anything to do with the question of reserve. You take a large area and a smaller amount of production and apply it to that area and you will get a minimum result because of the distribution over the larger area.

Q. Well, I don't think I quite understand that last statement of yours, "you get a minimum result." I wish you would explain that to me. I just don't catch it.

A. Well, suppose, for example, that you had a group of, say, ten wells on five hundred acres and it was possible—I wouldn't advise it, but take it as an illustration—you drilled, we will say, five wells on a thousand acres. You calculated and drew your isobars and calculated for that thousand acres the production per acre pound for that area.

All right. Then if you took, say, instead of one thousand acres, two thousand acres, and drilled more wells but applied it to the production from that one thousand acres to your two thousand acres you would have a lesser production per acre pound.

Q. Why wouldn't you have twice as much?

A. You would have less because you have more acreage. Your acre factor enters into that.

Q. What I am talking about is reserves. If you take two isolated tracts, one of them containing one thousand acres that has five wells upon it; then take another one that has two thousand acres having five wells that are identical in every respect in the things which you have considered in arriving at reserves, wouldn't you come out with just twice the reserve in the 2,000-acre tract more than you would come out with in the 1,000-acre tract?

A. Let's see. Your question was, if I get it, if you had identically the number of wells and the identical number of production on a thousand acres?

Q. That is right, and identical performance.

A. And the identical amount of gas had been taken out?

Q. Yes.

A. And you utilized—and you made a calculation on the smaller area?

Q. That's right.

A. Then you had an identical number of wells and an identical number of—no, and a larger amount of acreage, would your reserve estimate be larger in one case than in the other, is that right?

Q. Be twice as much on the 2,000-acre tract as on the 1,000-acre tract.

A. You are neglecting, Mr. Keffer, your acreage factor in your computation. It would be less than a smaller per acre—I am talking about undeveloped area.

Q. You mean you would have less content per acre in the two thousand?

A. You would have an indicated less production per acre pound.

Q. That is not what I am talking about. I am talking about acre content of gas in place.

A. Well, but you arrive at your gas in place by the utilization of your acre pound factor.

Q. Well, all right. Let's assume another situation. You have an area of a thousand acres in which there are five wells drilled; then you expand that area outside the lines, expand it so you will have two thousand acres with just the same five wells drilled, same performance and everything else. Would you say you wouldn't have twice as much gas under the two thousand as you would have under the one thousand?

A. Certainly not, simply for the reason that there is distribution of that gas under a large area.

Q. I know you are distributing it.

A. You would have a lesser production per acre pound.

Q. You wouldn't have as much if that was a perfect reservoir, I can understand you wouldn't have as great a per pound drop for the volume produced, but I am talking about gas in place.

A. That's what I'm talking about.

Q. How do you determine gas in place? I've got it all backwards, then. . .

A. Well, I'll try to explain it so that you will understand.

Q. That's right.

A. You understand, I think I have explained often enough how we arrived at our weighted pressure.

Q. Yes, I think I understand that.

A. All right. Then we take that weighted pressure and we calculate from that the production per acre pound decline as against the weighted pressure.

Q. Yes.

A. See?

Q. Yes.

A. All right, that production per acre pound decline, then you take that. You have in there production per acre pound decline. You have in there three factors, don't you? You have production; you have acreage; and you have pressure—pressure decline. All right, you simply take your acreage and you multiply that by your pressure drop;

then you multiply that by your 35.1 Mcf., see? In other words, you then have your acreage and you have your pressure and you have your Mcf. Now the *compulation* of those three will give you the product per acre pound All right, then you have so many acres and you calculate the reserve for the number of acres.

Q. The production per acre pound. Then you make one more computation and you get the gas in place per acre, don't you?

A. It amounts to the gas in place per acre pound decline.

Q. Well, let's get off of that per acre pound. Now, the exhibit you introduced here this morning shows, well, I don't seem to have it here, but it shows the remaining reserves down to 25 pounds per acre, not per acre pound decline or anything else, but the number of—volume of gas per acre.

A. Yes, that is right.

The Trial Examiner: Mr. Keffer, may I interrupt you a moment?

Mr. Keffer: Yes.

The Trial Examiner: Mr. Hammer, do you make a determination of your acreage area prior to your calculation, or—

The Witness: Oh, yes, prior to your calculation. You know the total amount of acreage involved in each quadrant, see?

The Trial Examiner: Yes, and you made that prior to the time that you calculated the reserves in place?

The Witness: Prior to it?

The Trial Examiner: Yes.

The Witness: Yes, certainly.

The Trial Examiner: What I mean is, not to get down to this figure here, but I mean prior to the time that this calculation which you described was made.

The Witness: Well, the determination of the acreage in a quadrant and the determination of the weighted pressure is the first step that you take.

The Trial Examiner: Yes, that's what I wondered.

The Witness: That's right.

By Mr. Keffer:

Q. All right, now you have calculated it in Quadrant A, we'll call it, and you got an original reserve. Let's get it back to originals and we can compare it better. You got an original reserve of 10,000,000 feet per acre. You take that same setup and apply it to another quadrant that contained a thousand acres and it would naturally figure out ten million feet per acre on that one, too, wouldn't it?

A. Well, that's one way, but you are still neglecting—

Q. You can answer that yes or no.

A. Yes, you're right—

Q. Now, wait, I want to ask you another—

Mr. March: He can make an explanation if he wants to. He can say yes and then he can make an explanation.

Mr. Keffer: All right, go ahead.

The Witness: You are leaving out of there—what you have arrived at when you come down to that is a figure that has already taken into consideration the production per acre pound decline, scattered over the entire area.

By Mr. Keffer:

Q. All right, now let's talk about original reserve per acre, which is a very simple calculation to find when you have your acreage per pound decline on your method, isn't it?

A. All right.

Q. All right, now, we have got original reserve per acre of ten million feet per acre, original reserve, in Quadrant 1; then you have another identical quadrant with identical wells, with identical performance, that also contains a thousand acres, and that, since everything is identical, you would come out with that at ten million feet per acre, wouldn't you, original?

A. Now, what you mean—there is one thing that is confusing.

Q. Precisely what I said. I can't state it any clearer.

A. Repeat your question, please.

(The question referred to was read by the reporter, as set forth above.)

The Witness: You are talking about original. What do you mean by reserve?

By Mr. Keffer:

Q. Gas in place, there before any is produced.

A. I haven't given you any figures on that.

Q. I know you haven't but you could get that readily from the figure that you did give me. I could figure that out if I had what you just gave me.

The Trial Examiner: Well, now, let me see if I get your question, Mr. Keffer. You are talking about a quadrant that he has established a reserve on and then assuming—

Mr. Keffer: Another identical quadrant.

The Trial Examiner: Yes.

Mr. Keffer: With the same identical wells and performances and pressures.

The Trial Examiner: In another area?

Mr. Keffer: Sir?

The Trial Examiner: In the same area or another area?

Mr. Keffer: It wouldn't make any difference. They can be joining as far as that is concerned.

Q. Am I right in what I stated, Mr. Hammer?

A. Read what he stated.

(The record referred to was read by the reporter, as set forth above.)

By Mr. Keffer:

Q. All right, now, wouldn't you?

A. You would come out with—let's see if I get this straight. If you had one area, a small area—

Q. Yes.

A. —where you get, we'll say, ten million per acre and then identical stuff in a larger area?

Q. No, the same size area, another thousand-acre tract.

A. Another thousand-acre tract?

Q. Identical in every respect, you would get the same figure per acre content, wouldn't you?

A. If identical in every respect?

Q. Yes.

A. Exactly identical, yes.

Q. Yes, no deviation at all.

A. All right.

Q. You then get ten million per acre on that other one, wouldn't you, Quadrant B?

A. If everything were identical?

Q. That's right.

A. Oh, yes.

Q. Well, we are together that far, aren't we?

A. I guess so.

Q. There is no mistake there. Then you have twice as much in that, then throw the two quadrants together you would have twice as much in the two-thousand-acre quadrant as you would in either one of the thousand-acre quadrants, wouldn't you?

The Trial Examiner: You mean just add the two totals?

Mr. Keffer: That's all there is to it. It is very simple.

The Witness: Well, under that sort of an assumption you would have twice, all right.

By Mr. Keffer:

Q. Well, that's what I thought. I guess maybe I thought you said a while ago you would have less than twice as much under the two thousand than under the one thousand.

A. Yes, but the analogy wasn't the same.

Q. I intended to make it precisely the same. Where is the difference in the analogy? Maybe we'll learn something here.

A. Well, it's hard for me to explain it any further than I have, but the point is that if you have two areas—take your same illustration—you have two areas of different sizes in the one area, a small area, we'll say. You *arive* at a production per acre pound from the production that came from those wells in that area, see?

All right. Now, if you have an area, we'll say twice that large, as you have illustrated, and you take the same production, assume that you had the same production from the same number of wells and you spread that over the larger area, you are bound to get a less production per acre pound.

Q. Why, of course. I can understand that. It is very simple, but when you reduce that or convert that over to

original reserves per acre content, you are going to have just twice as much gas in the ground over the larger area.

A. No, you aren't.

Q. Then you would have in the smaller area.

A. No.

Q. We're right back where we started. I guess we've spent enough time on that, anyway.

The Trial Examiner: I think the record is clear on that, Mr. Keffer—I mean, I think you are talking about one thing and Mr. Hammer is talking about another.

Mr. Keffer: I think that's right, and Mr. Hammer persists in talking about per acre pound decline, while I talk about per acre content. I think that's the whole difference. I don't know whether it is or not, but we'll leave that.

The Trial Examiner: In other words, Mr. Hammer has fixed these reserves for his quadrant. Now, you were assuming two quadrants, you see, Mr. Keffer, and I think that is where the misunderstanding occurs. In other words, as I got your question you were throwing this ten thousand acres into Mr. Hammer's one-quarter in one instance, and in this other instance you are talking about two hypothetical separate quarters.

Mr. Keffer: I was trying to segregate, Mr. Examiner—reduce it to a point of acre content, if you had twice as many acres and had the same acre content you would have just twice as much gas. Now, I think that ought to work out that way in Mr. Hammer's way of figuring it or anybody else's way of figuring it, but if it doesn't work out that way in Mr. Hammer's way of figuring it, I want to know why, and if it doesn't, then I think something is wrong with Mr. Hammer's method.

The Witness: You have been talking about an acre, haven't you?

By Mr. Keffer:

Q. Yes.

A. This thing that I have just been mentioning so often is production per acre pound.

Q. I know, but that isn't what I have been talking about.

A. But that is the production per acre pound that has come out of an acre of ground.

Q. What good have you done when you get to production per acre pound if you stop there?

A. You don't stop there.

Q. Of course you don't. You go on another step and do what?

A. Well, you take your area and your weighted pressure and you calculate your reserve.

Q. You find the number of cubic feet per acre multiplied by the number of acres and that gives you the reserve of your quadrant, don't you? Isn't that right?

A. Let's see, you multiply your acreage—

Q. Your acreage content by the number of acres in your quadrant and that gives you the reserve in your quadrant.

A. No, not in the utilization of a production per acre pound.

Q. Well, just another minute or two and then I'm going to leave this. You have your per acre pound drop in pressure.

A. That's right.

Q. All right, then, tell me where you go from there and how you get there.

A. Well, I just explained it a few minutes ago.

Q. Let's do it again.

A. You take your area involved, see?

Q. The number of acres in it?

A. The number of acres, and you multiply that by the pressure drop between any two given pressures, that gives you your production—no, that gives you your per acre pound factor; then you have calculated a production per acre pound and you multiply that by the Mcf. and you get your reserve.

Q. Per acre?

A. No, for the area.

Q. For the area. All right, then, if you divide by the number of acres, then what happens?

A. You don't divide.

Q. I know, but we'll just do it this time. What would you get?

A. It would be a wrong assumption and it isn't anything that has, as I see it, a bearing on the question of reserves. You would be doing things wrong.

Q. I don't think it does much, either, Mr. Hammer, but I don't know. I'm just trying to see if it does.

Now, this Exhibit 186 introduced this morning, you show remaining gas reserves per acre in Hartley-HA, 13,713,000. Now, how did you get that figure?

A. Well, on this particular sheet I divided the remaining reserves as calculated here by the acreage.

Q. That's exactly what I said, and you just said it wouldn't give you anything, didn't you?

A. There was a misunderstanding there as to what you were trying to get at.

The witness then testified (Vol. 55, pp. 7726-7782) as follows:

Now, what causes drainage in a gas field, Mr. Hammer?

A. Pressure differential.

Q. Do you have pressure differentials in the Panhandle field?

A. Oh, yes, there are pressure differentials in the Panhandle field.

Q. Where are the lower pressure areas generally?

A. In that field in general they are along the northeast side of the field.

Q. What has made those low pressure areas on the northeast flank of the field?

A. Gas withdrawals.

Q. Where?

A. Well, along the northeast side of the field.

Q. That's right, as gas has been withdrawn along the northeast flank and low pressures were formed in there, what happened?

A. As gas was withdrawn and low pressures formed, what happened, you say?

Q. That's right.

A. Well, a lot of things happen. There was a general tendency—a general tendency for gas to move from the higher to lower pressure areas.

Q. You say "general." Isn't that an unavoidable tendency or an unavoidable result?

A. Well, there are all sorts of degrees as to the movement of gas.

Q. I appreciate that, but it moves, nevertheless.

A. It has a tendency to move all right.

Q. Well, doesn't it move? Let's cut out the word "tendency" and say that it does move.

A. It isn't that—

Q. Isn't that right?

A. Well, I would rather leave that, that the movement is a variable condition but that there is—

Q. But there is, nevertheless, a movement?

A. There is a movement.

Q. That's right.

A. It will vary in degrees very considerably.

Q. That's right, the movement is from what point to what point?

A. Naturally it is from the high to the low pressure areas.

Q. Just on the same principle that water runs downhill, isn't it?

A. Well, I suppose that would be a good explanation.

Q. It is impossible without some exterior force for gas to move from a low pressure area to a high pressure area, isn't it?

A. I have never heard of it being done in a gas field.

Q. I don't think you ever will. In fact, that is Mr. Boyle's law to a degree, at least, isn't it?

A. That's right.

Q. All right, now, the areas along the northeast flank of that structure are generally low, practically from one end of the field to the other, is that not correct?

A. No, not the entire distance.

Q. Well, let's start from a point, say in the northwest portion of Hutchinson County.

A. If you would start from an area in the vicinity of the Borger field and go from there east, I would agree with you in general.

Q. Well, why couldn't you start way north of Borger? Here is Borger, and way up here just opposite the word "Hutchinson," wouldn't you be getting low pressures there on the northeast flank of the field? I am referring to Exhibit 179.

A. They are all degrees of pressure, Mr. Keffer. That

area up there in northwest Hutchinson County in 1939 was a relatively high pressure area.

Q. That's right, but is it today?

A. So you can't say that that is a low pressure area.

Q. All right, let's take, then, from in the vicinity of Borger and going on down through the length of the field. Which direction do you go from that line to get into a higher pressure area?

A. You mean from the line that was drawn in making the limits of the field?

Q. That's right, from any point along that northeast flank. Start anywhere you want to.

A. Well, in general, it would be to the—well, toward the east—it would be to the south and west.

Q. All right, as to the movement your isobar lines show that completely, do they not?

A. Yes.

Q. And the farther southwest you go, what do you find?

A. You find higher pressure areas.

Q. That's right. You start southwest from Borger and you will find a higher pressure area, and going a little farther, still higher, and going farther, you will find it still higher, and where do you find the very highest pressure areas in that field?

A. Well, there are three of them, really, at northwest Hutchinson County, the extreme western Moore and part of Hartley County, and the area along the south border of the field.

Q. That's right, you generally find the higher pressure areas at points farther east, away from the low pressure areas along the northwest flank, don't you?

A. In general that is true except that northwest Hutchinson, I would say.

Q. Now, state again just what causes that.

A. Well, I said it was pressure differential between different areas.

Q. And the gas is migrating in what direction on that —from the high to the low, I think you stated that, is that not correct?

A. I have.

Mr. Keffer: I have another map here that is colored which I would like to put up here for just a moment. I would like for this map to be marked as an exhibit for identification. We do not desire to introduce it just now, but it will be introduced later.

The Trial Examiner: It will be marked for identification as Exhibit No. 187.

(Exhibit 187, Witness Hammer, marked for identification.)

The Trial Examiner: Did you state what the map is, Mr. Keffer?

Mr. Keffer: No.

The Trial Examiner: Would you do that?

Mr. Keffer: This map shows the outline of the Texas Panhandle gas field as determined by the Railroad Commission of Texas, showing pressure bands at 20-pound intervals in different colors in order that it might better reflect the bands of pressure differentials in the field.

This color along the northeast side of the structure here, I guess you would call it a slate color or perhaps represents pressures from zero up to two hundred pounds; that is, nothing up above two hundred in that area and nothing below zero.

The next band, which is I guess an orange color—anyway, it is this color here that I am pointing to—is two hundred to two hundred and twenty pounds pressure.

The next is a dark blue band which is two hundred and twenty to two hundred and forty pounds pressure.

The next is a pink bank which is two hundred and forty to two hundred and sixty pounds pressure.

The next is a green band from two hundred and sixty to two hundred and eighty pounds pressure, and the next is a red band from two hundred and eighty to three hundred pounds pressure.

The next is sort of a purple band from three hundred to three hundred and twenty pounds pressure.

The next, I guess is colored a light green.

Mr. March: That's right.

Mr. Keffer: A light green, from three hundred and twenty to three hundred and forty, and then a light blue, lighter than the previous blue that we referred to, is three hundred and forty to three hundred and sixty, and then, what is that, Mr. March—Mr. March says it is a brownish green. I guess that's just as good as any, is three hundred and sixty to three hundred and eighty, and then a pink from three hundred and eighty to four hundred, and then a yellow above four hundred pounds pressure.

Q. Now, will you examine that map generally, Mr. Hammer, and tell me if it is a rather accurate presentation of the pressure differentials existing in the field as of July 1, 1939?

Mr. March: Now, if it please the Examiner, we don't object to this witness answering any question in regard to the entire Panhandle field. We don't even object to the witness being cross examined about the porosity thickness method which he did not use, but we do object to this witness being cross examined about an exhibit that he did not prepare, and an exhibit which has not even been marked for identification or been offered through a witness in this hearing room—

Mr. Keffer: It has been marked for identification and I am not cross examining him on the exhibit.

Mr. March: And in so far as any testimony on this exhibit, which is not Mr. Hammer's exhibit, we think it is unfair to cross examine in regard to it and we absolutely object to such cross examination.

The Trial Examiner: I think, Mr. March, that we have a precedent. Mr. Keffer says that he is not going to cross examine Mr. Hammer on that particular exhibit, but I think we have a precedent for just such procedure established by Commission's counsel. I can recall of Commission's counsel putting on Map 95, I believe it is, and using that very map to cross examine Mr. Watson.

Mr. March: Well, that was with the consent—I mean,

he was testifying in regard to those particular—in regard to Exhibit 95 that is—is that this large exhibit here?

The Trial Examiner: That is right.

Mr. March: That was their own map.

Mr. Keffer: That is not our map at all.

Mr. March: That is their own map, their outline furnished by them to the Federal Power Commission, and as far as Mr. Watson being cross examined about that map, he was not. He was asked to designate on that map, which is merely a map of the Canadian River leases, upon which leases they were going to drill wells.

This is entirely different. There was no cross examination in regard to this exhibit here. We put a witness on and he was cross examined. He merely designated it.

Now, I don't object to Mr. Hammer coming up here and putting crosses on this map that certain leases are designated here and certain blocks and surveys and all of that, but when you take this map that was not put in through our witness and attempt to cross examine our witness in regard to it, that is something unheard of. It is something that we object to most strenuously.

The Trial Examiner: I hadn't heard of it either, Mr. March, but you have done it. It was done in regard to the examination of Mr. Watson. I don't recall whether there was another witness on it or not, but it was done on Exhibit 95, Mr. March. It is just as fair now as it was then.

Mr. March: All he did was mark on there which leases they were going to drill on, and you stopped him on that. You said it would be better for us to have our men do that because there might be some difficulty about that. We stopped that practice and didn't require him to complete marking things. We aren't relying on any markings that Mr. Watson put on Exhibit 95. Our own men took the thing—you ruled that our own men should do it and they did do it, and that is what happened, and there is not a mark on this exhibit, the map, No. 95, by Mr. Watson, that we are relying on.

The Trial Examiner: Perhaps, Mr. March, my memory is short and we will let the record speak for itself, but I don't understand that Mr. Keffer is going to attempt to verify this map through Mr. Hammer.

Mr. Keffer: Not a bit. It is just a picture there that I want to ask him about with respect to the flow of gas as indicated on that particular map. Whether that map is right, I don't ask him to commit himself on it anywhere.

Mr. March: He is going to assume it is right in the first place and then say if it is true, won't this happen. There is the whole thing in a nut shell.

The Trial Examiner: Let's just wait until we get to that point, Mr. March.

Mr. March: All right, we'll see.

By Mr. Keffer:

Q. Now, Mr. Hammer, the map, Exhibit 187, discloses a low pressure area from a point considerably north of Borger that is an area of three hundred pounds or less which is the green pressure band around here (indicating), extending from that point entirely across the field to the southeastward, does it not?

A. According to your interpretation, yes.

Q. Yes, that is what the map shows, is it not? I am not asking you to verify the map; I am just asking you to say what the map shows.

A. Well, if the green, as you said it does, goes across the map as indicated.

Q. All right, and that shows—now, the area marked here in yellow and the area marked in pink, which I am pointing to here, is in the Canadian River block, is it not?

A. Yes, it is.

Q. That shows that to be the pink—I mean the yellow to be in the highest pressure area in the field, does it not?

A. According to the interpretation of that map I would say yes.

Q. Yes. Well, do you recall a Federal Power Commission map—if it doesn't show also that the Canadian

River area is situated in the higher pressure area of the field?

A. The higher, yes, but not the highest.

Q. That's right. When I say "your map," I refer to Exhibit 179. Well, it shows this area that I am pointing to here which is the Canadian River to be—much of it to be over four hundred pounds, does it not?

A. Yes, that is right.

Q. As a matter of fact, you run out even beyond four hundred, do you not?

A. That's right.

Q. All right, now, if you were to shut in every well in the field, what would happen to the pressures in that field?

A. Well, there is a big element comes in there.

Q. Just forgetting about the time element.

A. Now, wait a minute. I am answering the question. It would eventually have a tendency to equalize if given time enough.

Q. You say "tendency." Wouldn't it equalize?

A. If given time enough, yes.

Q. We're together on that. It would equalize, disregarding the time element. You mean by that that you don't know how long it would take, is that it?

A. Well, it would take a long long time.

Q. But you don't know how long and nobody else does.

A. And nobody else does.

Q. It would equalize. That fact is certain.

A. Eventually.

Q. That's right. Now, what do you mean by "equalize," Mr. Hammer?

A. Well, just as the term indicates so that the pressure would be equal.

Q. That means the gas from the high pressure areas would migrate into the low pressure areas until the gas in the two pressure areas were the same?

A. That's what equalize would mean.

Q. All right, now, we'll go ahead. Now we are assuming that all of the wells are shut in. The gas in the yellow area would first migrate to what area?

A. Well, part of it might migrate into that lower pressure area.

Q. The next—

A. No, I am talking about that other low pressure area you have got in the other part there.

Q. Over here (indicating)?

A. Yes, that's right.

Q. All right. The general movement would be where?

A. The general movement would be to the north and northeast.

Q. To the north and east. All right, we come up to this next pressure and which is the pink one, and what would be the movement out of that band?

A. In general it would be the same as the band we just described.

Q. That's right, and on and on and on and finally much of this gas would find its way over to Borger, wouldn't it?

A. Well, that is a question that is open to argument.

Q. What is the argument about it?

A. Well, a lot of it would never reach Borger.

Q. That's right, it would reach equilibrium before a lot of it reached there, wouldn't it? Isn't that right?

A. Well, now, that word "equilibrium," that is using another term.

Q. All right, what do you want to use—"equalize"?

A. No.

Q. All right.

A. I simply want to state that the intervening wells there would capture—use the word "capture"—a large percentage of that gas before it ever got over to Borger.

Q. If the wells were shut in.

A. No.

Q. I said if the wells were shut in.

A. Well, eventually, yes, it would go to the low pressure area.

Q. That's right, and keep going until that hole over at Borger was filled up, wouldn't it?

A. That's right.

Q. Now, will gas migrate more rapidly where the pressure bands are narrow or where they are wide?

A. Do you mean where the pressure differential between two of your isobars where it is narrow—

Q. Let me restate it, if you prefer it that way:

Will gas migrate more rapidly where the pressure differentials are high or where they are low?

A. Well, that is a question that is controlled—well, they would have that tendency, but the actual performance would depend in its entirety upon the permeability of the producing horizon at any given area under such a condition.

Q. All right.

Mr. Spencer: I don't believe the record is clear there. You say, "would have that tendency." I don't believe the record will be clear what you mean by a tendency—a tendency to what?

The Witness: Well, we were talking about migration. It would have a tendency to migrate more rapidly.

Mr. Spencer: That's right.

The Witness: Over areas of short horizontal pressure differentials than over wider areas, but the point I want to make there is that that thing is controlled very largely or at least to a considerable extent by the permeability of the producing horizon.

By Mr. Keffer:

Q. All right, do I understand that you mean that the more permeable the formation the more rapidly the gas will migrate?

A. Yes, that in general is true.

Q. Then does not wide pressure bands indicate a high degree of permeability?

A. No, not necessarily.

Q. Why wouldn't it?

A. Well, because a lot of those—a lot of that area is—it is dropping in pressure, it isn't dependent on migration at all except locally. It is dependent upon development that has taken place there, not some place else.

Q. How do you know that?

A. I know development occurred there.

Q. You also know that drainage has occurred, don't you?

A. We also know that drainage has occurred to reduce the pressure locally. For instance, out there in central Moore County, that low pressure out in there isn't due to any migration of gas over to the Borger area, it is due to

the migration—it is due to the gas that has been taken out of those wells locally.

Q. That is quite true. That is very true, but on the other hand where you do have the pressure differentials which exist in here and you have just said that if the wells were shut in there would be a migration of gas over to the Borger area, didn't you?

A. Yes, but we aren't dealing—have we got away from this shut-in yet?

Q. Not yet. We'll get away from it in a minute, but not yet.

A. I doubt very seriously, in fact, there wouldn't be anything to justify a statement that if the whole field were shut in there would be very much effect, we'll say, over in the central part of Moore County.

Q. I am not talking about Moore County. I am talking about Hutchinson County.

A. Well, you are talking about drainage, aren't you?

Q. Yes, but Hutchinson County. Just direct your statement to the thing I am talking about.

A. That's just the thing I was talking about.

Mr. March: He is explaining drainage. I realize you want the gas to move the other way.

By Mr. Keffer:

Q. You stated a while ago that it would move into the Borger area, didn't we? Do you want to take that back? Do you want to change your statement on that?

A. Well, in a closed-in condition which is an assumption that does not exist, and never will exist—

Q. Well, we have had shut-ins on a lot of wells in Texas. I have heard a lot about them.

A. It is purely hypothetical.

Q. Indulge me in that way, in that respect. The wells are all shut in, the gas is moving toward Borger. Do you still want to say that? You can change your answer if you want to.

A. No, if you would give it ample time, eventually it would equalize.

Q. All right, let's stay on Borger. We'll give you a chance to get into Moore County if you want to go up there after a while.

A. I have no desire to go up there.

Q. Those wells are shut in—I will restate it again. There is a general movement of gas into the Borger area from the southwest. That is right?

A. Under closed-in conditions.

Q. That's right.

A. You would also have it from the northwest.

Q. Answer me, if it wouldn't have moved from the southwest?

A. I said, "also," which means that you would have.

Q. I haven't asked you about the northwest.

A. I know, but I told you.

The Trial Examiner: We'll stand in recess for five minutes.

(At this point a short recess was taken, after which proceedings were resumed as follows:)

The Trial Examiner: The hearing will be in order.

Mr. March: May I ask one question here, Mr. Keffer?

Mr. Keffer: Yes.

Mr. March: Mr. Hammer, have you prepared an exhibit which shows drainage in the Panhandle field?

The Witness: Not with any particular reference to drainage, no.

Mr. March: Did you make any detailed careful study of the whole drainage problem—detailed problem of drainage in the preparation of your exhibit here, Exhibit 180 and Exhibit 186?

The Witness: No, I did not.

Mr. March: Do you feel that if you are going to testify in regard to the details of drainage that you would want to make a very careful study of that problem?

The Witness: Yes, I would.

Mr March: And which study you have not made?

The Witness: I have not made any particular study particularly in relation to this exhibit here. I would like an opportunity to go over that thing pretty thoroughly.

Mr. March: Before you would make any statement in regard to it?

The Witness: Before making any statements, that's right.

Mr. March: I think that is clear to Mr. Keffer and to the Examiner that the witness at least has not come up here to testify in regard to a drainage exhibit which is fundamentally an exhibit in regard to that, and it is unfair to cross examine the witness about that at this time.

The Trial Examiner: Mr. March, I don't intend to require Mr. Hammer to testify to something that he is not familiar with.

Mr. March: He is only familiar with this in a general way, and if he is going to be cross examined about the drainage he should make a careful study about it and come back here and be cross examined about it.

The Trial Examiner: I understood the other day that there was an exhibit to come in.

Mr. March: There may be an exhibit to come in. That has not been prepared. There was a mistake made about that in the record. It was my fault I think, because the way I saw this thing the whole case of the opposing side here as I see it offhand is that they are going to show that this whole field is going to blow up like a *baloon*, therefore, this drainage problem come in and plays an important role. Now, it may be that we will prepare and make a careful study of their exhibits and after that and studying the whole drainage problem, we may offer an exhibit. We haven't got one prepared now. The witness has not made a careful study of drainage in regard to these exhibits which he is offering here and I feel that when one of the geologists goes on the stand that he should be cross examined at least about the exhibit which he has prepared, not about something entirely different.

I don't feel that Mr. Hammer should be required to testify in regard to—especially in regard to a hypothetical exhibit like this, a hypothetical situation like this, on the spur of the moment without any preparation, without any study, just come in here and be asked "What do you think

of this?" on a bunch of hypothetical questions on drainage that doesn't pertain to this exhibit he is offering at all. It is unfair to the witness.

I will go one hundred per cent on everything and I believe I have, Mr. Keffer, but to take his exhibit and have a preview of his case through our witness, why, that is something that I don't feel that Commission's counsel can take the responsibility of insisting that the witness go ahead with.

Mr. Spencer: Mr. Examiner, this is very simple. All the witness has to do to stop this line of cross examination is to say, "I want to study that; I am not prepared to answer." That is all there is to it.

Mr. March: He has already said that.

Mr. Spencer: If he isn't prepared to answer questions on drainage, let him say so and we will stop. That is all there is to it.

The Trial Examiner: Well, let's go along to specific questions and if Mr. Hammer can't answer and doesn't feel that he can answer, he may say so. He is not required—I haven't required Mr. Hammer or directed Mr. Hammer to answer a question that—

Mr. Spencer: And certainly, Mr. Examiner, we don't want him to answer on anything that he isn't prepared to back up.

Mr. March: Here is the thing: When a man comes up here and introduces an exhibit on which he is prepared to answer and then he is required to answer questions on another exhibit which he hasn't studied carefully, why, naturally he is extemporaneously speaking and there are possibilities that the witness might make a mistake, and we wish to interpose the objection again. We feel that it is a serious proposition.

Mr. Keffer: If it would help Mr. March any, I don't know, I think much of it originated because I put the colored map up there, Mr. Examiner, and it is a little more tedious. I can go over the same ground with Mr. Hammer's map which shows identically the same thing.

Mr. March: All right, if you want to cross examine him about his own exhibit, that's all right.

The Trial Examiner: Now, Mr. March, I am not going to limit the cross examination to Mr. Hammer's direct examination: I haven't done it so far in this hearing and I don't intend to do it now.

Mr. March: I don't intend for you to.

The Trial Examiner: If this question of drainage comes up here and is illustrated by this particular map, I think it would be much more beneficial to all of us to visualize what they are talking about. Now, if Mr. Hammer can't answer, that is a different proposition. All he needs to do is to say so.

Mr. March: Do you know what this is, Mr. Examiner? This is really—by all fair procedure this exhibit should be put on by a witness. Let him testify as to his theory of drainage, whatever it is, and then if they want our witness to say what he thinks about it, they can ask about it, but here we come up with a map we don't even know who prepared. We don't know whether it is correct or not. We don't knew anything about the map. We haven't got a witness here who offered the map.

The Trial Examiner: Let's go along. Mr. Keffer hasn't endeavored to verify his map through Mr. Hammer.

Mr. Keffer: I think we will get along much faster if we just take this map down.

Q. Mr. Hammer, we were discussing a while ago what would happen to the gas in the Canadian River area, particularly, if all of the wells in the field were shut in, and you answered, I believe, that it would migrate northeastwardly toward the low pressure areas around Borger.

A. Now, I want to explain that situation a little bit.

Q. All right.

A. I believe I stated—if I didn't, I'll state it now—that one of the fundamental things in gas movement is pressure differentials. Now, distance is quite a factor in the movement of gas. Time is also a factor in the movement of gas. Gas will move more rapidly at areas of greater pressure differential. Now, as your pressures start to equalize under

your hypothetical setup, there would be a less and less tendency all the time for gas to migrate any considerable distance, and the most rapid movement would be during any of the time—would be at the point of greatest pressure differential. You must take into consideration the distance and variables in pressure differentials.

Q. Yes, that's right. Are you through?

A. For the present.

Q. Yes, all right. Now, the present pressure differentials you speak of do exist as shown by your isobar contour lines, all the way across there, don't they?

A. But you must—the differentials are local. Now if you will step back from those, you would have a less and less gas movement and as distance came into the picture, might eventually reach a point—as you reached the point where the field, for example, had almost equalized and your differential from one point to another became less and less and approached zero, you very probably would reach a point where, because of the condition of the sand and the permeability, particularly permeability, it might take almost an indefinite, inconceivable time for the thing to completely equalize.

Q. All right, let's get down to answering specific questions, if you please, Mr. Hammer.

Now, you stated a while ago that gas would move more rapidly through a highly permeable formation than it would through a formation of less permeability, didn't you?

A. Yes. If you have a similar pressure differential.

Q. If you have the pressure differential. Let's take a very crude—a very simple illustration. Let's take a large tank the size of this room, or the size of this court house, and let us fill it with water—or let us fill it with gas to make a more analogous situation. You put a pipe line over in one side of that tank, just one side of it, and you start taking gas out of that tank. What happens to the gas in the tank?

A. Well, that is not an analogous situation at all.

Q. Wait a minute. Answer my question.

A. I am going to answer it.

Q. No, you're not.

A. Yes, I am.

Q. I'm going to insist that you answer it.

A. I'll answer your question but I'll answer your question in my own way.

Q. Go ahead, then.

A. That isn't analogous of any underground situation of which you can conceive.

Q. Won't you let me develop it step by step? I know it is not. I am not that dumb.

A. All right, go ahead.

Q. All right. When you take that gas out of one side of that tank you get all of the gas, don't you, through that one pipe on one side?

A. Well, under a condition like a room here.

Q. Yes, that's what I'm talking about.

A. But as I stated, that is not comparable at all.

Q. I'll grant you that. Let's forget about that for the moment. Suppose that tank represented the whole Panhandle field, it was that large, and you had one pipe taking it out over here at Borger, what would happen to that entire field?

A. Probably two or three million years from now it might eventually equalize.

Q. If it was in a tank.

A. If it were in a field.

Q. I said in a tank representing the size of this field.

A. Well, if it were a tank, yes, it would equalize.

Q. That's right, it would equalize with very little pressure differential, wouldn't it?

A. In an open reservoir, yes.

Q. That's right, your pressure on the southwest side of that tank would not be more than a few ounces higher than it would be on the other side of that tank, would it?

A. Well, it would probably be the same.

Q. There wouldn't be enough that you could measure the difference?

A. In an open tank.

Q. Why? You have your one hundred per cent permeability there, don't you?

A. Yes, that's right.

Q. You have no restrictions to the flow of that gas from one side of that huge tank the size of this field to the other side of the tank, do you?

A. No.

Q. All right, now, let's build a dividing line in that tank

with very minute pores—very minute, porous spaces, and then take gas out over in the Borger area. If your pore spaces are fine enough you are going to have a pressure differential, aren't you?

A. Yes, as between the two.

Q. That's right, as between the two. Why is that?

A. Well, you have set up there a hypothetical factor that deals with a question of permeability.

Q. That's right, you have an obstruction there through which the gas will not travel as rapidly as it would if it was one hundred per cent void, haven't you?

A. That's right.

Q. That is it, precisely. All right, now, the greater that obstruction, the greater will be your pressure differentials on one side of the tank and on the other side, won't it?

A. You mean the more effective that that barrier would be?

Q. All right, let's take extreme cases all the way through.

A. Well, I think I answered your question.

Q. All right, we'll put a barrier through there that is absolutely impervious; that is, gas won't migrate through it at all; then your pressures over on this side would remain at 430 pounds, if that is what you start with, wouldn't it?

A. Yes.

Q. And you take all of the gas—you can take all of the gas out over on the Borger side, wouldn't you?

A. That's right.

Q. That's right. Now, if you open that up just a little bit, have just a few porous spaces through there, where just a little gas can get through and you keep taking it out over at Borger, you are going to have an increasing pressure differential, won't you?

A. No, you would have a decreasing pressure.

Q. All right, let's make the porous spaces through the center of that tank such that when you are down to a hundred pounds at Borger you are only down to 400 pounds over here in the southwestern part of the field in the Canadian River area. You have a great pressure differential there, haven't you?

A. That would be true.

Q. Is that right?

A. That is right.

Q. But gas is moving rather slowly because of the per-

meability, if you please, of that obstruction that you have through the center. Now, isn't that right?

A. Yes, that would be the case.

Q. All right, we'll punch more holes in that, increase its permeability, then what happens to your pressures?

A. Your pressure differential would become less.

Q. That's right, the gas would come out of this western part still faster, wouldn't it?

A. Under that hypothetical condition, yes.

Q. That's right, and there would be less difference between your pressure bands on the two sides of that obstruction, wouldn't there?

A. Yes, that is right.

Q. All right, punch more holes in it and gas goes out still faster. You are still reducing the difference in pressures on the two sides of that obstruction, aren't you? You are getting less and less? Less and less differential?

A. That's right.

Q. Is that not correct?

Mr. March: You mean assuming the thing is shut in?

Mr. Keffer: No, it is going out over here all the time. It works either way. It doesn't matter.

Q. All right, now, we started with a hundred per cent permeability and lost all of our gas through the Borger area, through the pipe line leading out of the big tank over there with a hundred per cent permeability, didn't we?

A. Yes.

Q. And no pressure differential at all?

A. Under your hypothetical case, yes.

Q. All right, then, we put an obstruction in there and we did reduce the permeability from one hundred per cent and we held some of the pressure over here—or, first, we put one through there that no gas could get through at all, had no permeability and lost nothing, that is right, isn't it?

A. That is what you stated.

Q. Then we started punching holes in there. The more holes we punched in it the more gas we lost, didn't we?

A. That's right.

Q. And the more holes we punched in that obstruction the less pressure differential we had on the other side of that obstruction, didn't we?

A. That is true.

Q. All right, then, doesn't it follow unavoidably that the greater your permeability, because we were increasing permeability every time we punched another hole in that, the greater your permeability, the less your pressure differential and the greater your drainage?

A. No, that is not true at all.

Q. Why isn't it?

A. You are disregarding entirely the question of distance.

Q. Tell me, why isn't it true?

A. You are disregarding entirely the question of distance and you are disregarding—I don't like to talk about hypothetical cases.

Q. The distance was just the same as on that field. We had assumed that.

A. You just put a barrier in there. That wasn't—

Q. The size of that Panhandle field.

A. That barrier of yours might have been the width of a sheet of paper or a hundred feet thick or five miles, you didn't state that.

Q. We'll state that—we'll put barriers in there all the way along, all the way across that field, every one an impervious barrier, then start punching holes all the way through those barriers, you are increasing your permeability, aren't you?

A. You are increasing the permeability, that is true, when you make more holes.

Q. All right, you are increasing your drainage, aren't you?

A. Yes.

Q. And you are lowering your pressure differential, aren't you?

A. That is right.

Q. Absolutely. All right, now, get back to the statement I made a moment ago, the greater your permeability the more rapid your migration and the less pressure differential you will have. I don't care what the distance is.

A. Well, of course, you increase your permeability and naturally you have an increase in flow.

Q. All right, and if you had that portrayed out on the map, the wider your pressure bands would be, wouldn't they?

A. Had what portrayed on the map?

Q. Just as you have your isobar lines on your map.

A. Now, I don't get your question exactly. What do you mean?

Q. All right, we have already agreed that the greater your permeability the greater—or the more rapid is the migration of gas from a high point to a lower point, even though the pressure differential is slight. If your permeability is there you are going to lose that gas with a minimum of pressure differential, if you have got your permeability.

A. Assuming an ideal condition, you might say, yes.

Q. Well, assuming any kind of a condition. Remember I said if you have permeability.

A. Well, you always have some permeability, naturally.

Q. I know, but the greater your permeability the greater your loss, isn't it?

A. The greater your permeability under equal pressure differentials.

Q. All right, the greater your loss.

A. The greater would be your flow.

Q. You can have greater loss of gas by drainage through a highly permeable formation with only ten pounds differential in pressure drop than you can have through a tight non-permeable formation or a formation with low permeability even though you may have sixty pounds pressure differential?

A. Well, I wouldn't answer that.

Q. I want you to answer it.

A. Well, I don't want to answer it. I am not prepared to answer it.

Q. Well, what preparation do you need to answer that?

A. I want to think it over.

Q. How long do you want to think it over?

A. Oh, tomorrow morning.

Q. You think you will have an answer then? Will it be all right if I ask you that question tomorrow morning?

A. You can ask it tomorrow morning.

Q. Will you promise to answer it then?

A. I will do my best.

Q. All right. I want to be sure. I don't want to lie awake figuring on this question if you aren't going to answer it.

All right, now, I think we have illustrated pretty well the part that permeability plays in drainage, don't you?

A. Well, it is somewhat illustrated, yes.

Q. All right. Now let's go to another phase of this thing. We are talking—we were talking a while ago about what would happen to the reservoir or to the field if all of the wells were shut in and producing no gas. Now, you didn't much want to answer that on the theory that isn't the case, that wells aren't shut in, they are producing gas; but let me ask you this:

With all of those wells producing as they are today and as they have been for some time past, this pressure differential has been created and continues to exist, is that not right?

A. Naturally you have to have pressure differential or you wouldn't have pressure at your wells, or you wouldn't have any flow.

Q. That's right, that's just at the well bore, but we have wide areas through that field represented by pressure differentials as shown by your map, your isobar contour lines show that beyond any question.

A. Oh, yes; there are pressure differentials there.

Q. That's right, and what has caused that pressure differential?

A. Gas withdrawals.

Q. That's right, heavy withdrawals along the northeast flank of that structure, isn't it?

A. That's true.

Q. And heavier on the northeastern flank relatively than on the southwestern flank, isn't it?

A. Heavier on the northeast.

Q. Relatively than on the southwestern per acre? Please state it that way.

A. Well, I'm just trying to get my geography.

Q. When I say "northeastern," I mean the northeast section of that reservoir, the northeast flank.

A. Well, I think we have already agreed there is no gas out there.

Q. I mean within the gas producing area as you have outlined it here.

A. Well, yes, the pressure differential also extends from the area to the northwest. It also extends—

Q. I know, but will you please answer my question, Mr. Hammer?

A. I am answering the question.

Mr. Keffer: Read the question, Mr. Reporter.

(The question referred to was read by the reporter, as set forth above.)

By Mr. Keffer:

Q. Now, can you answer that simple question?

A. You are talking about the northeastern flank of the entire fold?

Q. That's right.

A. That's right, I didn't understand you.

Q. And the gas withdrawals have been heavier along the low pressure areas existing along the northeast flank than it has been back farther to the southwest?

A. Yes, that is right.

Q. And that has caused these pressure bands, hasn't it?

A. Yes, that has caused your pressure differentials.

Q. All right, now, you started to state a while ago that there had been heavy production up in the north part. What did you want to say on that? I wanted this other question answered first.

A. What was your statement?

Q. You started a voluntary statement, not in answer to my question, and I wanted to give you the opportunity to state what you had in mind. What did you want to say on that?

A. Well, that came about by misunderstanding of what you were trying to get at in the succeeding question.

Q. Yes.

A. Now since we have understood and decided you meant as between the two sides of the field, why, then I don't have any statement to make.

Q That's all right. I wanted to give you an opportunity to state what you had in mind.

A. I didn't have anything in mind after we got that straight.

Q. All right, now, as a matter of fact, if gas had not been migrating from the southwestern to the low pressure areas in the Borger area, you wouldn't have had these pressure differentials ranging out to the southwest, would you?

A. No, nor I wouldn't have them to the northwest or locally there at the southeast.

Q. That's right, if there wasn't a migration of gas every place you have a well, you have a local low, just a circle around that well, and go over to another one, and just a circle around it, you would have a series of circles around that field, if no migration of gas except locally to local well bores, isn't that a fact?

A. You would have a condition similar to the condition that has developed and is developing up through central Moore County.

Q. All right, and instead of having—you mean you have two or three local lows?

A. That is right.

Q. Instead of having two or three local lows you would have two or three thousand local lows if there was no migration of gas from the general high pressure area to the general low pressure area?

A. No, I don't agree with that statement.

Q. Well, what's wrong with it?

A. As I said a while ago, you are trying to move gas in mass over long distances.

Q. No, I'm looking at a picture which you have drawn yourself.

A. So am I looking at that picture, and where is your rapid pressure differential? It is right there in the vicinity of Quadrant 1, Hutchinson County. Now, when you get away from that a very short distance, that rate of pressure differential rapidly changes and it flattens out, more or less, into a low—

Q. Wait a minute.

A. I haven't finished.

Mr. March: Let him finish his answer.

The Witness: It flattens out into a local condition extending from approximately here on (indicating).

Mr. March: Which way?

The Witness: To the west.

Mr. Lange: In Moore County?

The Witness: In Moore County. In other words, taking in approximately the center of Quadrant 1 in Moore County and a little piece of the center of Quadrant 6 in Moore County. From there on west the pressures have almost

flatténed out. Your movement of gas is dependent there in that case upon your local pressure differential from here on east (indicating).

Mr. March: Where on east?

The Witness: Well, from about the center of Quadrant 1 and Quadrant 6 in Moore County over towards the Borger area.

By Mr. Keffer:

Q. And over into the Borger area?

A. That's right, but it only extends into about the position of this here (indicating).

Mr. March: Which here?

The Witness: Into the position of the center of Quadrant 1 and Quadrant 6 in Moore County. The drainage is over in this part of the county due to gas withdrawals on the southwestern part, being taken out of there, and still being taken out.

Mr. March: The western part?

The Witness: The western part of Moore County.

By Mr. Keffer:

Q. How do you know that?

A. Well, I know it from my study of the pressure isobars over the period of the last five years in the construction of the maps.

Q. All right, I thought we just agreed after lengthy argument, almost, a while ago, that the greater your permeability the wider the pressure bands and the less pressure differential you had, didn't we agree on that?

A. No, I don't think we—as I understand you now, we did.

Q. How do you understand me now as compared to how you understood me then?

A. I don't know what you are driving at right now. You seem to be—

Q. Have we got to go through all that again?

A. I don't care if it takes a week.

Mr. Keffer: I don't either.

The Trial Examiner: I think, gentlemen, that the record, of course, will speak for itself and perhaps Mr. Hammer did not understand at the time of his previous answer, but my understanding of your response to Mr. Keffer was exactly the same as Mr. Keffer states it, and if that was incorrect, let's correct it and start over.

The Witness: Exactly as his statement concerning what?

The Trial Examiner: The statement he just made.

The Witness: What was the statement he just made?

(The record referred to was read by the reporter as set forth above.)

The Witness: Well, I think that the explanation I made there of the flattening out of those isobars explained that. It automatically shows a flattening of the pressure as you get away from the Borger area.

Mr. Keffer: Well, all right.

Q. Take the pressure bands which you have which is depicted on your map, on 179, and it shows a rather rapid decline in pressure between a point, we'll say midway, approximately, of Quadrant 3 in Hutchinson County and Quadrant 1 in Moore County, doesn't it?

A. Yes, locally that is true, in that area.

Q. All right, now, take your production over in Hutchinson County, has it been at a higher rate or a lower rate than the production out in immediately to the west in Moore County?

A. I believe that it has been at a higher rate.

Q. Higher rate, that's right; otherwise, you wouldn't have those pressures, isn't that right?

A. That is right.

Q. That is the thing that makes them.

A. That's right.

Q. All right, let's take a situation—let me ask you this: In your study of this field you studied your pressure declines primarily in making your estimate of gas reserves, didn't you?

A. We studied our weighted pressure decline.

Q. All right, did you find an area in Hutchinson County

in which the pressures generally were increasing in the wells in that area?

A. Over a five-year period I found no place where they were increasing but a local area where over the five-year period the pressures remained approximately static.

Q. Did you find any in the last three or four years in which they were increasing substantially as much as twenty pounds—twenty-five pounds?

A. No.

Q. You didn't find any of those?

A. No.

Q. Suppose you had found some of those, what would that have indicated to you?

A. Well, it might indicate several things. When you go to dealing with the pressure of an individual well,—

Q. I am talking about a group of wells in an area, not just one well.

A. You mentioned a well.

Q. I will change that, then, to a group of wells in an area.

A. Well, you would assume, of course, that in this group of wells that you are talking about there would be somewhat of an increase of gas to those wells.

Q. Of course, that is obvious, isn't it?

A. Sure.

Q. How do your suppose that gas got there?

A. Well, it probably migrated there from—not—

Q. Well, suppose, though, during all that time we are producing substantial volumes of gas, would that indicate anything to you?

A. Well, it all depends on the area you are considering.

Q. Well, any area.

A. All right. You know, of course, that there has been in that Borger area some repressuring?

Q. That's right. Yes, I know that, and that is the reason I am asking you these very questions.

A. Now, that repressuring automatically, while it was going on, at least—I don't know whether it is still going on or not—but while it was going on it automatically increased the pressure on the wells around close to it; that is, where the wells were utilized to put the gas into the ground.

Q. That's right, and that repressuring was going on while those wells in the Borger area were producing large volumes of gas.

A. Well, I don't remember now exactly when it was going on but I knew that did do some repressuring.

Q. You never knew any of them cutting down production particularly in the Borger area, did you; that is,—or, shutting them in,—I'll state it that way. They did cut it down some.

A. No, I think they are still producing.

Q. They are still producing and they were still producing during that time and today more gas per acre in the Borger area and Sanford area than they are in the Canadian River, aren't they?

A. Yes, that is true.

Q. All right, now, if they are producing that large volume of gas in the Borger and Sanford area, that general area of Hutchinson County, producing more gas per acre than they are out in the Canadian River area and in spite of that pressures are increasing or at least aren't decreasing, what is the only possible explanation for that phenomena?

A. I will answer that by a qualification. You are attempting to paint a picture here that all of the gas that is going into that Borger area comes from Canadian River acreage.

Q. No, no, I am not doing any such thing.

A. Why not mention the fact then, that it is coming in from the north and west.

Q. All right, where is it coming from?

A. The pressure isobars indicate where it is coming from. It is coming from the north, if it is coming at any particular rate. It is coming from the north, it is coming from the northwest and it is coming from the west.

Q. How about the southwest?

A. Well it is also coming from the southwest some.

Q. The whole point is, Mr. Hammer, that that gas into that area, at least, is necessarily migrating long distances, isn't it?

A. No, that is not true at all.

Q. All right, take the wells to the north and the northwest and the west and the southwest and you have heavier

production of wells in that area than you have back in Potter County and in Moore County, now, isn't that a fact?

A. That is true.

Q. All right, if that is true—

A. That is just the point I make.

Q. All right, fine.

A. If you have wells, say, up here in the northwest part of Quadrant 3 drawing gas out up there—

Mr. Lange: What county?

The Witness: In Hutchinson County, those wells locally there, are the reason why you get that pressure differential. It is not this area down here (indicating).

By Mr. Keffer:

Q. All right, how do those wells up there locally make that pressure differential?

Mr. March: What he means is down over here (indicating).

The Witness: I mean the Borger area.

By Mr. Keffer:

Q. Be more specific as to the pressure differential caused by production in the northwest part of your Quadrant 3 in Hutchinson County.

A. Well, I happen to know that there are wells up in there producing gas.

Mr. March: Quadrant 3, Hutchinson.

The Witness: And I happen to know that right across here in Moore County that there is a low pressure area. There has been a low pressure here for a long time. Now, the wells are taking gas out in there.

Mr. Lange: Where? Be specific.

The Witness: Just in this Quadrant 3, just across into Moore County, are the wells that are responsible for that pressure differential. It is not long migration down through to the Borger area.

By Mr. Keffer:

Q. The area you are talking about is a low pressure area. All right—as shown by your map, isn't it?

A. Yes, that is right.

Q. All right, now, certainly those wells from that area aren't feeding the Borger area, are they,—they couldn't be?

A. No, that is true.

Q. Of course not. We have eliminated the northwest part of your quadrant, haven't we?

A. Wait a minute. We haven't either.

Q. All right.

A. You come out this side and you still have a pressure differential.

Mr. March: Quadrant 3, Hutchinson?

The Witness: Quadrant 3, Hutchinson County. You come over here in Quadrant 4 Hutchinson County and you still have a pressure differential coming down into your Borger area.

By Mr. Keffer:

Q. Those pressures running back this way—

Mr. March: "Back this way," which way do you mean, Mr. Keffer—northward?

Mr. Keffer: Yes.

Q. All right, maybe we have spent enough time on that. Let's summarize a minute. You have wells in an area in Hutchinson County in which pressure is either holding its own or increasing somewhat, wells around it producing large volumes of gas and the gas is coming from somewhere to repressure those low pressure areas.

A. Yes and in a condition like that it is just as apt to be coming from pressure differentials in local areas, more apt to be than it is from long distances.

Q All right now, when you say "those local areas," you mean near by?

A. Near by.

Q. All right, if those nearby areas are themselves producing large volumes of gas, then the chances are they are just catching some of it as it goes by, isn't it?

A. Well, they have an effect, of course, on pressure, and they also, as stated, they capture a lot of the gas if it has a tendency to migrate back.

Q. That's right, and there is nothing as shown on your map or any other map that I have ever seen that would indicate that the acreage near by those areas that are being repressured is furnishing the gas for that repressuring?

A. I don't agree with that. I want to call your attention to just one thing here.

Q. All right.

A. Right up here in this part (indicating).

Mr. March: Now, be specific as to the designation, because the record won't show what you are pointing to if you don't.

The Witness: All right, Quadrant 6, Moore County, prior to 1939 there had been no wells drilled in this immediate area.

Mr. March: Which area is that?

The Witness: The southwest corner of Quadrant 6. There were some wells drilled in there in 1939. Prior to that time, because here was a low pressure area and some wells here—

Mr. March: Where is that?

The Witness: Along the eastern side of Quadrant 6, Moore County, and there were producing wells as far as Quadrant 6, Moore County, with no intervening wells. The only thing you could do was assume a gradual slope because you had no other data.

All right, in 1939, four wells were drilled here. I will give you the names of them. Now, after these wells came in I didn't have the pressures on the wells so a letter was written to the Texas Railroad Commission under date of March 20th, 1940 and they gave the names of these wells and their closed-in pressures. The wells are the O & H—no. the Panhandle Eastern, J. T. Sneed in Section 1—Sneed 1 in Section 3—Exhibit 95—In Section 3 on the O & H Lindsay Survey, Moore County. That well had an initial rock pressure of 350 pounds, completion date of September 19, 1939.

The other well is also on the Owen H. Lindsay Survey in Section 4—

Mr. Lange: What County?

The Witness: Moore County. That well was completed on October 11, 1939 with a pressure of 332 pounds.

The next well was the Shamrock Oil & Gas Company's J. T. Sneed, Sections 1 and 2, on the Joseph H. Johnson Survey in Moore County. That well came in on September 10, 1939, with a pressure of 370 pounds.

The last one was the Texamo Natural Gas Company's J. T. Sneed, 21-P in Section 72—I think that is Section 72,—the G & M, Block B-3, Moore County. That well had a pressure of 321 pounds.

Now, the point is that although there had been apparently greater distance extending into the low pressure area, the Moore County-Hutchinson County line, here was a well drilled in 1939 in Quadrant 6 that had a pressure of 50 pounds higher than wells to the west, which seems to indicate that a drainage in the past and drainage even now is not all in that direction.

Mr. Keffer: Let me ask you a question with respect to that, Mr. Hammer.

Q. Those wells that you have referred to were drilled in a larger area in which no wells had been drilled previously, that is correct, isn't it?

A. That is true.

Q. You had some pressures that were down to 320 pounds or 323 pounds, I believe, one of them—

A. That is right.

Q. And what is the pressure of one of the others?

A. The lowest was 321 pounds.

Q. 321 pounds?

A. Yes.

Q. That area had lost how much gas?

A. What?

Q. That well had lost how much gas up until it was drilled?

A. I don't know how much gas was lost. I know what the pressure drop was.

Q. All right, what was the pressure drop?
A. You mean from the original field pressure?
Q. That is right.
A. Well, it was 109 pounds.
Q. For all intents and purposes that is one-fourth of all of the entire gas that was there originally?
A. One-fourth of the original pressure.
Q. Wouldn't that be a fourth of the original amount of gas to zero, and not to your 25 pounds?
A. Well, I—
Q. Let's get at it this way: Your original pressure there was 430 pounds?
A. I assume it was.
Q. Haven't you made that assumption all over the field? You say so in your statement.
A. Yes, I assume it.
Q. You lost 109 pounds, didn't you?
A. That is right.
Q. That is more than a fourth of 430 pounds, isn't it?
A. All right—
Q. Wait a minute.
A. I am agreeable to that and in that same list—
Q. All right.
A. —you had a well with a 50-pound pressure and wells to the west.
Q. We will come to that in a minute. There is a tract of land that had never had a well on it—
A. No, it hadn't been drilled previously.
Q. It was the first well on the tract?
A. That is right.
Q. You drilled into that formation and found that more than one-fourth of your gas had gone somewhere, didn't you?
A. That is right.
Q. Where did it go?
A. It went to the closest well that could drain it.
Q. What were the closest wells that could drain it?
A. Well, I would have to check on that.
Q. All right.
A. These wells in this area over here in Quadrant 6, Moore County, would be one of them.
Q. In which portion?
A. Along the southeastern line.

Your next closest well to that would be slightly over a mile.

Q. What was the name of that well?

A. I was just going to give it to you.

Q. All right.

A. It was the Texoma Natural Gas Company, J. T. Sneed, 21-P, Section 17, G & M Survey, Block GM-3.

Q. All right, that is the well we are talking about?

A. Yes. Section 72 is correct.

Q. The question is, "Where did the gas from that well go?"

A. The closest well was down here about a mile and a half. It is on the Charles Ragsdale Survey in Moore County.

Q. All right, what is the pressure of that well? I believe the map shows it to be above 330 pounds. If that is true it couldn't have drained to that well, could it?

A. I couldn't read them off of this map.

Q. Let it go. Maybe we can straighten that out later.

The Trial Examiner: What did you say, Mr. Keffer?

Mr. Keffer: Just let that go. Maybe we can figure it out a little later.

Mr. March: Mr. Hammer will get that information for you, Mr. Keffer.

Mr. Keffer: That is all right.

The Witness: I can get the information for you but I can't tell right now.

Mr. March: Is that the Texoma well you are referring to?

The Witness: No, not this one. However, I am not sure of that because I can't check it from this map.

The Trial Examiner: You are sure of the well, Mr. Hammer, that Mr. Keffer asked about?

The Witness: Yes, I know the location of the well.

By Mr. Keffer:

Q. What is the next low pressure of the three wells you gave?

A. The next lowest pressure was 332 pounds.

Q. All right, that is the Panhandle Eastern, and where is it located?

A. No, that is the Shamrock Oil & Gas, J. T. Sneed 16.

Q. Will you locate that for us on the map? Can you state the location of it?

A. That well is in Section 4, the center of Section 4. It is on the Owen H. Lindsay Survey, Moore County, Texas.

Q. That acreage is demonstrated by the original pressures on that well having lost virtually a fourth of all of the gas that was there to start with?

A. Yes, approximately.

Q. In fact, more than a fourth, if you consider the 25-pound abandonment pressure?

A. It had—

Q. Wait a minute. Hadn't it?

A. It had lost—

Q. More than a fourth if you would consider the 25-pound abandonment pressure?

A. That is about right.

Q. And it had never produced a foot of gas, had it?

A. No.

Q. It had lost it all by drainage, hadn't it?

A. Yes.

Q. Where had it drained to?

A. The closest well to the west, being about two miles.

Q. Do you think it was lost to the west?

A. The closest well that is indicated where it could drain to would be to the south about three miles.

Q. Aren't you in the same pressure band when you go south? You don't get in the lower pressure band, do you?

A. Well, one of the wells is in this same pressure band—the same isobar, and the other one is on down a little lower.

Q. Which one is a little lower?

A. The one to the northeast. I would have to check those wells to tell exactly where they are.

Q. The one to the northeast could not drain to the south but a little lower?

A. The one to the northeast indicates that it drains locally to the north.

Q. As a matter of fact, if you will follow that out to the nearest well in the low pressure band, you go several miles from that point, don't you?

A. I want to find this description here.

Q. All right.

A. You failed to point out the high pressure wells.

Q. Wait until I get to it. Don't expect me to take all of this at once.

A. Over here is the Joseph Johnson—

Q. Wait a minute. You are getting into the high pressure wells and I am not wanting to get into that.

Mr. March: He is answering the other question.

The Trial Examiner: Why not let Mr. Keffer cross examine the witness in his own way, Mr. March?

Mr. March: I am, but he is coming in here and asking a general question as to where that gas drains to.

Mr. Keffer: When I asked him about drainage of a particular well I wanted him to confine his answer to a particular well.

* * * * *

Witness Hammer further testified on cross examination (Vol. 56, pp. 7785-7787,) as follows:

Q. Now, Mr. Hammer, just checking up a little on some of the matters that were covered generally yesterday, I believe I asked you if it was not very common in the oil industry to estimate reserves of oil-bearing sands based upon the potentials of the wells. When I say "potentials," I mean the producing ability of the wells; and as I use that term with respect to an oil well it is synonymous to open flow of a gas well.

A. No, I didn't—

Q. You don't know?

A. No.

Q. How long have you been in the oil business?

A. I started in 1912.

Q. All right, let me ask you this: Isn't it a fact that you have known many cases where oil production has been purchased—what I mean by that is that producing leases have been purchased—by persons experienced in the industry on the basis of so many dollars per barrel of potential?

A. Well, I wouldn't say yes. It has probably been done but that doesn't prove anything.

Q. Answer my question. Don't you know of many instances where it has been done?

A. On the potential of the well?

Q. So many barrels potential.

A. I think it has been done.

Q. Don't you know it has been done?

A. I never bought and sold—

Q. I know you haven't. I asked you if you didn't know of many many sales of that character.

A. I know of some.

Q. That has been spread over the entire period of the well?

A. Yes.

Q. The purchase of those properties were generally by pretty experienced oil men?

A. Yes, sometimes they were and sometimes they weren't.

Q. But they were generally?

A. Well, usually, yes.

Q. That is right. All right. Now, regardless of whether that was used to estimate reserves or not, it was used as a measure of value, wasn't it, of the potential of the well?

A. It was used as to what they thought the value was at that moment.

Q. And experiences have apparently justified that assumption, haven't they?

A. No, I don't think so, not in all cases.

Q. It has been done ever since 1912, hasn't it?

A. Yes, but I know of cases where wells have been bought on potentials that never even paid out.

Q. But still the practice is pursued, isn't it?

A. Yes.

The witness stated that he was also generally familiar with published reports on the Texas Panhandle Field which utilized the porosity sand thickness method for the determination of gas reserves, which reports were published in the American Association of Petroleum Geologists. He stated there is no absolutely perfect method for determining gas reserves. It is simply a question of the degree of perfection, and there is no method that he knows of that will give the correct answer. The witness believes that the pressure decline method has a decided advan-

tage over the porosity sand thickness method in the Texas Panhandle Field today. There was a time when the pressure decline method did not have an advantage over the other method, but he could not tell exactly when this was.

Witness began his study for the purpose of making the reserve estimate in 1935 and stated that if he had been making the estimate in 1935 and did not have dependable data prior to that date, he would still probably have attempted to use the pressure decline method, but with the understanding that his results would not have been very accurate, and from his viewpoint neither the pressure decline method nor the porosity sand thickness method would have been very accurate prior to 1935, and that prior to that time any estimate on the reserves of the Texas Panhandle Field would have been pretty much of a guess.

The witness stated that his method of determining the reserves for each quadrant wouldn't show the most prolific areas within that quadrant as compared with the less prolific areas, but would show some variation as between quadrants. For example, Moore County, Quadrant 2 was given an acre pound drop of 36.82 where Carson County, Quadrant 4 was given an acre pound drop of 81.43, which would indicate that Carson County Quadrant 4 was more than twice as productive as Moore County, Quadrant 2.

The witness Hammer further testified (Vol. 56, pp. 7802-7943) as follows:

Q. Mr. Hammer, you probably think you have already explained how you balanced your quadrants. You make a statement in your written statement that you did balance the quadrants—

A. Well, "balance" might not be the right term.—

Mr. Spencer: Let Mr. Keffer finish the question.

The Witness: —as it is really a grouping of the quadrants.

By Mr. Keffer:

Q. I would like to have you go somewhat into detail as to the manner in which you accomplished that.

A. Well, let me finish my answer.

Q. I beg your pardon.

A. Taking, for example, the one quadrant 3 used for illustrative purposes, that will explain it. The map shows that if you take Quadrant 3, Potter County, there is indicated by the isobaric lines a local movement of gas from Quadrant 3 in Moore County and Quadrant 2 in Moore County into the area in Quadrant 3, Potter County.

Now, you could not just utilize that area and make your calculation, so what we did—this is also indicated in the southeastern part of Hartley County into Quadrant 1—Quadrant 3, Potter County, a movement of gas down into Quadrant 3, Potter County, from Hartley County. There is also an indicated movement based upon the isobaric lines from Potter Quadrant 3 into Potter Quadrant 2; also there is an indicated movement of gas from both Quadrant 2 and Quadrant 3 in Potter County to Quadrant 2 in Moore County.

Now, obviously, to get a fair picture of what you would expect in this quadrant—

Mr. Lange: You mean Quadrant 3?

The Witness: Quadrant 3, Potter County, yes.

—you had to utilize Quadrant 2, Potter County; Quadrant 2, Moore County, and Quadrant 3 in Moore County, but that part of the field in Hartley County and Quadrant 3 in Potter County, by grouping those I arrived at a figure for the entire area; that is, the production per acre pound.

Mr. Lange: Which entire area?

The Witness: The entire area of the quadrants just named.

Then having arrived at that production per acre pound decline, I then took the weighted pressure, the difference between the weighted pressure of '39 and what I called the functional pressure, or the difference between the weighted pressure and the well head pressure of 25 pounds abandonment, and applied that weighted pressure—that weighted production per acre pound against the weighted pressure for this area.

By Mr. Keffer:

Q. That being true, why wouldn't you get the same per acre pound drop in each of the five quadrants we have been discussing?

A. You mean as finally arrived at?

Q. Yes.

A. I can explain that very easily.

Q. All right.

A. When we moved—take Moore County, Quadrant 2—

Q. All right.

A. When we moved over to Moore Quadrant 2 I eliminated this Hartley County and I simply took those quadrants adjacent to Moore Quadrant 2—

Mr. Lange: Which one?

The Witness: That would be Moore 3; Potter 2 and 3; Moore Quadrant 1; Quadrant 1, Potter, and Moore Quadrants 4, 5 and 6, and utilized those quadrants to get a factor for Quadrant 2.

Mr. Lange: Moore County?

The Witness: Quadrant 2 in Moore County.

Then I stepped over to the next one and I eliminated all of this over here (indicating).

Mr. March: What do you mean by "this"?

The Witness: All of these quadrants over here (indicating).

Mr. March: You mean to the west?

The Witness: And to the west.

And took in those adjacent to this quadrant.

Mr. March: Which quadrant?

The Witness: Quadrant 1, Moore County.

I utilized those surrounding it to arrive at this in Quadrant 1 and so on. In other words, that system was progressing clear across and eliminating continuously those at the west that had no particular bearing and couldn't have any particular bearing on the quadrant in question.

By Mr. Keffer:

Q. Now to get down to specific cases, when you figured Hartley County, Quadrant 3 in Moore, Quadrant 2 in Moore, Quadrant 2 in Potter, and Quadrant 3 in Potter, in order to find the acre content decline in pounds—in Potter Quadrant 3—what composite figure did you get before you made any adjustment?

A. That composite figure is a composite figure that is shown here on Table 3—

Mr. March: Exhibit 180?

The Witness: Exhibit 180.

By Mr. Keffer:

Q. You got 36.82?

A. That is right.

Q. I was looking for a cross on the exhibit here.

A. Which one are you talking about?

Q. I am talking about these five; that is, Hartley, Moore County 3; Potter County 2 and Potter County 3. I guess that is this figure here?

A. No, this is Hartley County. The next one is Potter 1.

Q. Well, now, let's get back to this. We are talking about this Hartley County area, particularly Quadrant 3 in Potter County.

A. All right, that is 35.1—

Q. That is right.

A. —per acre pound.

Q. 35.1., All right. When you figured these five quadrants we are talking about you didn't get 35.1, did you?

A. Absolutely. That is what this figure is here.

Mr. March: Where is that—in Exhibit 180?

The Witness: That is right.

By Mr. Keffer:

Q. That is the table for Quadrant 3?

A. It is the table from the calculation of the areas adjacent to Quadrant 3 applied to Quadrant 3.

Q. Let me see if I get that straight.

In determining the acre pound drop in Quadrant 3 you figured in the Hartley County quadrant, Moore Coun-

ty Quadrant 3, Moore County Quadrant 2, Potter County Quadrant 2, Potter County Quadrant 3, and you got a composite figure for acre pound drop in pressure which was 35.1?

A. That is right.

Q. You got that as applicable to the whole area and applied that to Quadrant 3, is that right?

A. That is right.

Q. I understand now. I thought you had another step in there in which you made some further adjustments with respect to Quadrant 3—

A. No, that is the entire procedure.

Q. When you did that you didn't figure in any other surrounding quadrants other than those just named?

A. Other than those adjacent to the quadrant for which we wanted to make our determination.

Q. Now, as a matter of fact, Mr. Hammer, when you did that you gave some weight in Quadrant 3 to producing areas in other quadrants, didn't you?

A. Yes, you take those all into consideration.

Q. And let us assume that Quadrant 3, for the purpose of this statement, is a very lean quadrant with a small amount of gas per acre; let us assume also that some of these other quadrants are very much richer per acre with a lot of gas in place, then haven't you unduly intensified Quadrant 3 with respect—

A. Let's make one more assumption you left out.

Q. All right, your answer would be no?

Mr. March: Just a minute. He is answering now. He hasn't said no yet.

The Witness: I will say no.

Mr. Keffer: You will say no and then go ahead and make your explanation?

The Witness: Here is an area—

Mr. Keffer: "Here," what do you mean by that?

The Witness: Wait a minute. You fellows don't give me a chance to answer a question.

Mr. Keffer: Mr. March was in on this, too.

Mr. March: You will have to describe the areas better.

The Witness: I will.

Here is an area in Quadrant 4 in Moore County, and here is another, Quadrant 3 in Moore County, extending over into Quadrant 3; Hartley County. I think this will clear up something that was confusing you yesterday. At any time you include an area where there has not been any actual or indicated decline in pressure in a calculation where it goes back, we will say, to the original pressure, and you have no indicated pressure decline as shown by your isobars, if you include that as against the production coming out of the areas around it, you then have a very minimum estimate of reserves in that area.

Taking the minimum there it would more than off-balance any other area that would enter into this calculation—

Mr. March: You said, "there"—

By Mr. Keffer:

Q. That is a matter of judgment?
A. It is somewhat a matter of judgment.
Q. Isn't it entirely so?
A. No, it isn't entirely so.

Mr. Keffer: All right. Go ahead, Mr. March.

Mr. March: I don't think you identified that last statement.

The Witness: It is Quadrant 3, Moore County.

By Mr. Keffer:

Q. What quadrants did you use on Hartley County in figuring the reserves there, Mr. Hammer?
A. (Pause).
Q. It doesn't have a number? It is called HA Quadrant, isn't it?
A. There is only one there.
Q. Yes, that is true.
A. I used Hartley, Potter 3—I notice there is a mistype here. That should be "Moore 3" instead of "Moore 2".

Mr. Lange: What table is that?

The Witness: That is on Table 3.

Mr. Lange: Exhibit 180?

The Witness: Yes, sir, that is right.

Mr. Lange: We might be able to make that correction at this time.

The Witness: The correction is that instead of being Moore 2 as it is typed here it should be Moore 3.

Mr. Lange: Where should the correction be made on Table 3?

The Witness: In Column A, right after "M-2." That should be "M-3."

Mr. Lange: Under "Hartley"?

The Witness: Under "Hartley."

Mr. Lange: The second line under Hartley that says M-2, should be M-3?

The Witness: That is right.

Mr. Lange: Mr. Examiner, can that correction be made in the exhibit?

The Trial Examiner: That correction will be made.

Mr. Hammer, I gather that these capital letters appearing under Hartley and Potter 1, 2 and 3 and Moore 1, represent the county?

The Witness: That is right.

The Trial Examiner: The county for each particular quadrant?

The Witness: That is right.

Mr. Lange: That correction can be made, then?

The Trial Examiner: Yes, sir. We will have the reporter make that correction.

By Mr. Keffer:

Q. You stated, I believe, after the correction was made, considering the Hartley County area, that you considered Potter County 3, Moore County 3, and Moore County 4; is that right?

A. And Hartley.

Q. And Hartley?

A. That is right.

Q. What was the occasion of using all of those on your Hartley County quadrant, Mr. Hammer?

A. Well, it occasionally was, as I mentioned a while ago, that there the isobars indicate a drainage from Hartley County down into Potter County, Quadrant 3. The similarity of the characteristics as nearly as we could tell them, as far as pressures were concerned and the drainage away from the area in Quadrant 3, Moore, and also in Hartley County, for that reason we used the adjacent Quadrants to determine what we considered a fair production per acre pound for Hartley County.

Q. All right, that doesn't apply to Quadrant 4 in Moore County, does it?

A. Well, there is a new development down there that comes up against the corner of Quadrant 4, and in Hartley County in the northeast part of that productive area. There is some new development there and any gas that will move from there does have a bearing on the southwest or would have some bearing on the southwest part of Quadrant 4, Moore County.

Q. Has there been any production from that well?

A. I would have to check on that as I don't remember.

Q. Isn't it your offhand recollection there hasn't been?

A. I would say that that is possibly true, although I wouldn't want to state.

Q. Is that the Phillips Petroleum Company's well that was drilled in there a year or two ago?

A. I would have to check it as I don't remember it.

Q. Let's come back to the map.

A. Yes.

Q. So far as your isobaric lines are concerned, it doesn't indicate any drainage from Hartley County quadrant into Quadrant 3, Moore County, does it?

A. Well, it is difficult to say.

Q. You take the thing we agreed upon. Your drainage patterns are at right angle to the isobar lines?

A. Yes, as a general rule.

Q. And your isobaric lines in there run generally east and west so you get about the same pressure on the west side of Quadrant 3 as you do on the east side of Hartley County quadrant, isn't that correct?

A. That is in general true.

Q. That is exactly what your map shows?

A. Yes.

Q. And if that is not right, your map is wrong, is that the point?

A. Yes.

Q. Come down to the Potter County quadrant. How much drainage do you show out of Hartley County into Potter County? How does it get in Potter County?

A. It comes down, hits a barrier where it can't go on, and it moves in this direction.

Mr. March: Which direction?

The Witness: Southeast along the fault line. You have a lower pressure area down here than you have up there (indicating).

Mr. March: What do you mean?

The Witness: In the north extreme western part of Potter County, Quadrant 3.

By Mr. Keffer:

Q. Of course, it shows your isobaric lines the same, 390 in Potter County and 390 in Hartley County?

A. Yes, and that would mean that gas would migrate.

Q. From 390 to 380?

A. From 420 to 410 and 390. It means there is migration there. It is moving down into this point of Quadrant 3 (indicating).

Q. What part would this well right on the fault line play in that?

Mr. March: Describe it.

Mr. Keffer: It is a well in Hartley County, Block 2, —I can't read the section number—being the only well in Hartley County within an eighth of a mile of the fault line, that is, that is designated on the map.

Q. What effect would that well have?

A. It would have some effect, unquestionably.

Q. But you think some gas would still migrate into Potter County?

A. I think so.

Q. Take up in Quadrant 4, where do you get your drainage—Moore County?

A. I will agree the map in this particular instance shows no drainage from that into quadrant—I mean into Hartley County, or vice versa.

Q. Or vice versa?

A. Yes, but let me point this out: As I explained a while ago, by utilizing an area of original field pressure at 430 pounds, if I included that area I have then had an actual minimum of gas to apply to the Hartley County area.

Q. What do you mean, that you would have a minimum?

A. Well, you can't draw isobars out into territories clear away from where there are producing wells and then include those outside areas. If you include them you are bound to get a minimum production per acre pound, depending upon the size of the area.

Q. Wouldn't it be just the opposite? Wouldn't you get a maximum where you were taking in a quadrant virtually virgin in pressure throughout?

A. No, you are getting back to that remaining reserve per acre.

Q. Yes, possibly so, but tell me why you wouldn't get that.

A. I have already explained it.

Q. Let's try it once more and I can possibly get it.

A. As I explained a while ago, this question of remaining reserves per acre hasn't anything to do with the calculation of the reserve question at all.

Q. Let me approach it in another way: To do so I will assume this: If as a matter of fact Quadrant 3 in Moore County is more productive per acre than Hartley County quadrant then you have increased your production per acre in Hartley County by figuring Quadrant 3, Moore County, into it?

A. Let's see. You say that if Quadrant 3, Moore County, is more productive—

Q. Per acre, than Hartley County quadrant, then when you average Hartley County quadrant in with Quadrant 3, Moore County, you have necessarily increased the calculated acre content in the Hartley County quadrant?

A. No, you are still confusing those remaining reserves.

Mr. Keffer: Let's don't talk about it.

The Witness: That is what we are talking about. I don't propose to have remaining gas reserves confused at all.

Mr. Keffer: We are not confusing them.

The Witness: No, we are not.

Mr. Keffer: That is entirely out of my mind. I don't want you to figure on remaining gas reserves. I want you to figure on original gas reserves. There isn't any need for there to be any confusion unless you deliberately talk about one thing while I am talking about another.

The Witness. I want to get it straight. This remaining reserve per acre in Mcf. is an after thought and it was simply illustrative.

Mr. Keffer: Just forget about it.

The Witness: All right.

Mr. Lange: In order to identify it, you are referring to the remaining reserves per acre as set forth in Exhibit 186?

The Witness: It is also set forth in Exhibit 180.

Mr. Lange: Both of them?

The Witness: Yes.

Mr. Keffer: That is all I am trying to do, just trying to illustrate as you were in the other instance.

The Witness: Suppose we wait until we get the original reserves for the various quadrants before we go into that.

Mr. Keffer: If that is satisfactory to the Examiner it would be satisfactory with me, but I don't like to leave this subject now and come back to it later.

The Trial Examiner: Perhaps we might take a short recess at this time.

Mr Keffer: I would prefer to do that rather than go into something wholly unrelated and then come back to this at a later time.

The Trial Examiner: We will stand in recess for five minutes.

(At this point a short recess was taken, after which proceedings were resumed as follows:)

The Trial Examiner: The hearing will be in order.

Mr. Keffer: Mr. Examiner, I can proceed for a little while with Mr. Hammer, even though we don't have the information that was requested. However, I can only go to a certain point. It may take until the noon hour to reach that point, I don't know, but I would like to have it understood that if I do get some of these other matters out of the way rather expeditiously, and it isn't quite the noon hour, that I would like to wait until the additional information is available before proceeding further.

The Trial Examiner: Very well, Mr. Keffer. You can go as far as you can and we will recess through the lunch hour. Perhaps the papers that could not be found by Mr. Hammer can be located by him during the lunch hour.

Mr. Spencer: Mr. Lange advises me that he has some other things he could fill in with to facilitate our running until the lunch hour.

The Trial Examiner: Very well.

By Mr. Keffer:

Q. Mr. Hammer, we were discussing primarily the Hartley County quadrant at the time we recessed. Now, I will still have some other more or less general questions regarding your method of computing reserves which I can develop at this time. I will try not to get too much into the question of remaining reserves or original reserves or acre per pound drop until we get that additional information. It may come in at times but I will stay away from it as far as I can until we do get that information. Is that satisfactory?

A. Very well.

Q. Mr. Hammer, when you figured Quadrant 2, Moore County, just what quadrant did you take into account then?

Mr. Lange: Which table in Exhibit 180 are you referring to, Mr. Keffer?

Mr. Keffer: I am referring to the table on the back of Page 5—.

Mr. Lange: Table 3, Page 5?

Mr. Keffer: That is right. I am referring to Moore County No. 3 quadrant.

The Witness: You are referring to Moore County, Quadrant 3?

Mr. Keffer: That is right.

The Witness: Hartley County, Potter 2, Moore 2, Potter 3, Moore 3, Moore 4 and Moore 5.

By Mr. Keffer:

Q. Now, in figuring Quadrant 3, Moore County, you have taken in just one additional quadrant, haven't you, and that is Quadrant 2 in Moore County?

A. One additional—

Q. That is, one additional quadrant in addition to those you did consider while you were figuring the Hartley County quadrant?

A. No, that isn't true. In Hartley County I used Hartley, Potter 3, Moore 3 and Moore 4.

Q. All right.

A. That is 1, 2, 3, 4, 5, in Moore 3—

Q. It is just 4, isn't it?

A. 4, that is right. In Moore 3 I used Hartley, Potter 2, Potter 3, Moore 2, Moore 3, Moore 4 and Moore 5.

Q. Yes, and you added Moore 2 and Moore 5?

A. That is right.

Q. I didn't think you had used Moore 5 but I hadn't checked.

I will ask you again, looking at your isobaric lines and assuming that your gas flows at right angles to your lines, how did you figure that any gas out of Quadrant 3, Moore County, got into Quadrant 5 or vice versa?

A. I didn't figure it, but it did get into Quadrant 3.

Q. How is that?

A. I didn't figure there was any out of Quadrant 3 that got into Quadrant 5.

Q. Or vice versa?

A. Not from Quadrant 3, but from Quadrant 4.

Q. Quadrant 4?

A. In that case the isobars indicate the pressure differential between 4 and 5.

Q. What does that mean?

A. It means probable local migration into Quadrant 5.

Q. But we are not figuring Quadrant 5, we are figuring Quadrant 3.

A. All right. What we are doing is balancing it up. Let's get this straight. If I take a quadrant, any one of them where I utilize them in this group and assume that there is more production and more reserve, if I utilize one with a less reserve and I take the total acreage, why, it makes the lesser one greater and the greater one lesser, so you get a balance.

Q. Let's go just a step further. Doesn't your map indicate some drainage out of Quadrant 5, Moore County, into Quadrant 6, Moore County?

A. Very very slight, if any.

Q. All right, doesn't it indicate some drainage out of Quadrant 2, Moore County, into Quadrant 1, Moore County?

A. No.

Q. None at all?

A. No.

Q. Well, what is this isobar here—your 360?

A. That is 380.

Q. 380?

A. Yes.

Q. What is the next lower one, or is that a lower one?

A. That is your 360.

Q. 360?

A. Yes.

Q. Wouldn't gas flow from 380 to 360?

A. All right, here is a 380 again—

Mr. March: Where is that?

The Witness: Quadrant 1. It is in the western part of Quadrant 1.

By Mr. Keffer:

Q. Take the big area south of that high you might have there, what do you have then?

A. There is nothing there to indicate any drainage from 2 to 1.

Q. We have in your first isobaric line near the east central part—your isobaric line is in the east central part of Quadrant 2, 380 pounds contour line, directly east of that, and in Quadrant 1 we have a 360-pound line—

A. Yes and here we have 380 pounds.

Mr. March: Where is that?

The Witness: In the western part of Quadrant 1 you have an equal pressure here (indicating). You don't have a decline here (indicating). If there were any particular drainage at that point it would be north but the distance here (indicating) is so great—the pressure is an equal pressure—but you don't have over five pounds differential; until you get over here it doesn't amount to anything. Here you would have ten pounds but it is all close together, but over in Quadrant 1, Moore County—

By Mr. Keffer:

Q. You have 20 instead of 10?

A. No, these are ten isobars (indicating).

Q. I thought you said 360.

A. This is 360 and this is 380 (indicating).

Q. You outline the higher pressure which we have been referring to north of the drainage area we have been speaking—a little north of the drainage you have been speaking of as having no influence on it at all?

A. What pressure are you referring to?

Q. The one you have been referring to.

A. Certainly it has a distinct bearing. Gas won't flow against a pressure that is higher.

Q. I am talking about the flow from 380 to 370, Mr. Hammer What is that pressure up there?

A. This is a 370 instead of a 380. It is this isobar that cuts the end of the northeast corner of Quadrant 2, goes into Quadrant 1, Moore County, and extends in a general southeasterly direction across the quadrant. That is a 70 and not an 80.

Q. What is that—an 80? Where do you get your 80 on there?

A. Well, it is from the pressure on that well there.

There is a well here in Section 46, T & N O Survey, Block 16; that has a pressure of—as I read it on this map here it is 380. You would then have a 380 isobar between those two wells.

Q. You show that as a very localized condition, don't you?

A. Well, it covers quite a little area.

Q. It covers a little more than a Section, say a thousand acres at the outside?

A. All right.

Q. That is a very little estimate, isn't it?

A. You made the estimate.

Q. I am talking about an area about a mile or two south of that, south of even where you have your lines drawn. Let's stay with that area down there.

A. All right. You were talking about the distance east, weren't you?

Q. No.

A. You mean the distance over here from—

Q. I am mentioning the differences between pressures—

A. All right, I know you are.

Q. Go ahead.

A. But here you have 1, 2, 3, 4 miles, and in that four miles you only have a difference of pressure in the amount of ten pounds. If through four miles of the character of material of which that is composed—

Q. What is the character of the material?

A. I don't think anybody knows, but we do know they—

Q. All right, go ahead.

A. We know the permeability varies to beat the band. Over an area of four miles with a ten-pound differential you wouldn't have very much drainage, if any.

Q. How do you know you wouldn't?

A. It is just common sense.

Q. You don't even know the kind of material it is going through, yet you say there wouldn't be any drainage?

A. We do know the whole formation has variable characteristics both as to permeability and as to porosity.

Q. Certainly. There isn't any question about that, but you don't know the kind of formation you have there or any other place in the field, do you?

A. I do know if you only have a 10-pound differential in four miles you are not apt to have very much drainage.

Q. Let's take a pipe line with ten pounds differential. Would gas go through that line?

A. There isn't any comparison—

Q. Answer my question.

A. A pipe line is an open tube without any restrictions in it, and here you have an infinite number of pores.

Q. How do you know you have?

A. It is characteristic of all formations.

Q. Well, some are more permeable than others, aren't they?

A. What?

Q. Some are more permeable than others, aren't they?

A. Well, yes, naturally.

Q. You paid no attention to the permeability?

A. The fact remains you can't make a comparison as between any underground formations in a pipe line.

Q. Again you have stated here, and you stated yesterday a number of times you knew nothing about the formations and made no particular study of porosity or permeability?

Mr. March: He never stated that.

The Witness: I never said that.

Mr. Keffer: Let the witness answer the question.

The Witness: I said I made no study of porosity or permeability.

Mr. Keffer: We will limit it to porosity or permeability.

The Witness: That is right.

By Mr. Keffer:

Q. Then you don't know what the porosity is across the four miles and what the permeability is across the four miles?

A. It really doesn't make any difference. Any geologist who knows anything at all about production horizons knows that in four miles with only a 10-pound differential in pressure between the two points that you are not apt to have any appreciable movement.

Q. You are now hedging on me a little. Go ahead.

A. That is all.

Q. Oh, that is all? You could have a highly porous and highly permeable situation there and you would have a substantial movement of gas with a 10-pound differential, wouldn't you?

A. No, not necessarily.

Q. That is your answer?

A. Yes, that is my answer.

Q. We will let it stand.

Now, Mr. Hammer, getting back to where we were before recess—during recess I got off of the thing I hadn't completed on the Hartley County area—I believe you admitted that while we were on that, as far as your map disclosed, there wasn't any drainage from Hartley County into Moore County Quadrant 4, or vice versa?

A. I think that is true.

Q. Yet you did use Moore County Quadrant 4 in figuring out Hartley County?

A. Yes, and by using it I gave a lesser reserve to Hartley County Quadrant 1 than if I hadn't used it.

Q. You have some pressure drops in Hartley County, didn't you?

A. Yes, some.

Q. You had over 80 per cent or more of Moore County Quadrant 4 where you didn't show any appreciable drop?

A. That is right.

Q. When you averaged those high pressure areas of Quadrant 4 in Moore County with your lower pressure area in your Hartley County quadrant, now as a matter of fact, didn't that give you a higher pressure over the two quadrants than you had originally in Hartley County?

A. No, not—it gave you a higher pressure but it didn't give you a higher production per acre pound; it gave you a smaller one.

Q. It gave you a smaller production per acre pound, that may be true, if you take the same volume of gas and increase your acreage. That would be inevitable, wouldn't it?

A. Yes. The point I am trying to make is that it gives you a minimum reserve.

Q. What does it do to Quadrant 4?

A. Well, it also gives that—when you calculate that thing out it gives it a minimum reserve.

Q. What does it do to all the rest of them?

A. The point I made a minute ago—

Q. Answer my question, please.

A. I am going to answer it.

Q. All right.

A. If you take an area of larger size and take the gas from it alone and apply the gas removed from it to a larger area—larger acreage, and particularly to an acreage where you have no indicated decline at all, then you are going to very materially decrease the production per acre pound decline.

Q. Now, if those additional acres that you would add were not very productive acres, and you added it in with this acreage down here in Quadrant 4 and then you averaged them out, don't you get a distorted figure in both quadrants?

A. No, not particularly, because I am averaging the principal—

Q. You are just averaging, is that all you are doing?

A. No, grouping.

Q. What is the difference between grouping as you do it here and averaging?

A. Call it averaging if you want to. I won't argue with you.

Q. Isn't that what it is? If it isn't averaging, I don't want you to say it.

A. It is a utilization of a quadrant and those immediately adjacent to it to determine the average production per acre pound for the area and then applying it to the area in question.

Q. All right. Now, when you took that Hartley County quadrant and you averaged all of those other quadrants in here that you talked about, you had a calculated per acre pound decline of 34.43 pounds, didn't you?

A. That is right.

Q. In all of the quadrants that you figured?

A. Yes, for the group.

Q. And you added to that one in Hartley quadrant and you had the same figure in Moore County 3, didn't you?

A. For the entire group used.

Q. And Potter County 3 and Moore County 4?

A. All right.

Q. You had that 34.43 pounds?

A. That is right.

Q. Then when you came down to figure Potter County 3, what did you get when you figured that one again?

A. 35.1.

Q. This time you got 35.1 in Quadrant 3, the other time 34.3—

A. Wait a minute. The 34.43 was the grouping for the entire area.

Q. And that is a part of the area?

A. Yes, but I did not when I arrived at the production per acre pound for Quadrant 3, Potter County, use the quadrants I used in the determination of it for Hartley County.

Q. And you got a different value for Quadrant 3?

A. Yes, because I eliminated the one adjacent to it.

Q. Certainly, there is no question about it.

Now, when you figured Quadrant 3 in Potter County, you took Quadrant 2 in Potter County into account?

A. That is right.

Q. And for the area, which included Quadrant 2, you got 35.1 pounds, didn't you?

A. Quadrant 2, Potter County?

Q. Yes.

A. When I calculated the area for Potter Quadrant 2?

Q. No, when you were figuring on Quadrant 3 you got 35.1 pounds in Potter County 2 because it was part of the area you figured—

A. Taking in the whole area?

Q. That is right.

A. That is right.

Q. You got 35.1. Well, what did you get in Quadrant 2 when you figured it?

A. Well, the whole point is that I did not—

Q. Answer my question, please.

A. I am answering your question.

Q. No, you're not.

A. I am, too.

Q. Just give me the pounds you got.

The Trial Examiner: Give him the pounds, Mr. Hammer.

The Witness: All right.

Mr. March: He can make any explanation he wants to.

Mr. Keffer: That's all right, let him answer my question.

The Witness: You wanted to know in Potter 2?

By Mr. Keffer:

Q. That's right.

A. All right. 42.71.

Q. The other time you figured it you got 35.1, when you figured it the other time?

A. No, you can't compare the two, because I used different acreage.

Q. Let me ask you another question: When you were determining the per pound drop in Quadrant 3 you determined Quadrant 2?

A. That's right.

Q. And over the whole area including Quadrant 2, you got 35.1 pounds?

A. That's right.

Q. Then when you came over to Quadrant 2 and took in a little different area, then you got on Quadrant 2, 42. plus pounds?

A. That's right.

Q. When you figured Quadrant 2 you took in Quadrant 1 in Potter County, didn't you?

A. That's right.

Q. You necessarily got 42 plus something in Quadrant 1 in the whole area, didn't you?

A. Not in Quadrant 1 in the whole area.

Q. All right, when you came down and figured Quadrant 1 together with other acreage, what did you get?

A. Quadrant 1 which?

Q. Potter County.

A. 58.97.

Q. 58.97. All right, you get a different answer every time you make a different calculation in each quadrant, don't you?

A. That is because—it is easily explained. We are making a progressive determination eliminating areas that aren't adjacent to the areas. When you take in new areas with different characteristics you are bound to take—you are bound to get new answers.

Q. And you do get new answers for every Quadrant every time you make an additional calculation?

A. No, that isn't true at all.

Q. Let's run through.

A. All right.

Q. All right. Take Quadrant 2 in Moore County. When you figured it in with Quadrant 3, you got—Moore County—you got on it 34.58 pounds, didn't you?

A. You are talking about what—Moore 3?

Q. I am talking about Moore 2.

A. Moore 2.

Q. When you figured it in with Moore 3 you got a weighted average of 34.58 pounds per acre pound drop?

A. Well, you are talking about Moore 3.

Q. No, I'm talking about Moore 2. When you figured it in with Moore 3.

A. You have got the wrong figure. It is in the column above. Moore 2 is above 3.

Q. Oh, we'll go through the whole thing again. When you were determining the remaining reserves as you have it here on this map of Quadrant 3 in Moore County, you included among other quadrants, Quadrant 2 in Moore County, didn't you?

A. That's right.

Q. All right, now, you figured, then, the acre pound drop for the area which included Quadrant 2, Moore County, 30.58 pounds, didn't you?

A. In arriving at a production per acre pound for Quadrant 3.

Q. That's right. You included Quadrant 2 and got 30.58 for the whole area?

A. That's right.

Q. Then when you came down to figure Quadrant 2, you had a little different area. What did you get then for Quadrant 2, Moore County?

A. Under the group determination I got 36.82.

Q. 36.82. You got still a *differn* figure.

A. Sure.

Q. All right, now, let's come back to Hartley County. When you figured it out the first time you got 34.43, didn't you?

A. Using the group.

Q. By using the group, that's right. When you made a separate calculation on Quadrant 3, Moore County, it included Hartley County, didn't it?

A. Yes.

Q. That time you got 36.58, didn't you?

A. For the entire group, yes.

Q. For the entire group which included Hartley County?

A. That's right.

Q. So now you have got two figures depending on which way you figure it in Hartley County, haven't we?

A. No, we haven't.

Q. Well, we had 34.43 one time and I believe 30.58 another time, different figures.

A. You are confusing the group production per acre pound as determined as against the production per acre pound utilized in determining the reserves of a particular part of that group.

Q. Here is what I am doing, and see if this is not a fair statement, Mr. Hammer:

I go out with you and I tell you that I want to buy all of the acreage in Quadrant 3, Moore County, Texas, and I want you to tell me the value of it. You go ahead and figure that value out and you get it predicated upon 35.58 pounds, per acre drop in pressure and you figure back your reserves from that.

Mr. March: Now, just a minute, Mr. Keffer.

Mr. Keffer: Let him answer. Wait until he answers and then you can talk all you want to.

The Witness: That's right.

By Mr. Keffer:

Q. All right, then you get that 30.58 that we just referred to.

A. That's right.

Q. All right, I'll ask you, Mr. Hammer, how you got that—well, you say that the average of all those surrounding quadrants—well, I have got that. Then I decide I will buy Quadrant 2. Now, you gave me a figure which is 30.58 for all the quadrants, average, and I go out to buy Quadrant 2 on that and I will get into a mess, won't I?

A. No, you won't, not if you are employing me you won't.

Q. All right, now, go ahead.

A. I will eliminate Hartley entirely when I get over to Quadrant 2 and I will utilize the surrounding areas to find out what the proper figure for that is, and naturally I will get another figure because I am using different data.

Q. All right. Suppose I want to buy Hartley County, Moore 3, Potter 3, how do you do that?

A. Just as I did in this estimate.

Q. Would you just eliminate those outside lines of those quadrants?

A. I haven't done it in any case.

Q. Suppose I wanted to buy all those surrounding quadrants how would you figure that?

A. Buy all the surrounding quadrants?

Q. Yes, together—the whole works, I want to buy all of Moore and Hartley and Potter County.

A. Well, just by the method used I would give you the reserve.

Q. Slip over and take these adjoining ones in Hutchinson County and Carson County.

A. That's right.

Q. Supposing I wanted to buy those two, then how would you figure it?

A. Well, if you wanted to buy the whole field—

Q. I haven't got enough money quite yet to buy the whole field.

A. I would figure the same just as I have figured this thing. Naturally, as I have stated a while ago, we used a process of eliminating and we followed that thing clear through the field from end to end.

Q. Yes.

A. All right. That ought to explain it.

Q. Well, if you will answer my question, maybe that will explain it to me better. If I wanted to buy all of Moore and Potter Counties plus the adjacent quadrants in Carson and Hutchinson County, how would you figure it? You would take the eastern quadrants in Hutchinson and Moore County and figure them all in?

A. That's right.

Q. You go right down the line until you have covered the whole field?

A. Why, certainly, I have just said that.

Q. All right, then, you have got a fieldwide figure in effect, or figured the field in whole in effect when you considered Canadian River, didn't you?

A. No, I didn't have to at all. I will tell you why I didn't have to. I considered—

Mr. March: Where is that?

The Witness: Now, wait a minute. I considered Quadrant 3 in Carson County. Now, there is nothing there on that map or any map over a five-year period that indicates any possibility of any drainage eastward from Quadrant 4 over into Quadrant 2 in Carson County. Therefore, utilized Quadrant 3 and grouped it around Quadrant 4 in Carson County and there was no need of going any further east than that. That gave me all of the data I needed to calculate your reserves.

Q. All right, now, let me see, Mr. Hammer. You say you figured Carson 3, Quadrant 3, Carson County, in with Quadrant 4, Carson County?

A. That's right.

Q. And you got a weight for Quadrant 3 and Quadrant 4 and those others that you might have considered, didn't you?

A. Yes.

Q. As applying to all of them?

A. Or the group around that.

Q. All right, now, just take that just a step further. Quadrant 3 at the very time you were making that calculation had been losing gas by drainage to Quadrant 2, Carson County, hadn't it?

A. Well, yes, probably, but very little.

Q. Well, but it had been losing some by drainage?

A. So small a part in relation to the whole, it would be insignificant.

Q. How do you know it is small?

A. Well, take the area—come over here in the eastern part of 3 and the configuration of isobars there show that your drainage will go straight north. Now, when you get over to the east in the last two sections you might have some slight drainage, but it is so small it is insignificant.

Q. How about this part (indicating)?

A. That is not—it doesn't affect it at all.
Q. Why doesn't it?
A. Well, look at the isobar.
Q. What is that number?
A. Well, that is—
Q. No. 370.
A. 370.
Q. That is the next one northeast.
A. 360.
Q. All right, why isn't there drainage from 370 to 360?
A. I didn't say there was none. I said very very small, if any.
Q. You said there was none at all in the south part, that what little there was up in the east central part.
A. Well, that is a relative term, but I stated that there is nothing in that picture or any picture over a five-year period that indicates any appreciable drainage at all except possibly along the extreme eastern edge.
Q. What is the permeability and the formations there?
A. The same as any other.
Q. Then it is common over the field?
A. I don't know the permeability nor neither do you or anybody else, nor do I know the porosity.
Q. All right, now, when you figured Quadrant 3, what did you take into consideration in Carson County, Mr. Hammer?

The Trial Examiner: You mean what quadrants?

Mr. Keffer: Yes, what quadrants?

The Witness: Those immediately surrounding.

By Mr. Keffer:

Q. All right, then you did take into account quadrant 2, didn't you?
A. That's right.
Q. There was no drainage, you say. Then, why did you do that? Why was there necessity to do that?
A. Well, I said there was some slight drainage, yes.
Q. But you said a while ago there wasn't enough to make any difference when figuring back west, but when figuring east it makes a lot of difference, is that your point?
A. No.

Q. All right, state it.

A. My position is that in Quadrant 3, Carson County, over a five-year period there is nothing to indicate any drainage—I mean the configuration of the isobars are such that you would have no drainage from Carson 3 into Carson 2 except along the eastern portion, and it would be small.

Q. But you did figure that it was enough drainage in computing Quadrant 3, don't you think you ought to consider also Quadrant 2?

A. Yes, that's right.

Q. All right. Now just drive a peg there and hold it there a moment, but when you are figuring Quadrant 4 to the west you took in Quadrant 3 in getting your composite figure for all of the quadrants considered, but you gave no consideration to Quadrant 2, Carson County. Now, isn't that right?

A. I think that is right, and the reason for it is that as I have stated here three times in succession and I will state it a fourth—

Q. All right, I am asking you.

A. That any drainage of Quadrant 3 into Quadrant 2, Carson County, would be such a minimum amount, based upon an opinion of the five years of isobars, that it would be insignificant as far as anything affecting Quadrant 4 is concerned in Carson County.

Q. Now let's get Quadrant 2, Carson County, that has affected Quadrant 3 of Carson County, else you wouldn't have used it when you were computing Quadrant 3, would you?

A. It had some effect on Quadrant 3.

Q. All right, now, the effect, whatever it had—whether it was great or little—was not taken into account when you figured Quadrant 4 and weighted Quadrant 3 into it.

A. Well, there might be a slight—there would be possibly a slight amount there but it would be so small it would be insignificant.

Q. "Might be"—isn't it postive that it is? Is there any question about it?

A. I say, if it is, it is so small that it is insignificant.

Q. All right, you do admit there was an error in that respect?

A. Well, I recall it.

Q. That is where a matter of judgment came in?
A. That's right.
Q. The other day you said judgment didn't come into this.
A. I said I used the same judgment in minor instances. Let's go a little further on this thing, Mr. Keffer.
Q. All right.
A. I previously stated that we balanced these things out clear across, using adjacent quadrants. I presume that if I continued on to balance those things clear on out over here into Wheeler County that you would say that it had an effect on your reserve over here?
Q. Well, wouldn't it?
A. No, not at all. I might just as well explain that now as any other time.
Q. That's right.
A. The Texas Railroad Commission itself and I think most of the geologists that have done any work in the field recognize the fact that here in the vicinity of Lefors in Gray County they make a separation between the fields. They call—the Texas Railroad Commission always refers to that as the east sweet field, and they refer to this on this side as the west sweet and the west sour field, so when you get beyond that point in there some place, all of the rest of that from the vicinity of Lefors on east is the eastern field.

I take this position: The reason why that is done is that there is no chance at all in the opinion of the Texas Railroad Commission of any direct connection between the east field and the west field.

Q. What do you mean, "any direct connection"?
A. Well, as far as any gas movement is concerned.
Q. There is a direct connection?
A. Well, as far as any gas movement is concerned, that is the reason the Texas Railroad Commission did it.
Q. What do you mean by the opinion of the Texas Railroad Commission?
A. Well they established the line.
Q. Can you quote anything that they ever said in writing?
A. No.
Q. Did you ever see anything anywhere that they made the statement you just made?

A. I have taked with their engineers and other folks too. I don't know that they have published it, but the fact remains that they did it.

Q. Don't you know the facts why they cut that off and called that the east field and the west field?

A. Well, just as I stated.

Q. Do you know when it happened?

A. I know that in the opinion—in my opinion and in the opinion of lots of folks I have talked to, as far as any economical consideration is concerned there is no likelihood of any gas moving from that eastern part of the field that would affect anything in an economic sense in the western part of the field.

Q. All right, let me state it this way: Do you know that that east part of that field was cut off—I say, "cut off"—was considered separately from the standpoint of proration only and that was the only reason for it?

A. Well, I don't know that, no.

Q. You don't, and do you know that tracts, and do you know that tracts in the eastern counties usually are small, a lot of 160-acre tracts and 160-acre leases, that the tracts and leases are bigger in the west field and the Commission wanted to zone the field so as to establish a different spacing rule in Wheeler County in the east field than what they had in the west field? Don't you know that to be a fact?

A. I don't know what their opinion was. I do know that the acreage in Wheeler County is in smaller farms—in smaller areas.

Q. All right, do you—you do know that in every published report that you ever saw concerning the Panhandle field, included Wheeler County wells along with the rest of the field, didn't it?

A. Yes, but the Texas Railroad Commission's reports always referred to it as the east and west field.

Q. In giving the weighted pressures for the Panhandle field, does the Texas Railroad Commission take Wheeler County into account?

A. Yes, I believe it does.

Q. Therefore, the Railroad Commission considers it all one reservoir and considers the pressures in Wheeler County have something to do with the pressures in the rest of the field, is that not correct?

A. Well, you will have to get that from the Railroad Commission.

Q. All right, we'll go back. You got a lot of things from the Railroad Commission and I thought maybe you got that, too. They do in weighting out pressures for the field consider the whole field in giving the weighted pressure for the Panhandle field?

A. I believe that is true.

Q. All right, now, Mr. Hammer, you might have to draw on your imagination to say that a cubic foot of gas—a small particle of gas—that started moving out here in Hartley County would end up over here in Wheeler County? Now, that is the point you were trying to make a while ago.

A. The point I was trying to make?

Q. Yes. It would just get lost before it got to Wheeler County, or just get tired moving and stop before it got that far.

A. Well, it would probably meet one of these hypothetical barrier or actual barriers you set up yesterday, and couldn't go any further.

Q. I am going to agree with you. I am not a geologist, bear in mind. It would be unreasonable to expect a minute volume of gas like—say a drop of gas—that isn't a very good word, but we will say a cubic foot of gas—that started over here in the tip of the field over in Hartley County would finally be produced out of a well in Shamrock over in Wheeler County?

A. That would be true.

Q. That would be too much to expect?

A. That is true, and it would be equally true if you had an infinity of those little particles.

Q. All right, but when a movement starts over here, you get a low pressure area and it draws from the higher pressure area in the west of it, doesn't it?

A. No, only locally.

Q. All right, let's get our stock illustration. We can go better at Borger. You have a low pressure area at Borger, haven't you?

A. Yes.

Q. It takes from the next higher pressure to the southwest?

A. And to the northwest and southeast.

Q. But it does come from the southwest?

A. Yes, and from the others too.

Q. All right, when it takes from the southwest it reduces the pressure in that band, doesn't it?

A. Now, let's see if I get what you mean. I am not sure —you talk about bands—

Q. I am talking about a pressure band, the bands between your contour lines—isobar lines.

A. Repeat that question.

(The question referred to was read by the reporter, as set forth above.)

By Mr. Keffer:

Q. The next higher band.

A. Yes, that is the natural thing.

Q. All right, then, what happens to that next higher band? The pressure has become lower and it takes some gas from the next higher band, doesn't it?

A. That is where the pressure always comes from.

Q. All right, that band becomes lower and it takes some gas from the next higher band, doesn't it?

A. That is a natural assumption.

Q. That band becomes lower and it takes some gas from the next higher band, doesn't it?

A. Qualifiedly, yes.

Q. What is the qualification?

A. You reach the point after while where, as your isobars get farther and farther apart on any given map, it becomes less and less and less all the time.

Q. All right, we'll come to that in a moment. Those things do exist.

A. Oh, yes, they do exist.

Q. All right, by reason of the low pressure in Borger you would have a displacement of gas back in the Canadian River reserves without the necessity of gas actually starting its movement in the Canadian River reserves and actually ending up over at Borger, wouldn't you?

A. What is the point of Canadian River area—reserves your are talking about?

Q. Any part of it.

A. Oh, that is not true.

Q. All right, what's wrong with it?

A. Well, I think it is just about time to get some facts in here.

Q. I do, too. Go ahead.

A. Now, Mr. Examiner, Mr. Keffer has been laying great stress on---

Mr. Spencer: Wait a minute.

The Witness: —on Quadrant 3 in Hutchinson County.

Mr. Spencer: I thought maybe the witness was going to make an argument to the Examiner.

The Witness: I want to point out the reason for my statement.

Mr. Spencer: All right.

The Trial Examiner: Let me say this, Mr. Hammer, you must remember that Commission's counsel will take you back on redirect. Now, if what you are about to say is an explanation of what you have been asked on cross examination, why, perhaps you should go ahead, but if not I think we would move along much faster—

The Witness: Well, then, I think we better leave it for redirect, then, Mr. Examiner.

Mr. March: Mr. Hammer, your statements aren't complete, though, unless you make this explanation.

The Witness: That is true.

Mr. March: I think in that sense, Mr. Examiner, it is very definitely a statement which the witness wishes to make in explanation of his answers to Mr. Keffer's previous questions.

The Trial Examiner: In that situation it is perfectly all right, but I thought we might hurry this thing along a little.

Mr. Keffer: All right, if Mr. March or Mr. Lange wants to take the witness on that subject and let us have him back, why, all right. You can have your redirect now on that particular phase of it, if you want to get that in.

Mr. March: I wouldn't want to interrupt your cross examination.

Mr. Keffner: That's all right, you go right ahead.

Redirect Examination.

By Mr. March:

Q. You may make the explanation you had in mind.

Mr. Keffer: Well, that's just the same as though we had gone ahead in the first place, Mr. March. I thought you wanted to cross examine.

Mr. March: Do you want me to ask a whole bunch of little questions?

The Trial Examiner: Well, let's go ahead, Mr. Keffer, and bear this in mind, Mr. Hammer, that if you have an explanation to make, you can make that explanation, but this matter of volunteering information, I just want to call your attention to the fact that Commission's counsel will take you back on redirect and I am sure they will not overlook any of these matters.

The Witness: I think it would be better to have it that way.

The Trial Examiner: I think we will get along better.

Mr. Keffer: We really would make time, Mr. Hammer, and Mr. Examiner. There is no question about that.

Mr. March: However, Mr. Examiner, the witness can always feel free to make any explanation of his answers if he sees fit.

The Trial Examiner: That's just what I have advised him, Mr. March.

Mr. Keffer: We have always been very cooperative, I think, in allowing witnesses to make explanations when so desired.

Recross Examination (Continued)

By Mr. Keffer:

Q. All right, Mr. Hammer, you made a statement a while ago that where your isobar lines were wide and there wasn't much differential in pressure that there wasn't much migration of gas, didn't you?

A. Over long distances that is true.

Q. Well, if the isobar lines are wide apart, that follows, doesn't it?

A. What follows? What do you mean?

Q. That they are a greater distance apart than when they are close together.

A. That's right.

Q. All right, now, that depends on porosity and permeability of your formation, doesn't it, entirely?

A. Yes, on the two factors.

Q. That's right, and you don't know what either one of them is—you have said that?

A. No, I don't.

Q. And you don't know where—you don't know whether the gas migrates rapidly or not at all in that area, that you just spoke about, do you?

A. Well, the question of the rate of gas migration is a rather intricate problem.

Q. I grant you that, but you made a positive statement a while ago that it did not do a certain thing.

A. What statement?

Q. That there was no appreciable migration of gas where your isobar lines were wide as between 10-pound intervals.

A. Well, that was on the basis that your pressure differential is so small, when you consider distance, that under any ordinary conceivable condition you wouldn't have.

Q. That's right. You have admitted that if you have the porosity and the permeability you are going to get the drainage even if there is a small pressure differential?

A. That is also a relative proposition.

Q. Certainly, and you have no idea what either one of them are, either porosity or permeability, and not knowing either of them you make the positive statement that you just know that drainage doesn't occur?

A. Well, I know it, Mr. Keffer, from a configuration of a study of the isobars over a period of five years. Now, we have agreed that when that occurs it usually occurs at right angles, generally, to the horizontal position of the isobar lines themselves. Over a period of our study of the thing there is nothing to indicate in this particular case any longer period or continuous period of migration except the possi-

bility of it just along the eastern line of Quadrant 3 in Carson County over to Quadrant 2 in Carson County.

Q. All right, then it is your position that the configuration of your isobar lines indicate to you that the drainage matter is just now hitting Canadian River?

A. Why, Canadian River hasn't any acreage over in there.

Q. In Carson County—

A. In Quadrant 2 and 3, Carson County.

Q. Well, I am—no, not in 2 and 3, that's quite right. We were over at Borger a while ago, coming back towards Canadian River and I thought that we were yet. I hadn't left that area yet. Let's get back to the Canadian River area. That's what we are talking about. We left the other long ago.

There is drainage from Canadian River to the northeastward. There can't be any question about it on your isobar lines, can there?

A. Well, they indicate a lower pressure in that direction, certainly.

Q. The gas travels from high pressure to low pressure areas, doesn't it?

A. That again is a relative proposition.

Q. Did you ever know it to fail to do it?

A. Well, but the rate is a relative proposition.

Q. All right, the rate depends upon porosity and permeability and pressure differential, doesn't it?

A. That's right.

Q. You know what pressure differential is; you haven't any idea as to permeability or porosity?

A. No.

Q. You have only one of the three things you must know to determine that, haven't you?

A. Well, I think that question will be answered later.

Q. Why not answer it now?

A. Well, because I would just request to come back here and reserve a statement.

Q. Do what?

A. Reserve a statement.

Q. What do you mean by reserve a statement?

A. Well, the Examiner himself suggested that I reserve a statement—

Mr. Keffer: I don't quite—

The Trial Examiner: You understand at that time, Mr. Hammer, I qualified that to the extent that I thought it would be best for you not to volunteer information which Mr. Keffer had not inquired on; that is, on matters on which Mr. Keffer had not inquired, but he is getting down to it now.

The Witness: No, that's just the point, he hasn't got down to it.

Mr. Keffer: Read the question.

(The question referred to was read by the reporter, as set forth above.)

The Witness: Except certain definite facts, aside from the question of permeability or pressure.

By Mr. Keffer:

Q. All right, what are those certain definite facts?

A. That's the thing I was going to do a while ago and I will do it now.

Mr. March: He may mention them now.

By Mr. Keffer:

Q. All right, go right ahead.

A. Now, the facts of the case are, and we have agreed on it, that—

Q. Who—you and me?

A. You and I.

Q All right.

A. —that the Borger area was originally discovered around the fall of 1925 and the active development started in 1926.

Q. That is true, we are agreed.

A. And that it continued and spread out from that point, that it was a big prolific field. We admit that during that time there was a lot of wastage of gas. We have had no argument on that. We also agreed that because of that wastage and subsequent withdrawals there had been a low pressure area developed.

Now, we have agreed on that. There is no argument about that.

Q. That's right.

A. But here is something that is very important, and that is this: Notwithstanding the fact that that low pressure area was in existence there, starting in 1926—well, I wouldn't want to say what year—it reached its maximum, but for many years it has existed there as a low pressure area and notwithstanding that fact, right here in your Quadrant 1 in Potter County in 1935 you still had a weighted average pressure in that quadrant of 419.8 pounds, and also in 1939 as of August, 1939, you still had a weighted average pressure for that quadrant of 402 pounds, a drop as between 1935 and 1939 in weighted pressure of only 17 pounds, or an average annual drop of 3.4 pounds.

Now, from 1922 when Canadian River first started to take gas—

Q. Canadian River? No, they didn't start then.

A. Well, Amarillo Oil Company.

At least, regardless of the company, when gas first started to be taken out of there, naturally I think we will all agree that the pressure was 430 pounds. Now, by 1935, or from 1922 to 1935, there had only been a pressure drop—I am talking about weighted pressure now all the time—of 13.2 pounds over a period of 13 years, or an annual drop of 0.78 pounds per year—7/10ths of a pound, from the beginning up to 1935.

Now, from 1922 to 1939 and taking your original field pressure at 430 pounds, there had been only a total drop in weighted pressure from field original pressure to 1939 of 27.2 pounds, for a period of 17 years, or an average of 1.6 pounds per year.

Now we'll take the same general condition for Hutchinson, Quadrant 3. We can't start in 1922 because we have to start at the period of development and for the purpose the tabulation I have just used 1926 because that is virtually when it started. In Hutchinson 3, Quadrant 3, the original pressure we'll say before the discovery well was 430 pounds. In 1935 the weighted pressure was 295 pounds, a difference in

pressure of 1935 pounds over a period of 9 years, or an average annual decline in weighted pressure of 15 pounds.

Now, between 1926 and 1939, assuming the original field pressure at 430 and the terminal areal pressure—or the areal pressure, weighted pressure for 1939 at 270.6 pounds.

Q. Where?

A. We are talking now about Hutchinson, Quadrant 3—or a difference of 159.4 pounds in weighted pressure over a period of 13 years, or an average annual decline in weighted pressure of 12.26 pounds.

Now we will take the same period that we took in the other one, I mean that we took in reference to the other one. We utilized the 1935 to 1939 data. In 1935 the weighted areal pressure for Quadrant 3, Hutchinson County, was 270.6 pounds—no, I beg your pardon. The weighted pressure for 1935 was 295 pounds and the weighted pressure for 1939 was 270.6 pounds, or a decline of 24 pounds over a period of five years, or a decline of 4.9 pounds average over a period of five years.

Now, the point there is, and the reason the tabulations have been made is that notwithstanding that we have agreed and know there is a low pressure area that has continued to exist there and that is still there, that over the period from the beginning of the field up to 1939 it had had no appreciable effect whatsoever on the decline in weighted pressure for the area in Potter Quadrant 1

Q. Is that all of your statement?

A. That's right.

Q. All right. Now, you were talking about what quadrant in Hutchinson county?

A. 3.

Q. 3. You didn't take Quadrant 2 in Hutchison County, did you?

A. No, not in this case.

Q. No, that's right. What do your isobar lines show with respect to Quadrant 3 in Hutchison County?

A. Well, it shows that the pressure is toward the low pressure area.

Q. That's right, that it is losing some gas into the Borger area, isn't it?

A. No, not over the five-year period that we studied.

Q. Well, what would you get right up that way?

A. That's what I pointed out the other day, that between the Borger field proper and Sanford area over here, that area in between those two, the pressure has remained practically at a constant—yes, the pressure isobars have remained almost constant over a five-year period.

Q. Well, what's that?

A. And the drainage—

Mr. March: When you say "what's that?" what do you mean, Mr. Keffer?

Mr. Keffer: He knows.

Mr. March: I know, but the record won't show it.

Mr. Keffer: I know, but I didn't want it to show. I was calling Mr. Hammer's attention to a matter which he had overlooked and I didn't want to embarrass him by putting it in the record. Now since you have brought it out in the open I will state that I was pointing to the very definite drainage from Quadrant 3 in Hutchinson to Quadrant 2 in Hutchinson County, and Mr. Hammer just said there was none and that the reason—

The Witness: Did I say there was none whatsoever?

Mr. Keffer: I understood you to.

The Witness: What does the record show?

(The record referred to was read by the reporter as set forth above.)

By Mr. Keffer:

Q. Well, that is indicating drainage in Quadrant 3 into Quadrant 2 in Hutchinson County, was it not?

A. Indicating the position of the isobars.

Q. Well, then, the position of the isobars indicated drainage, did it not, as I have just stated?

A. The position of the isobars do indicate drainage but the position of isobars do not always indicate drainage over any large distance, and in this case it is true there are wells between two indicated points that they themselves are taking gas out of the reservoir. Because you happen to have

an indicated decline in isobars or pressures doesn't necessarily mean that that gas is all migrating across. These wells intervening always get their share of the gas and are largely responsible for the pressure decline.

Q. How do you know they are largely responsible?

A. Well, they take out a lot of gas.

Q. That's right, but how much more gas is passing through?

A. Well, in an intensely drilled area such as that Borger area there isn't a great deal of chance of long distance migration.

Q. Well, what determines how much gas is passing through?

A. Well, that is indeterminable.

Q. No, what are the factors that cause it to pass through and influence the rate?

A. Well, we have repeated that so many times.

Q. One more time, please.

A. It is always a pressure differential, of course—

Q. Pressure differential, porosity and permeability, isn't it?

A. Yes, relatively speaking, yes.

Q. All right, under here you have a pressure differential here, haven't you (indicating)?

A. Where are you talking about?

Q. The southeast part of Quadrant 3 in Hutchinson County and the southwest part of Quadrant 2 in Hutchinson County.

A. Yes, the isobars are relatively close together there.

Q. All right, then, what do you say about your permeability, then, and porosity? You don't know, do you?

A. I do say this, though.

Q. Answer my question first. Do you know what the porosity and permeability is there?

A. I don't and neither does anybody else.

Q. All right, and you made no effort to find out?

A. No.

Q. All right, go ahead.

A. But as far as migrating from this corner here (indicating) into the Borger field proper, here is a highly developed area in the southwest corner of Quadrant 2, Hutchinson County. There are a large number of wells in there,

closely spaced, which would probably take care of any drainage at all that might come from Carson—the western part of Quadrant 3 in Carson, or from Quadrant 3 in Hutchinson, the southwest corner of Quadrant 3 in Hutchinson to that area, so that local migration of that type does affect the situation.

Q. All right, that's all I want to know. There is drainage out of Quadrant 3 into Quadrant 2. It doesn't matter which wells they drain to, there is drainage from one quadrant to the other?

A. Well, over a period of years that condition has not materially changed and it is a minor consideration.

The Trial Examiner: Well, is there drainage, Mr. Hammer?

The Witness: Well, it is very questionable whether there is any. It is entirely, Mr. Examiner, a question of relative interpretation.

By Mr. Keffer:

Q. Mr. Hammer, you just said the drainage was coming from Quadrant 3, Hutchinson, and Quadrant 3 in Carson, was being caused by wells in the southwest portion of Quadrant 2.

A. Wait a minute, let's localize that statement. I didn't indicate the whole quadrant in either case.

Q. No, I know you didn't.

A. I stated that in the extreme southeastern corner of Quadrant 3 in Hutchinson and the extreme northwestern corner of Quadrant 3 in Carson there was indicated drainage there locally into a highly developed area in the southwest corner of Quadrant 2 in Hutchinson County.

Q. All right, then, your answer is there is drainage from Quadrant 3, Hutchinson, to Quadrant 2, Hutchinson?

A. In a minor part, in relation to the entire quadrant, yes, but it is a minor consideration.

Q. All right. Now, you don't know what the porosity or permeability is that might influence it in there? I think you already answered that. Strike it. I won't embarrass you by asking you the same question.

A. You aren't embarrassing me any.

Q. Now coming to Quadrant 3 we have a very much different situation, haven't we?

A. Quadrant 3 where?

Q. Hutchinson, as compared to Quadrant 1 in Moore County.

A. Well, different in one respect, between what?

Q. Your isobar lines.

A. Well, you are comparing the two. You say we have a different question—

Q. I said compared to Quadrant 1 in Moore County.

A. Well, now you are comparing what—Quadrant 3 in Hutchinson and Quadrant 1 in Moore?

Q. I say, we have a much different situation with respect—I will illustrate it this way—with respect to drainage in Quadrant 3, Hutchinson County, out of Quadrant 1, Moore County.

A. Compared to what?

Q. Compared to drainage out of section—out of Quadrant 3, Hutchinson, into Quadrant 2, Hutchinson, or vice versa.

A. Yes, there is a difference. There is a different condition there.

Q. Well, it is rather substantial, don't you think?

A. Well, there is a different condition.

Q. Just tell us what condition you find there?

A. As to the position of the isobars—

Q. Well, let me state it. I think it would save time.

You take Quadrant 3 of Hutchinson County. You find a very decided pressure differential between that area generally and Quadrant 1 of Moore County to the westward, don't you, a difference I would say of at least 70 pounds starting from about the center where the word "three" is written on the Canadian River of Quadrant 3 over to the west line of the county, a distance of maybe four or five miles?

A. That is what the map shows.

Q. That is what the map shows. All right, you get on out into Moore County and you have 1, 2, 3, 4, 5, 6, 7,—well, we'll say 7—a difference of 70 pounds from the east side of Quadrant 1 in Moore County out to about the center of it generally, about where the figure 1 is. Does that seem to be about right?

A. Well, if you counted them right.

Q. All right, will you count them? I counted them hurriedly.

A. I would say that there are seven isobars.

Q. Yes. I counted seven but counted them hurriedly.

So you have a pressure differential about the center point east and west of Quadrant 1, Moore County, to about the center point east and west of Quadrant 3, Hutchinson County, of perhaps 140 pounds, haven't you?

A. With the exception that you have in Quadrant 1, Moore County, and in Quadrant 4—no, Quadrant 6, Moore County, two local high pressure areas which in both cases have arrested the movement of gas eastward and at least part of the gas is draining into low pressure areas to the west.

Q. All right, this high pressure area you refer to in Moore County, Quadrant 1, is very isolated, very small, isn't it?

A. Well, it exists and it is still there.

Q. I know, but as you show it on the map, you show it less than 640 acres in extent, don't you?

A. The fact remains that it is a barrier there locally.

Q. Answer my question.

A. Nearly. Approximately.

Q. Near the west side of the quadrant. How is that going to affect the drainage from the center?

A. It is not going to affect the drainage. The point is it does affect it in the northern part.

Q. Very little in the northern part because it is so small.

A. It has been there consistently over a five-year period and it is still there, or was still there when we made this map.

Q. All right, don't you know what this is?

A. Well, it is a high pressure area.

Q. How's that?

A. Well, the well is a high pressure well.

Q. Do you know what a "tight" is, a little local "tight"?

A. Yes.

Q. All right, you get a big well here and then drill over there 330 feet and maybe get a small well. What ordinarily

in a field of the characteristics of the Panhandle, what does that mean?

A. In general you would say it was an area of low permeability.

Q. All right, and then you go on. This was the big well. I said 330 feet, I'll make it 660—was a small well, and then beyond that was another big well, another 660 feet. Now, what would that indicate to you?

A. Well, it would indicate an area of perhaps—relatively speaking, it would indicate an area of larger permeability.

Q. Yes, but that well in between that small well where you hit what oil men call a "tight" spot, since you have got big wells around it would indicate a very small, tight area there, wouldn't it?

A. That's just the point. That's important there. If you have—

Q. Wait a minute. Answer my question first. You say yes?

A. I say yes, and that is very important there.

Q. All right.

A. If that is an area of low permeability, certainly gas is not going to migrate across it rapidly to the east.

Q. That's right, and if it covers less than a section, as your map shows, and I presume you made it as big as you conscientiously could—a section in a county is not very much, is it?—a section in a quadrant isn't very much?

A. No, not very much.

Q. Well, all right, now, you do have a very decided migration of gas as shown by your isobar maps from Quadrant 1, Moore County, into Quadrant 3, Hutchinson County?

A. In the northern part of the quadrant, no.

Q. All right, the south half?

A. In the south half there is an indicated gradient in that direction.

Q. Rather substantial?

A. It is rather substantial.

Q. All right. When reading your pressure declines in Quadrant 3 a while ago, that meant absolutely nothing.

A. What?

Q. Reading pressure declines over a period of years in Quadrant 3 in Hutchinson County, isn't that what you did?

A. I don't get your—

Q. When you made that speech of ten minutes a while ago, reading all those pressure declines into the record on Quadrant 3, Hutchinson County, making quite a point of it. Well, there wasn't any point to it, was there?

A. Yes, there was, and I can do the same thing, and I intend to do the same thing for the quadrant you are talking about.

Q. All right, that will be very interesting, Mr. Hammer.

If I can show you areas in Quadrant 3, Hutchinson County, a number of wells where the pressures are actually increasing while those wells are producing substantial volumes of gas, then that would mean to you, I think you said the other day, that that would mean that those wells were being repressured by drainage from other sources?

A. No, I didn't make that statement. I made the statement about repressuring that the Huber Corporation had done some repressuring in that area.

Q. Oh, we weren't talking about the same thing. Where did they get the gas to use?

A. They took it out of the ground and put it back in locally.

Q. Took it out of wells 600 feet away and put it in this one?

A. Locally, that's right.

Q. How can you figure by any stretch of the imagination that it is going to affect the pressure there by taking it out of one well and putting it back into another?

A. It simply means that if there weren't withdrawals, that they took the gas out and naturally when they took the gas out there was a proportionate decline.

Q. Going right back immediately?

A. All right, then they put the gas back in.

Q. Yes.

A. Having done that it will help to maintain that pressure in there. Certainly when you put gas back into the ground it helps to maintain the pressure.

Q. I see what you're talking about. All right. If I can show areas in there where that is not happening, where there is no mechanical repressuring, and wells that are producing lots of gas and you had increase in your pressure,

then what would that mean to you? Wouldn't that mean that they were being repressured by natural means by reason of drainage from some other source to the point of production?

A. It might entirely be a local source.

Q. What do you mean, a local source?

Other wells are producing down there, too. Keep your story straight, Mr. Hammer.

You get to the point many times, we'll say this isobar line where it is caused by local sources and then you get down here into another situation where there is drainage and then you say that is entirely local.

Now, those two things are rather inconsistent, aren't they?

A. No, I don't think so.

Q. All right, we'll let the record stand in that respect.

I believe, Mr. Examiner, that if we might recess for the noon hour that perhaps I could expedite the matter somewhat.

Mr. Lange: That is agreeable.

The Trial Examiner: Very well, Mr. Keffer.

The hearing will stand in recess until 2:00 o'clock this afternoon.

(Whereupon, at 12:30 o'clock, p. m., a recess was taken until 2:00 o'clock p. m., of the same day.)

Afternoon Session, 2:00 p. m.

The Trial Examiner: The hearing will be in order.

Mr. Lange: Mr. Examiner, we have some corrections that have been signed by counsel covering all of the volumes through XL.

The Trial Examiner: Fine, Mr. Lange.

Whereupon—

A. A. HAMMER, the witness on the stand at the time of

adjournment, having been previously duly sworn, resumed the stand and testified further as follows:

Mr. March: Now, Mr. Examiner, Mr. Keffer made two requests for information to be furnished by this witness. The first was that Mr. Keffer wanted to know as to any statement made by the Railroad Commission of the State of Texas regarding the east and west field.

Will you read what you have from the annual report of the Texas Railroad Commission regarding that, Mr. Hammer, stating what report you are reading from and the page number?

The Witness: This is the Railroad Commission's report, of Texas, Ernest O. Thompson, Chairman; Lon A. Smith and C. V. Terrell, Commissioners. It is entitled "Annual Report on the Panhandle Oil & Gas Field, July 1938," by Oil and Gas Division, Engineering Department, November 1938, V. E. Cottingham, Director of Production.

On Page 4 of that report the following statement is made:

"An intervening structural restriction does not permit the free intermingling of gas, and the corresponding equalization of pressures, between the east part of the field and the west part of the field.

"This structural restriction resulted from a down-faulted block that occurs south of an east-west fault which roughly coincides with the north boundary line of the ACH & B Survey, and extends for a distance of approximately ten miles.

"Along the south side of this fault, the corresponding pay horizons have been faulted down below the water level, thus preventing the migration of gas through this down-faulted block from one field or zone to the other. North of this fault is a narrow strip of production which has been drilled to a density of approximately one well to ten acres.

"As a result of the heavy withdrawals from these oil wells, a low pressure area has been established which effectively impedes the flow of gas through these formations between the east and west zones.

"All of the gas in the east zone or field is sweet. The gas in the west zone is both sweet and sour, with sour gas occurring along a belt skirting the north flank of the Panhandle structure."

Mr. March: There was another request made by Mr. Keffer. Will you state what that is and state the information you were able to get?

The Witness: Please read that question.

(The question referred to was read by the reporter as set forth above.)

The Witness: As I understood Mr. Keffer's request, he wanted a statement of the ultimate reserves—when I say "ultimate," I mean the original reserves at 430 pounds pressure.

The Trial Examiner: The original reserves in place?

The Witness: Underneath the acreage, yes.

I have a tabulation here that I made some time ago showing not only the original reserves underneath Canadian River's acreage but the original reserves underneath the entire quadrant or quadrants in which the Canadian River has acreage. I noticed when I finally found this tabulation today at noon that the ultimate reserve by quadrants is calculated down to zero pounds. In other words, zero well head by quadrants, but there is a calculation of it, of the total of all quadrants down to 25-pound well head gauge. That is for both the Canadian River acreage and the total acreage in all of the quadrants in which Canadian River owns acreage.

Recross Examination (Continued).

By Mr. Keffer:

Q. Will you let us have that statement Mr. Hammer?
A. Yes.
Q. Will you let me see the Railroad Commission's report you just read from, Mr. Hammer?
A. Yes.
Q. That report was for what year?
A. 1938.

Q. 1938?

A. Yes.

Q. Now on the report that you just read from Mr. Hammer, there is nothing in that that shows that the east part of the Panhandle field and the west part of the Panhandle field are separate fields, is there?

A. It shows to all intents and purposes that they are separate fields.

Q. You didn't even draw your isobar lines showing separate fields, did you?

A. No, I didn't.

Q. And the Railroad Commission doesn't do it either?

A. I don't recall.

Q. You have seen their pressure map, Mr. Hammer?

A. Yes, but I wouldn't recall exactly.

Q. All right, you say there is a fault in this area indicated as ACH & B in Gray County?

A. Yes.

Q. It dips down where you have water encroachment?

A. Not necessarily water encroachment.

Q. How do you account for this producing horizon you show along the south of that?

A. As a matter of fact up to the time of 1939 in August while there were a few wells drilled in there, it is my very definite remembrance—I think I can truthfully say that there were none of these wells connected—

Mr. March: Identify that, please.

The Witness: That's in Gray County, Quadrant 5, and the area lying south of the structural depression as indicated on this isobaric map.

By Mr. Keffer:

Q. Well, now, the map shows very clearly that there is a connection between the east and the west field south of the fault, even though the statement you read from the Railroad Commission report indicated there was not?

A. No, it doesn't at all.

Q. I thought it indicated that. Well, you have read it. It speaks for itself.

Well, then, there is a connection—

The Trial Examiner: Pardon me, Mr. Keffer. Mr. Hammer, were you speaking of the map or of the report?

The Witness: At first I read the report to state exactly what the Railroad Commission said about it.

By Mr. Keffer:

Q. I know, but the Railroad Commission wasn't as clear to my mind at least as it might be. All right, now, we were talking about the fault along the south side of this fault that is this way (indicating).

Mr. March: Which way?

Mr. Keffer: South, as shown on the map, toward the bottom, the fault is indicated, that has the word "Gray" written in there on the map, Exhibit 179, indicated as a barren island in there, so to speak.

The Witness: Structural depression.

By Mr. Keffer:

Q. Yes. Now, that is the fault the Railroad Commission is speaking about?

A. No, the fault they are speaking about is this one up here, this line, as they state, through ACH & B Survey.

Q. Then south of the fault, if you go far enough south, there is a connection between the east field and the west field?

A. I think it is very definite, Mr. Keffer, that if the Texas Railroad Commission had thought that there was a passage for gas through there they would have so stated and they did not.

Q. I grant you that. I am taking your own map, Mr. Hammer, and asking you what it shows.

A. It shows that what few wells were drilled in there were wells of such character that no one having a pipe line felt justified in connecting them up.

Q. Why?

A. Well, because of low permeability, perhaps.

Q. What is low permeability? What does low permeability mean?

A. Wait a minute. I want to finish answering this question. Also this area right through here running from

Lefors south is structurally in relation to the west part of the field and the east part of the field, is a structuraly low area. Now, I did not make a structure map, but I did take enough logs in this general area to indicate to me that there is a low structural area there, a higher structural area here, over in Wheeler County, and another structurally high point beginning west of this area south of Lefors and extending on west until the high point is reached some place in Moore County.

Q. All right, Mr. Hammer. Now back again to the area—what is this quadrant?

A. That is Quadrant 5.

Q. That includes the barren space as well as that below?

A. Yes.

Mr. March: In Gray County.

The Witness: I might say, Mr. Keffer, in arriving at the area this was drawn out. It was not included.

By Mr. Keffer:

Q. You did not count the acreage as shown in the white?

A. No.

Q. But down where your isobar lines are you did compute that acreage and that is in Quadrant 5?

A. That is right.

Q. Now, you said those wells were small. I thought you said a number of times you didn't know the size of the wells in the Panhandle field and paid no attention to them.

A. That was an abstract thing. In certain cases like this when you want to find out reasons for some certain thing, why, naturally you would pay some attention.

Q. I thought so.

A. But as to the whole field, that was a different problem. Here was a special problem.

Q. You weren't interested in any part of the field, interested enough to observe potentials except that part in Gray County that you have referred to, is that right?

A. Except in an abstract way.

Q. What do you mean, in an abstract way?

A. Just in a general way.

Q. How was that?

A. I said, just in a general way.

Q. Generally, then, you know where the large wells are in the field, don't you?

A. In a general way, yes.

Q. Well, you know specifically in that spot?

A. Yes, and there was a reason for finding that out.

Q. Well, if you found areas where there were big wells, wasn't there some reason to find out why they were big?

A. No particular reason.

Q. Why wouldn't there be just as much reason to find out where there was a big well why it was big as to find out on a little well why it was little?

A. Well, the whole point is that I knew about this statement that was made by the Railroad Commission and I wanted to check to see additional reasons, if any, why they were, and I found them. Now, as I stated a while ago, if the Texas Railroad Commission had believed that there was any chance of gas passing across this area of low permeability south of that depression they would have so stated.

Q. All right, now you stated this morning that you weren't going to hazard a guess what the Texas Railroad Commission believed about anything. You absolutely refused to do that. Now you are quoting their belief.

A. I said if they believed it they would have so stated.

Mr. March: Let the record show a request was made to prove where the Railroad Commission made any statement in regard to the separation of the east and west field.

Mr. Keffer: All right, I appreciate that. I am trying to run the thing on down, Mr. March, that's all.

Q. All right, now I take it that if you were interested in five small wells in Quadrant 5 in Gray County you were interested in small wells all over the field.

A. Not particularly. I wasn't interested in them all over the field particularly. I was interested in certain small wells in Wheeler County. In areas, for example, where the wells had not been connected up, and naturally when I came to a thing like that I would wonder why.

Q. That's right.

A. And I would try to check to find out.

Q. All right, now, you found small wells out here in Potter County near the fault line, didn't you?

A. I don't recall any from memory, those wells, no.

Q. You found small wells down in Hartley County, didn't you?

A. Again I say I don't recall as to the potentiality of those wells.

Q. You found some small wells up in northwestern Hutchinson County, didn't you?

A. I don't remember the open flows up there.

Q. You just remember them in one spot, but you have got a pretty good recollection of them there, is that the status of the matter?

A. It was the only place where I had any reason to.

Q. All right now, Mr. Hammer, you stated that this was an area of low permeability.

A. I said indicated low permeability. At least that's what I meant to say.

Q. You think that it is, is that your opinion about it?

A. Yes.

Q. What do you base it upon?

A. Well, I base it largely upon the fact that the wells in that area are very very small.

Q. Suppose they had been very very large, then what would have been your opinion?

A. Well, if they had been large wells they would have been connected up, unquestionably.

Q. I am talking about permeability, I am not talking about connections.

A. Well, if the wells had been large the permeability might have been small or the permeability might have been large.

Q. Now, let's be consistent about it. If a small well indicates low permeability, why wouldn't a big well indicate a high permeability?

A. Well, in general a big well will.

Q. Now, in general—don't you know that you would have to have high permeability to have a big well, Mr. Hammer?

A. Immediately surrounding the particular well, yes.

Q. All right. Then, if you found—of course, you didn't make any study and didn't find,—but if you found in the south part of Moore County and the north part of Potter County big wells, what would that indicate as to perme-

ability? Just follow your question on out. Don't change your answer on it.

A. Well, it would have indicated that those wells were in an area of relatively large permeability surrounding each well.

Q. That's right. Then if all of them generally are large, why, the area then has a rather high permeability, doesn't it?

A. That would be a fair assumption.

Q. Well, isn't it a correct assumption?

A. Well, not in all cases, I wouldn't say that it was.

Q. All right, if you don't want to say so—now, if that is an area of high permeability then gas migrates at a more rapid pace than it does in a field where the permeability is low, doesn't it?

A. Again that depends upon the question of pressure differential.

Q. All right, take a given pressure differential, and pressure differential you want to take, just so it is constant.

A. It also depends on—

Q. Answer my question.

A. What is his question?

(The question referred to was read by the reporter, as set forth above.)

The Witness: Again I use the word "relatively," yes.

By Mr. Keffer:

Q. All right, that is as strong as you want to go?

A. That is as strong as I will g..

Q. I suspect that's strong enough, anyway.

Now, Mr. Hammer, I went into a matter this morning as to Gray County more or less at random, and I want to take one of the quadrants in Moore County and go into it more specifically. Will you take your exhibit—I guess it's 180—and look on Page 5, Table 3?

Before I get to that, I really hadn't finished Wheeler County, but I am coming to that next. You say that the area south of the fault which you have referred to and which the Railroad Commission has referred to in Wheeler County—north of the fault, let's take that area just north

of the fault which I take it is included in your Quadrant No. 7, Gray County, is that correct?

A. Yes, that is correct.

Q. Now, as a matter of fact, the area north of that fault line has been an area of high gas production, has it not?

A. Yes, it has produced a lot of gas.

Q. They have big wells in there, haven't they, a number of them, at least?

A. Yes.

Q. And they have produced large volumes of gas.

A. In times past, yes.

Q. Yes, that is in the Lefors area, the casing heard carbon black center in the Panhandle field, isn't it?

A. I think there used to be; some of them are gone now.

Q. Why gone?

A. Well, because the gas in that particular local area probably is exhausted.

Q. Now, you have a low pressure area in there, haven't you?

A. That's right.

Q. All right, now, gas drained from west of that low pressure area from the westward into it—

A. From the westward of that low pressure area from—from the westward of Lefors?

Q. Yes, out in here. You don't show any line in there at all, it is so low, across here?

A. That would be a very questionable assumption.

Q. What's questionable about it?

A. Well, here is a higher pressure area just north of this fault line and coming up against the fault line, higher than the north of Lefors.

Q. What would be the direction of the migration of gas from this higher pressure area you are talking about into the lower pressure area?

A. It would be going into the north.

Q. Migrate into it, wouldn't it?

A. Yes.

Q. And we have a situation where gas to some degree at least could migrate from the west area into the depression around Lefors and could likewise migrate from the east-

ward into the depression around Lefors. It can come both ways. It has to meet from the two sections.

A. However, it is the opinion of the Texas Railroad Commission that gas from the east of that area doesn't move over to the west.

Q. The Railroad Commission didn't say that?

A. Oh, yes, it did. Read it.

Q. All right, here's what they say:

"As a result of heavy withdrawals from the oil wells, a low pressure area has been established which effectively impedes the flow of gas through these formations between the east and west zones."

A. All right, it says it effectively impedes.

Q. All right, we weren't talking about gas going across it. We were talking about gas going into it from the east and also coming into it from the west. Now, there is nothing in there that says that doesn't happen, is there?

A. In a purely localized condition it would happen.

Q. You say "localized." You have been using that a lot. Just what do you mean by "localized"?

A. Well, just as the isobar there indicates, a local condition.

Q. Define that local condition.

A. Well, actually the great number of oil wells that exist in this area, that have not been isobarred—

Mr. March: Describe it a little more fully.

The Witness: That is in the southwest part of Quadrant 7, Gray County, and the southeast corner of Quadrant 8, Gray County, and the northeast corner of Quadrant 4 in Gray County.

By Mr. Keffer:

Q. Why didn't you run your isobar lines on out there?

A. Because there were no details given in the Texas Railroad Commission—no data to work on.

Q. This is a new gas field and as you stated large volumes of gas have been produced?

A. That's right.

Q. All right, I think that is enough on that.

Now, referring to your Exhibit 180, Mr. Hammer, let's look again at Quadrant 1 in Moore County—no, Potter County.

All right, I had it almost right—going to Potter County, 1, the area that I am pointing to here on the map, when you considered that quadrant as such you got a weighted—that is, an acre pound factor of 58.92, didn't you?

A. Potter 1?

Q. 58.92.

A. 58.97.

Q. All right, that's near enough, 58.97. When you considered Moore 1 in connection with Potter 1, you got what—47.88, wasn't it?

A. 47.88, that's right.

Q. And when you considered Moore 2 in connection with Potter 1 you got in Potter 1 36.82, didn't you?

A. Now, wait a minute. Let's see if I understand what you want.

Q. Just what I asked.

A. Now, I don't understand.

Q. All right, when you were determining what was in Moore 2 you also considered Potter 1?

A. It was grouped together.

Q. That's right. At that time you gave Potter 1 a value of 36.82, didn't you?

A. You are talking about Potter 1?

Q. That's right, yes, sir.

The Trial Examiner: What you are asking for is the Moore 2?

Mr. Keffer: No, I am asking the different weights that he gave Potter 1 each time he made a different calculation.

The Trial Examiner: For another quadrant?

Mr. Keffer: That's right.

The Trial Examiner: I don't think he understands that.

Do you understand that, Mr. Hammer?

The Witness: No, I don't. I think there is some confusion here but I don't get it.

Mr. Keffer: Let's straighten it out. We'll wait until you get it.

The Witness: In the final analysis, on Page 6, Tables 4 and 5, Exhibit 180, the production per acre pound there for Potter 1 is 58.97.

By Mr. Keffer:

Q. In consideration with what?

A. What?

Q. In consideration with what?

A. Well, that is the production per acre pound that was arrived at by grouping the—by the group method of arriving at a fair figure for production per acre under—

Q. I know, but that isn't what I have been asking you.

A. That is the condition, whether you have been asking it or not.

Q. Well, let's start all over again. Maybe I can simplify it a little bit.

How many times did you use Potter County 1 when you were computing the value of other quadrants?

A. It was utilized on five occasions.

Q. That's right. All right, now, when you were arriving at what its relative weight was, or its per acre content, or acre pounds decline was—I'll get it right yet—when you were figuring for Potter County 1 as such, you got 58.97, didn't you?

A. That's right.

Q. And when you were figuring Moore County 1, you gave Potter County 1, 47.88, didn't you?

A. No, I didn't do that at all.

Q. All right, what value did you give to the area which included Potter 1 when you were figuring the Moore 2?

A. All right.

Q. Just answer my question. That's all I want.

A. I am going to.

Q. No, you got 47.88. Say "47.88," then you have answered my question.

A. For what?

Q. For what you gave to the area which included Potter 1, which included every acre in Potter 1—47.88.

A. In Potter 1?

Q. Potter 1.

A. No, 58.97.

Q. No, that was Potter 1 considering it alone, not alone, but considering or determining the remaining reserves in Potter 1. That's what you figured it was based on, a factor of 58.97.

A. That's right.

Q. You can follow me on this. It isn't difficult.

Now, when you came back to determine what it was in Moore County 1, just to the north of it, then you gave Potter County 1 a different value, didn't you?

A. No, no, no, no, no, I didn't do anything of the kind.

Q. All right, you gave the area a different value, didn't you?

A. I simply utilized Quadrant 1 in Potter 2—

Q. Let's don't go over all that again.

The Trial Examiner: Mr. Hammer, there is no necessity for going through all that again. What Mr. Keffer is trying to get at now, you have used Potter 1 on five occasions when you were determining reserves under the quadrant—

The Witness: Under adjacent quadrants.

The Trial Examiner: That's right, and what he wants to know is not what reserves you assigned to Potter 1, but what reserves—or what reserve was attributed to Potter 1 as a part of the total area you considered as apart in reaching your result on these other quadrants.

The Witness: That's just the point.

The Trial Examiner: That is not what you are doing.

The Witness: That is the point I am trying to make, that each one of these, the value for each quadrant was calculated independently by taking the summation of the factors in adjoining quadrants.

The Trial Examiner: The record is very clear on that.

The Witness: We didn't use any independent—we didn't group these after we had got a production per acre pound. We used them before that independently and arrived at a production per acre pound for each quadrant in relation to its adjacent areas. Now, I don't find any such figure that Mr. Keffer is talking about.

By Mr. Keffer:

Q. You will find it exactly as I will state it to you. You follow me.

Mr. March: Not the description that you give.

Mr. Keffer: Maybe you can help on the description. I would appreciate it.

Mr. March: Maybe you can describe the figure and maybe he can answer it right off. Come and show him the figure you want. Take the exhibit.

By Mr. Keffer:

Q. You have considered Potter, Quadrant 1 on five different calculations, as you have stated.

A. It has been grouped with that many.

Q. Five different groupings, I'll put it that way.

A. All right.

Q. All right. Now, when you were considering Potter 1 as such you got a factor of 58.97, didn't you?

A. Yes, 58—considering it as such.

Q. As such, yes.

A. That is the figure at which we arrived from the grouping of the acreage to apply to Potter 1.

Q. That's right. I understand that perfectly. Now, when you made your next calculation on it which involved Moore County, Quadrant 1, that time the acreage in Potter County, Quadrant 1, had a value of 47.88.

A. No, that is not at all right.

Q. Well, tell me what's wrong with it.

Mr. Spencer: All the acreage in the quadrant including that in Potter 1, had that value?

The Witness: Yes, the grouped acreage.

Mr. Spencer: That's right.

By Mr. Keffer:

Q. That's right. Well, that included Potter 1, and Potter 1 had the same value on your computation as all of the acres in the group, in that particular computation, didn't it?

A. No, not at all.

Q. Well, Mr. Hammer, when you figured Moore County 1, you took into account Potter County 1, didn't you?

A. Yes.

Q. And Moore County 2?

A. That's right.

Q. And Hutchinson County 3?

A. That's right.

Q. And Moore County 6?

A. That's right.

Q. I don't know whether you took in Potter County 2 or not.

A. I did.

Q. I take it that would be all of them. I am not checking it from the record but just looking at the map here.

All right, what was the value of all of the acreage in that group of quadrants?

A. To arrive at a production per acre pound for Moore Quadrant 1.

Q. 47.88, wasn't it?

Mr. March: Let him answer it.

The Witness: Well, let's see—47.88.

By Mr. Keffer:

Q. Now, you assigned that value in order to get your value of Moore County 1 to every acre in that group of quadrants, didn't you?

A. No, I arrived at that figure as the average for the total group.

Q. That's right, and applied it to every acre in the group without any distinction in making your average to get a figure for Moore County 1?

A. That's right.

Q. Then you necessarily in that computation assumed that Potter County 1 had 47.88?

A. No, I didn't, no, not at all, because you lose sight of these various groupings that were utilized.

Q. No, I don't lose sight of them at all.

A. When you throw out—

Q. If you don't like the manner in which I stated the question, let me state it this way:

When you made your computation and got your average that applies for the purpose of that computation, you applied it to every acre in those group quadrants?

A. It was the average production per acre pound determined for that group.

Q. That's right, that's what I have been talking about, that is, for every acre in the group the average, taking all of the acreage in the group?

A. That's all right as far as this particular quadrant is concerned.

Q. All right, you are asking the answer for quadrant 1, I know, but you had to find the average weight in all those quadrants and that figure was 47.88?

A. All right, that applies as far as arriving at that is concerned.

Mr. March: Identify it.

Mr. Keffer: Wait a minute—on the average, as a whole, which included Potter County 1, you necessarily in that computation assigned 47.88 to Potter County 1?

The Witness: That's all right, I'll agree that that was arrived at for that particular thing.

Mr. March: When you say "that particular thing," you mean Potter County 1?

The Witness: That's right, in arriving at a production per acre pound for that alone.

Mr. March: That's right, none of the rest.

The Witness: No, we simply utilized the others to arrive at that figure.

By Mr. Keffer:

Q. All right, then when you came down to computing Moore County, Quadrant 2, you used Potter County 1 again, didn't you?

A. Yes.

Q. And that time your overall average figure was 36.82, wasn't it?

A. You are talking about Potter 2 or Moore 2?

Q. I am talking about Moore 2.

A. 36.88, that's right.

Q. 36.82; then you utilized Potter County 1 again in figuring Carson County, Quadrant 4, didn't you?

A. Yes.

Q. And that time you got an overall weighted figure of 81.43, didn't you?

A. That's right.

Q. And when you came down to figuring Hutchinson County 3, you used Potter County 1 again, didn't you?

A. That's right.

Q. By that time you had an overall figure of 45.94, didn't you?

A. That's right.

Q. Now, in the various calculations made from time to time and in which Potter County 1 figure was utilized, the figure has varied from 36.82 to 44.95?

A. Not at all.

Q. The figures that you utilized in these various computations?

A. That isn't a fact at all.

Q. What is the correct assumption?

A. Well, I have explained dozens of times and I will do it again—

Q. We don't want to go into it again.

Mr. March: Let him go ahead. It might be helpful.

By Mr. Keffer:

Q. He can go ahead if he wants to. I don't want to burden him with too many things.

A. As I have stated on previous occasions, we used the principle of taki.. ; any given quadrant on which we wanted to determine the production per acre pound and we used the adjacent quadrants to that. In other words, the summation of the data is what it amounts to for the entire area, and then from that determined a production per acre pound for the quadrant in question. Then we applied that to the weighted average pressure as of 1939.

All right, if we move over, we'll say from Quadrant 2, Moore County, to Quadrant 1, Moore County, we didn't utilize Hartley, Quadrant 4 or Quadrant 3, Potter, for the reason that they weren't adjacent to it. Then we took the areas immediately adjacent to Quadrant 1, Moore, and arrived at a production per acre pound for that area; then if we moved over here to Quadrant 3, Potter, we utilized the areas adjacent to that and arrived at a production per acre pound for that, in Quadrant 3.

Similarly we did that throughout the entire area. Now, it is obvious that in arriving at a figure to apply to a given area where you used different areas and different production, you are bound to have a different production per acre pound. Now, that's the whole story.

Q. I understood that perfectly, Mr. Hammer.

Now, Mr. Hammer, just one more time, and try to follow me, please, on this and let's don't spend all afternoon on it.

Now, when you got your figure in Potter 1, which is a figure that you assigned to it which you state is the correct figure of 58.97, now, that figure was an average of that quadrant with surrounding quadrants, wasn't it?

A. That's right.

Q. That's right. All right. When you came down to figure Moore County 1 you again got an average of surrounding quadrants, didn't you?

A. That's right.

Q. Which includes Potter County 1?

A. That's right.

Q. The average at that time was 37.88?

A. It included the original data.

Q. Well, I know it included the original data.

A. Before any production per acre pound had been calculated.

Q. But every time you get a different grouping you get a different average for the quadrants within the group which necessarily assigns to the quadrant we are speaking of a different value each time you make a different calculation?

A. Let's see, repeat that.

(The question referred to was read by the reporter, as set forth above.)

The Witness: Well, that is because you take in different areas each time.

By Mr. Keffer:

Q. Granted.

A. Certainly you do.

Q. But you get a different figure?

A. You get a different figure because you have different data to work on.

Q. And the original figure which you take is the correct one is also determined by averaging in others?

A. The summation, yes, of all of the quadrants around a given quadrant and the quadrant itself.

Q. Now, Mr. Hammer, can you go this far with me on

production. The best production in the Panhandle field is generally found through the axis portion.

A. Well, there are some qualifications to that.

Q. Generally that would be true?

A. Generally I would say that would be true.

Q. How did you figure out your quadrants?

A. Well, we attempted to lay them out so they would give as fair a representation as possible of all of the factors considered in the area in which we were interested.

Q. You say "we laid them out." Whom do you mean by "we"?

A. My boys were working under my direction.

Q. Who were the boys that were working under your direction?

A. I have had eight at different times, but the final decision was up to me.

Q. I know, but did all of you get together and work the thing out and determine where each quadrant was going to be?

A. I wouldn't say that, but we discussed it at different times.

A. You actually put them on, is that right?

A. Physically, no. I outlined them.

Q. What were the determining factors in placing the quadrants on your map?

A. Well, trying in the first place—there were two determining factors.

Q. All right, name them.

A. The original maps were on a scale of 4,000 feet to the inch. If my remembrance is right this is a reduction of one-fourth. We laid those quadrants out so that the arm of the planimeter we were using would cover an area without moving the instrument.

In addition to that we tried to so fit those areas that it would take into consideration as near as we could use what appeared to be the factors that would more nearly represent the area as to drainage, either to or from a given area.

Q. All right, on your Moore County Quadrant 1, you just missed that a long ways from the drainage standpoint, didn't you?

A. No, I don't think so.

Q. Well, look at your isobar lines.

A. As far as any effective drainage in Moore County—

Q. Oh, I am talking about the field as a whole. You have got your quadrants all over the field.

A. All right, I think it is fairly representative for the reason that there has existed up here in Moore 6 prior to 1937 a low pressure area in that district.

Q. All right, let's take Carson County 3, Quadrant 3, you missed it on that one, didn't you?

A. What?

Q. You missed the drainage question on that one, didn't you, Carson County 3?

A. No, I don't think so.

Q. You don't.

A. No.

Q. Do you think there is no drainage out of that quadrant?

A. I said this morning only a very very minor amount.

Q. I don't care—

A. There is some there, yes.

Q. Probably some—don't you know that there is a lot?

A. I don't know that it can be measured.

Q. All right, I'll say, could you have made a worse choice possibly than that one as shown by your isobar lines if you were trying to limit it to areas that reduced drainage in or out to a minimum?

A. Could I have done what?

Q. Could you have missed it more any place in the field that you did right there?

A. I think that is perhaps the best that could be done under existing conditions.

Q. When you drop down like that, taking just about the south half of it and leave out that northern line where your lines are going down so rapidly?

A. Well, that wouldn't have made any particular difference.

Q. All right, now, just be frank with me, Mr. Hammer. When it gets down to it, your quadrants were put on there as a matter of convenience and that's all.

A. Not necessarily.

Q. The only thing you have given—you have ignored drainage completely?

A. No, I haven't.

Q. Well, why should you draw the Carson County Quadrant 2—3, rather, as you did, if you are keeping the drainage question in mind?

A. Well, because the only effective point where the configuration of the isobars indicated drainage to the north.

Q. Well, it is drainage regardless of which way it goes?

A. Let me finish.

Q. All right.

A. Was that area in Carson adjoining an area to the north in Hutchinson where conditions were similar.

Q. All right. The north part of this block is similar to the conditions in Hutchinson County, isn't it, yet how about the south part of it?

A. Well, that isn't—

Q. It is all in the quadrant.

A. I know, but in making the determination, that isn't important at all.

Q. But you said the matter of drainage is important. You said that was one of your predominant motives.

A. I didn't say that it was one of my predominant motives. I said it was one of the factors taken into consideration.

Q. You took that and the matter of convenience in running your planimeter around. I cross examined you on that. I took it at face value. I want to know how much consideration you have given the drainage, that's all.

A. As a matter of fact, we didn't give an awful lot of consideration to drainage farther than it affected the grouping of these quadrants to arrive at it.

Q. Precisely, you gave your consideration to it when you made your computation, as you stated a number of times.

A. It was all balanced in.

Q. You gave little, if any, consideration to the drainage problem when you were seeking where the quadrants were going to be and where the boundary lines were going to be?

A. We gave it consideration.

Q. You just thought about it, is that the consideration you gave it?

A. Well, you must remember this, or anybody must, that this map here is a composite of a lot of larger maps, and we worked the thing out the best we could for the counties and then joined them together and we found out when we did that that they tied up nicely along the county line.

Q. All right, let's come over to Quadrant 2 in Carson County. You didn't pay much attention to drainage there, either, did you, as shown by your isobar lines?

A. Well, when we got that far away we didn't—

Q. I am talking about the field. Forget about Canadian River.

A. When we got that far away the only consideration just as I stated before was the balancing of that as against the other.

Q. When you got that far away from what?

A. From the position where Canadian River has acreage.

Q. Forget about that. When you selected these quadrants all over the field, you covered one end of the field to the other. We are talking about the field with reference to your selection of quadrants.

A. Well, and when we came to the point of arriving at a production per acre pound those were balanced in.

Q. I am not asking you that, Mr. Hammer. My point is, you didn't—you gave very little, if any, consideration to drainage in determining where those quadrants would be on your map?

A. That is true. We weren't making a drainage study. We were only making a study for reserves.

Q. You could have said that right at the start and saved a lot of questions. I think that's enough on that.

One other thing I almost forgot here. In balacing your quadrants, as you go down the structure, and especially in the western part of the structure, you necessarily include those quadrants along the center in more computations than you do the computations out on the edge, don't you? You use them more times?

A No, I don't think so.

Q. All right, let's just figure them out and see if you

don't. They are contiguous to more quadrants, aren't they?

The Trial Examiner: Perhaps, Mr. Keffer, you might save a little time if you would specifically designate the quadrants that you have reference to.

Mr. Keffer: Well, I didn't have reference to any particular one. We'll take Moore County 1, as an example.

Q. How many times have you used that one?
A. Moore 1?
Q. Yes, in your various computations.
A. If I have counted correctly, five times.
Q. Five—is that all?
A. That's right.
Q. All right, how many times did you use Hutchinson County 3?

The Trial Examiner: Mr. Keffer, was the first one Moore 2?

Mr. Keffer: Moore 1, Moore 2, Quadrant 2.

The Trial Examiner: Did you give your answer for Moore 2? Was that five—does that apply to Moore 2?

The Witness: Yes, I think so.

Mr. Keffer: Oh, the first one I asked him was 1. The one we are working on now is 2. I beg your pardon, Mr. Examiner, I misunderstood you.

The Witness: If I understood you correctly, you asked for Hartley 3.

By Mr. Keffer:

Q. Oh, there isn't any Hartley 3.
A. I mean Hutchinson 3.
Q. I did, yes. I asked you for Moore 1, Moore 2—
A. No, you started—
Q. Maybe—I believe you're right about that—sure as the world, I think you are. I'll be corrected on that.

Now, let's count them. I think we can count them right here on the map. You used Moore County 1 when you were figuring its own value you assigned to it, didn't you?

A. I used the original data, yes.

Q. That's one time.

A. Yes.

Q. Then you used in figuring Potter County 1, you used it, didn't you?

A. Now, we are talking about Hutchinson 3?

Q. No, we are talking about Moore 1, how often you used it.

A. Yes.

Q. You used it on Potter County 1. That's two, isn't it?

A. That's right.

Q. You used it on Potter County 2, that's three, isn't it?

A. That's right.

Q. You used it on Moore County 2, that's four, isn't it?

A. That's right.

Q. You used it on Moore County 6, that's five, isn't it?

A. I didn't calculate it on this down here—oh, in arriving at Moore County?

Q. Your field reserves.

A. Yes.

Q. What do we have there—six or five?

The Trial Examiner: Six.

By Mr. Keffer:

Q. You used it again over here when you were figuring Hutchinson County 3, didn't you?

A. Yes, that's right.

Q. That makes seven, and you had two others. You would have to check to be sure—Hutchinson 4 and Moore County 5. I don't know whether you used either one of those or not, but we do have seven definitely.

Mr. Spencer: They used Carson 4, they say, so that would make eight.

By Mr. Keffer:

Q. Now, does that appear to be right to you, Mr. Hammer?

Mr. March: I'll tell you, Mr. Keffer, I think you slipped up one. We can have him make a check on that during the recess and bring in what it is exactly on all of them. These gentlemen here said you slipped up one.

Mr. Keffer: I tried to count them.

Mr. March: We can check those.

Mr. Keffer: In fact, it doesn't make so much difference over here. It runs in practically—

Mr. March: We can have the witness check—

The Trial Examiner: Mr. Keffer, perhaps if you will specifically designate the quadrant that you desire that information on—

Mr. Keffer: Moore County 1, Moore County 2 and Hutchinson County 3. I think that would be enough to illustrate the point.

The Trial Examiner: Those are the quadrants that you desire, Mr. Keffer?

Mr. Keffer: Yes. It will be a very small matter to compute it.

The Witness: It would.

The Trial Examiner: He wants it for those three.

Mr. Keffer: I want it to illustrate and to show particularly what it is in the west part of the field.

The Witness: Did someone make a note of that? I didn't get those written down.

By Mr. Keffer:

Q. That was Moore 2, Moore 1 and Hutchinson 3.

You might take one other—take Hartley County, also, and one more, Wheeler County 1, also.

A. Are we going to have a five-minute recess here?

Mr. Keffer: I am not going to add any more here. Take Wheeler County 1. I would like to see what it shows.

The Witness: I am not sure that I have here the information on Wheeler County.

Mr. Keffer: Just give us what information you have on it, Mr. Hammer, and that will be all right.

The Witness: It will be entirely from memory because if it needs to be exact I would want to check it.

Mr. Keffer: That's all right. We might have a recess at this time.

The Trial Examiner: Very well, we will stand in recess for five minutes.

(At this point a short recess was taken, after which proceedings were resumed as follows:)

The Trial Examiner: The hearing will be in order.

By Mr. Keffer:

Q. Have you computed the use of the various quadrants referred to and the respective various computations, Mr. Hammer?

A. Yes, I have rechecked them. I will just read them and give them to you.

Q. That will be perfectly all right.

A. I used Moore County Quadrant 1, six times; used Moore County quadrant 2, seven times; used Hartley County Quadrant three times; used Hutchinson Quadrant 3, four times.

Q. Well, now, you are just including Canadian River's computations there?

A. That is what I utilized in my exhibit.

Q. I know, but I was asking for the field as a whole, Mr. Hammer.

A. That wasn't my understanding at all.

Mr. Spencer: That is the last thing we said.

Mr. Keffer: I intended certainly to make that very clear.

The Witness: I understood his last statement was that he wouldn't ask me for anything but Wheeler 1.

Mr. March: That was what it was. I remembed it distinctly. We will be glad to figure this out for you, but in the five-minute recess we had he was unable to define any more. We will compute the others after the recess this afternoon.

By Mr. Keffer:

Q. You used Moore County 2, seven times, as you gave it there?

A. That is true.

Q. You used it again in figuring Quadrant 5, Moore County, didn't you?

A. I presume so but I would have to check it.

Q. It is just broadside against it. I think you would be safe in saying that.

A. I would say that was right.

Q. I think on your basis you used it in computing Moore County 4, didn't you?

A. You are talking about Moore 2?

Q. Yes, you used Moore 2 when you computed Moore County Quadrant 4?

A. I believe so, but that—

Q. Of course, your isobaric lines would indicate a drain from Quadrant 4 to Quadrant 2?

A. I believe that is true.

Q. That would make Moore County 2, nine times. You can check that, if that is not correct, and correct it. That would make it nine times, wouldn't it, as we have discussed it?

Come over to Hutchinson County Quadrant 3, you would have used it again in computing Moore County 6, wouldn't you?

A. I believe we did.

Q. And in computing Hutchinson County Quadrant 5?

A. No, Quadrant 4.

Q. Oh, I see. Quadrant 4?

A. That is right.

Q. That would be two more times, Hutchinson County 2?

A. I imagine it would be.

Q. That would be three more times?

A. That is right.

Q. And possibly Carson County 3—you will probably want to check on that.

A. I would want to check on that.

Q. Anyway, that would make Hutchinson County 3, seven times and possibly eight times, is that correct? You can check it tonight.

A. I would want to check it.

Q. Now, you have used those quadrants along your axis more than you have the quadrants out on the edges on either side in the west part of the field, haven't you?

A. Well, before I would want to answer that I would want to check the rest of these quadrants. We have just picked out a few here.

Q. All right, you might check them on either side and see what the difference is, if any.

A. I wouldn't want to make a definite statement until I could check them.

Q. It stands to reason where you have a quadrant that is entirely surrounded you necessarily use it more times than a quadrant out on th edge of the field and where you just have quadrants on three sides of it. That would almost certainly follow, wouldn't it?

A. I imagine that is true. I would want to check it.

Q. All right, you check that and tell us if that isn't absolutely true. You can do it without much difficulty, can't you?

A. I can do that tonight.

Q. Now, Mr. Hammer, we had something about Wheeler County 1. What was your information on that?

A. Well, on Wheeler County 1 our information was that—well, in 1939 there were really no gas wells in Quadrant 1, Wheeler, and apparently the past history was such that the operators, outside of a couple of little oil pools that were in there, hadn't thought enough of the territory to drill it for gas, so we didn't consider Wheeler County Quadrant 1 as really being commercial gas territory.

Q. Well, then, how did you figure the reserves in it?

A. We didn't give it any reserve.

Q. None at all?

A. No.

Q. You just figured it out?

A. Threw it out.

Q. You didn't figure it in with any other reserves?

A. I don't believe so, no.

Q. Now, how many wells did you say were in that?

A. In Quadrant 1?

Q. Quadrant 1 of Wheeler County.

A. My remembrance—you are talking about gas wells?

Q. Gas wells, that is right.

A. I don't recall offhand but I think there were no gas wells that were hooked up. My remembrance is that there weren't in that area to exceed two wells that were even

considered as gas wells and they were very small wells quite a long distance from the pipe lines, and it was my opinion that that area over there in Quadrant 1 of Wheeler County really shouldn't be considered as productive territory.

Q. You did have some oil wells in there that had produced some substantial volumes of gas, hadn't you?

A. Well, it probably had, but the oil wells themselves didn't amount to very much. As compared to the rest of the field, they were small wells.

Q. Had there been much pressure decline in that area?

A. Well, around those pools, as nearly as we could get the information, there was considerable decline. I would say this, that of all the area in the entire field there was less data upon which to base anything in Quadrant 1, Wheeler County, than in any of the rest of them.

Q. Then the upshot of it is, whatever it might be worth, there are some areas in the field even today where you don't feel justified in applying pressure decline methods?

A. Or any other method.

Q. Why didn't you try the sand thickness porosity method on that for a little diversion to see how you came out?

A. I didn't have any time to waste.

Q. Are there any more quadrants like that in the field?

A. Well, there are some that approach close to it.

Q. What are they?

A. I would have to do a little checking on that.

The Trial Examiner: Do you mean, Mr. Keffer, Quadrants which he had disregarded or had similar characteristics?

Mr. Keffer: That had similar characteristics to Wheeler County 1. He might not have disregarded them but as a matter of fact, I don't think he did.

The Witness: I may have some notes on that. Does someone have available that exhibit that we put in on the reserves for the entire field?

Mr. Lange: Yes.

The Witness (Examining document): Wheeler 1 on Exhibit 186, on that you will notice it was assigned no reserve

at all. You will also notice on the same exhibit 186 that Wheeler Quadrant 5—

By Mr. Keffer:

Q. Which one?

A. Wheeler 5.

Q. Wheeler 5?

A. Yes. We could only give that a remaining reserve per acre of about 2,921 Mcf., which is very small for productive territory.

Q. Is that per acre or for the Quadrant?

A. No, that is 2,121 Mcf. per acre. Of course, what I am talking about are the figures on remaining gas reserves per acre. Actually you will notice that the highest assigned to any of the quadrants in Wheeler County is 6,980 Mcf. per acre.

Q. Remaining reserve?

A. That is right.

Q. Down to the 25-pound abandonment pressure?

A. That is right. That shows that there are some areas there, particularly Wheeler 5, that if you had to drill them today you probably wouldn't drill them because of the small amount of gas per acre.

Q. Take Wheeler County 5, what is the pressure on that, Mr. Hammer?

A. You mean the weight of the pressure?

Q. Yes.

A. Well, I don't know that I have that with me. I really don't believe I have, Mr. Keffer.

Q. Well, you can tell by looking at the map it is very, very low, can't you?

A. I think that is right.

Q. Do you know how low it is?

A. I wouldn't want to say until I checked it.

Q. Sir?

A. I wouldn't want to say until I checked it.

Q. Let's look at the map, Exhibit 179. I think it will indicate that.

A. It will show the isobars.

Q. Wheeler County 5 starts with the pressure on the south side, having a pressure of about 200 pounds?

A. That is correct.

Q. Then it varies from about 90 to 200 pounds.

A. Yes, from 200 at the high to about 90 for the low.

Q. Are there any other quadrants in the field you find in about that situation, Mr. Hammer?

A. No, in general I wouldn't say there is.

Q. How about the quadrants over in Gray County, Quadrant 2?

A. Well, that appears to be, although the pressure is relatively high there, this has been assigned to a low amount of gas per acre.

Q. A what?

A. A low amount of gas per acre.

Q. You show better than 8,000,000 feet per acre remaining?

A. Yes.

Q. That is down to 25?

A. Yes.

Q. Isn't that a pretty substantial volume of gas?

A. It might be under certain conditions.

Q. Has there been any production much from that quadrant?

A. No.

Q. No production from them?

A. There has been—their production has been very small.

Q. How did you get your estimate on it? Did you use the porosity sand thickness method on that one?

A. No.

Q. Tell us how you did it?

A. Well, by balancing or grouping—I am talking from memory because I don't have these groupings here.

Q. I understand.

A. My remembrance is that we used Quadrant 1 and Quadrant 4 in Gray County, Quadrant 5, Gray County, and Quadrant 4, Gray County. In other words, we grouped this area right across here south of the structural depression.

Q. I am not sure that I understand you. Rather than use the porosity sand thickness method you threw that in with another quadrant, didn't you, and considered it all as one quadrant? Didn't you throw that in with Quadrant

5 of Gray County and ignore your boundary lines between quadrants?

A. No.

Q. You didn't do that?

A. No. I feel quite sure—as I said, I would want to check that.

Q. In weighting that number 5 down there with the others when you had no production, how did you reach out and get a weighting figure, a figure you used in your weighting process?

A. Well, there was production on both sides of it, both to the east and to the west.

Q. You took the production in other quadrants and determined that that ought to be the production in Quadrant 2, Gray County, is that right?

A. Well, we assigned—

Q. Sir?

A. We grouped that just as we have grouped the others except that we couldn't group anything to the north of it, so that is my remembrance, we grouped it to the east and west of it.

Q. We may be talking about the same thing, Mr. Hammer, but the whole point is that on Quadrant 2 in Gray County you didn't have enough data to figure it by itself?

A. That is true.

Q. Now, in order to get enough data to figure it you had to go out and throw it in with some others and get an average figure, an average of what they all showed, and bring it back and assume that would be the figure on that before you started your averaging process, is that correct?

A. I don't think you could say we assumed anything. We simply took both areas and used the same process there.

Q. But in these county quadrants we have been talking about, except Wheeler 1, you had basic data you could utilize in each of the quadrants, and now you come down to Quadrant 2 in Gray County and you don't have that basic data. From what source did you get it?

A. I said that my remembrance is we took the data from Quadrant 1 and 4—no, Quadrant 1 and 6 in Gray County and Quadrant 4 in Gray County.

Q. All right. Now let me restate it.

You took what value you had in Quadrant 4, Gray County; Quadrant 1, Gray County; Quadrant 6, Gray County, and averaged that up, is that right?

A. Yes, we utilized those entire areas. That is my remembrance.

Q. Then you took that figure, whatever it was, that average figure, and arbitrarily applied it to Quadrant 2 to supply the missing data?

A. That is right.

Q. I thought we understood each other.

Now, as a matter of fact, Mr. Hammer when its gets right down to it you could have missed on your pressure decline quite a little, couldn't you?

A. Well, the data aren't as good as they are elsewhere.

Q. That is right, and you have already said with the pressure decline to be really good you have to have data behind it.

A. Yes, that is right.

Q. And the more data you have the better it is?

A. That is right.

Q. Now you have answered, I believe, or have shown us the acre content of that quadrant, that is, the remaining pressure to the 25 lb. abandonment, and I presume since there has been that little production the original reserves would be very similar to the remaining reserves?

A. No. Regardless of how small a permeability you might have, there would be bound to be some movement to nearby wells. In other words, I can't illustrate an area entirely because you don't know the extent—in other words, there hasn't been enough development in there to give you sufficient data.

Q. There hasn't been enough to get even the rock pressure there?

A. No.

Q. I mean the sand thickness porosity there.

A. No.

Q. So you are both about in the same boat from that viewpoint?

A. I think so.

Q. Now, to get over in Gray County, quadrant—just

south of that high spot in Gray County Quadrant 5, I guess it is—

A. That is the one we have been talking about?

Q. Sir?

A. Isn't that the one we have been talking about?

Q. Just a minute.

We were talking about the same quadrant after all?

A. Yes.

Q. Now let's go to Quadrant 5. What is your treatment of Quadrant 5, Gray County?

A. In general it is the same treatment for that as in the quadrant we had been talking about previously.

Q. Now, I believe you stated you had sufficient interest in that area which would be Quadrants 5 and 2, Gray County, being the area just south of the Gray County faulting, which we referred to earlier this afternoon, to make a much closer check on that than you did on other parts of the field, is that corerct?

A. In general as to the wells, I would say that was true.

Q. What did they show in there as to the number of wells and the size of them, Mr. Hammer?

A. I don't have that data with me but from memory it showed the wells were of very small potential.

Q. Yes, I believe you stated that earlier, didn't you?

A. Yes.

Q. Did it show a number of dry holes in there?

A. I would have to check that, Mr. Keffer.

Q. Do you have data with you whereby you can check the dry holes on that area?

A. I doubt it. I don't know whether I could or not.

Q. What attention do you pay to a dry hole in applying the pressure decline method?

A. Sir?

Mr. Keffer: Read the question, Mr. Reporter.

(The question referred to was read by the reporter as set forth above.)

The Witness: Well, a dry hole automatically indicates that immediately around the hole there isn't any—in other words, it is so tight, to use the oil field expression, that gas can't get into the part of the formation penetrated by the bit.

By Mr. Keffer:

Q. Suppose you found a good many of them in Quadrant 5, particularly in Gray County, and some of them in Quadrant 2, what would that indicate to you?

A. Well, under reservoir conditions as they seem to be and the character—I will put it another way. The character of the producing formation in the Texas Panhandle would be—I think I can best illustrate that, Mr. Keffer, the point I am trying to make, by telling of an occurrence that happened to me elsewhere.

Q. All right, go ahead.

A. We were drilling a hole for the Northern Pacific Railway Company in the state of Montana and a bunch of school teachers came out to—

Q. To tell you how to do it?

A. —to see this drilling rig. They said to the driller, a man by the name of George Waldrip, "How much territory will this hole condemn down there when you hit that sand at about 4500 feet?"

Without hesitation he said, "Madam, six inches, four thousand feet underground."

That is the point I wanted to bring out here.

Q. I get your point exactly.

Let's apply it both ways, Mr. Hammer. Coming back to the leases you were talking about so much this morning and which you held down to about 640 acres, why didn't you hold them down to about six inches there each way around the hole? They were tight spots and we agreed on that.

A. Well, you are coming to the question of the variables of permeability.

Q. But if a dry hole in a tight spot over here condemns practically nothing, then a small well in a tight spot over in the west part of the field which creates a higher pressure area there which you referred to would mean nothing or little, wouldn't it?

A. No, I wouldn't agree to that.

Q. All right.

A. Because—

Q. That is all right.

Now coming back here to Gray County again, figuring

your acreage in there, you ran your isobaric lines as you showed them there and figured in dry holes?

A. I took the entire area.

Q. You didn't count anything out for the dry holes on the theory you figured six inches was all that was condemned anyway?

A. That is right.

Q. That would give you possibly an exaggerated figure down there of acre content in that area?

A. Well, I think that is a good point there to illustrate. If you utilize an area like that with other areas you automatically, because you do use it, create a lower reserve in another area.

Q. Why do you?

A. Well, because you are taking into account bigger acreage for the same amount of gas that has come out.

Q. You figured those areas right close to eight million feet, two of them, I expect, per acre, so that is a pretty high figure to start with for dry holes?

A. What two are you talking about?

Q. Quadrant 2 and 5, Gray County.

A. Well, the point there—You mean just those two?

Q. Sir?

A. You mean just those two?

Q. Yes.

A. Well, it is possible that—I will put it this way, if I may answer the question in my own manner.

Q. All right, go ahead.

A. Under present conditions of supply in that territory it might not be economical to drill or try to produce from that area, but there may come a time when economic conditions change and when it would be profitable to operate in that territory.

Q. I take it you mean by that when you get a great deal more for your gas than you can get today?

A. That time will eventually come. It has every other place.

Q. In other words, though you are not producing much gas you are getting more per thousand *cubic* feet, for example, and maybe the time will come sometime in the distant future when somebody will drill it?

A. I think that if that area there, for example, were in the Appalachian field they would be drilling wells in it.

Q. I wonder if we could move it over there? Do you know any way we could do it? I wonder if we could drill our wells over there instead of in Gray County?

A. I think that is it.

Mr. March: Another one of your affiliates are doing that, Mr. Keffer.

Mr. Keffer: I don't understand that, Mr. March.

Mr. March: I think another one of your affiliates are doing that.

Mr. Keffer: All right.

Mr. Spencer: I didn't know Mr. Keffer had any affiliates. I am glad to know that.

Mr. Keffer: That is right. I have a wife and daughter. I guess they are affiliated.

Mr. March: I was speaking professionally.

Mr. Keffer: All right.

I have one further question along that line, Mr. Hammer.

Q. The area we have been speaking of, Quadrants 2 and 5, particularly, in Gray County, hold pretty well true to the conditions you found there in the southern portion of Quadrant 4, Gray County? You didn't find much deviation there, did you?

A. Well, I wouldn't say that would be a true statement of the situation.

Q. I will qualify it to the degree you think it ought to be qualified.

A. I would say that the southwestern part of Quadrant 4 and the northwestern part of Quadrant 3 in Gray County would probably be better territory than that to the east.

Q. Very much better?

A. It is better.

Q. Can you find any connected well in that area?

A. Yes, there has been some production out of that territory.

Q. Did you find any dry holes in that area?

A. I believe that there were one or two that I remember.

Q. Well, did you find the wells in that area were generally small, this additional area you described or referred to?

A. You mean the area to the east?

Q. Yes. Were these generally small wells?

A. I think in general that is true, that is, along the extreme edge at that particular point.

Q. What is the pressure generally prevailing in that area as shown by your isobar map, Exhibit 179?

A. Which area, Mr. Keffer?

Q. In areas designated by Quadrants 2 and 5, Gray County, and 3, and the south part of Quadrant 4 in Gray County.

A. There is one well just south of this depressed area here situated in Quadrant 5, Gray County, that was reported by the Texas Railroad Commission to have a pressure of 435 pounds in 1939.

Q. In Quadrant 4 the pressure in the south part would be from 380 pounds upwards, would it not?

A. No, because in the southeastern part of Quadrant 4, Gray County, with the northeast Quadrant part of Quadrant 3, the pressures there got down to 360 pounds—

Q. That is the result of one well, isn't it?

A. No, I think there are two wells there.

Q. Two wells pulled it down but otherwise the pressures will run from 380 pounds up to virgin rock pressure, or near that, to 430 pounds, is that correct?

A. The Texas Railroad Commission in 1939 reported the pressure there at 435 pounds.

Q. 435 pounds?

A. Yes.

Q. That would be true of the wells in Quadrant 2, Gray County, and Quadrant 5, Gray County?

A. That is right.

Q. And in Quadrant 3, Gray County, except for that area of two wells that you spoke of, is that correct? In fact, this Quadrant 3, except for that area, consists of wells 400 pounds and above? I mean except the isolated area of the two wells which you referred to.

A. Yes, that is right.

Q. So the area prevailing in there is much higher—I mean, the pressure in that area is much higher than the general average pressure of the field?

A. Yes, that is true.

Q. Now, Mr. Hammer, in applying your pressure decline method—strike that.

You made a statement that it might take a million years for the field to equalize?

A. I think I made such a statement.

Q. How did you figure that out? How did you calculate it?

A. It was just an expression.

Q. As a matter of fact, it has only taken about fifteen years at the outset for it to get in this shape, hasn't it?

A. That is quite a different problem, Mr. Keffer. The thing that put—

Q. Just answer my question. It has only taken it about fifteen years to get in this shape, hasn't it?

A. That is right.

Q. Then gas will continue to flow as it has in the past and if it ate its way back to this position in fifteen years, isn't it reasonable to assume that something like that time or not much longer would cause it to equalize if those wells were shut in?

A. No, I don't think so. You see you are overlooking, Mr. Keffer, the fact that the thing that produced that low pressure area was gas that came out of the ground, vertically against—or, rather, vertically through conduits that had no *resistence* as far as permeability was concerned. That is quite a different problem from—

Q. What conduits are you talking about?

A. The tubing and the casing.

Q. I surely agree with you, but that is where you get into that six inch situation again?

A. Yes, but those casings come vertically out of the ground to the surface.

Q. Yes, I understand that, but how does that gas get to the casing in order to come out? What must it do first?

A. It has to have a pressure differential, of course.

Q. What does it come through to get to that casing?

A. The producing formation.

Q. The producing formation?

A. Yes.

Q. What does it go through when it is going to equalize across there?

Mr. March: You are presuming—

Mr. Keffer: I am not presuming a thing on earth, Mr. March. Mr. Hammer has testified it would equalize.

Mr. March: But he hasn't testified in equalization it would all run to the Borger area. It would be a hot spot in Borger if it all went over there.

Mr. Keffer: Go ahead and answer the question.

The Witness: Please read the question.

(The question referred to was read by the reporter as set forth above.)

Mr. Keffer: I will add "from the low pressures to the high pressure areas."

The Witness: Of course, it could only pass through the reservoir.

By Mr. Keffer:

Q. Every foot of gas that has ever been produced has passed through the reservoir at some distance or other to get to the well?

A. Certainly.

Q. If it didn't do that you would just produce the six inches that the casing uncovered?

A. Certainly.

Q. Now to go to these Panhandle Eastern Shamrock wells we talked about a little yesterday afternoon. We found there when a well was first drilled in that area that one-fourth of the pressure was gone, didn't we?

A. We found out the pressure had been reduced. I don't remember the exact amount.

Q. We figured out 109 pounds was the pressure in one case and it was a little over 100 pounds in another case, which would be more than a fourth, figuring down to your 25-pound abandonment pressure which you have figured. That pressure had lost 25 per cent of it in how long? How long did it take it to do that?

A. Well, that is a question that is largely—I don't believe it can be answered unless you knew the dates of all of the wells that had been drilled close to them and I don't know them.

Q. Let's assume they were drilled within the past two or three years, what would your answer be then?

A. They haven't been drilled within the last two or three years.

Q. How do you know that?

A. I know that in that area there within two or three miles of where those wells are that there hasn't been any wells drilled because they were drilled in 1939.

Q. 1939?

A. Yes.

Q. That has been less than a year?

A. Yes, since they were drilled.

Q. Did it lose that 25 per cent in a year's time across that two or three miles?

A. No, they—what time are you talking about—between when they were drilled and now?

Q. Yes.

A. I don't have any pressure as of this date.

Q. Do you know when the wells were drilled—the last wells are what we are talking about. They were drilled in an area which had lost through drainage, we will say, roughly 25 per cent of the gas then?

A. Yes, they had lost some gas.

Q. My point is, how long did it take that particular area to lose that 25 per cent of the gas?

A. Well, you tell me when this area up in the east part of Quadrant 6, Moore County, developed, and I can give you an answer.

Q. I will give you that in just a moment. However, before I give you that, let me remind you that you had all that drainage down to the south and the southeast, and not up to that spot at all.

A. When?

Q. Yesterday afternoon when we were discussing those wells.

A. Oh, no.

Q. I asked you where the gas went and you figured out a well down here in the Charles Ragsdale Survey as to where the gas would drain in the area where those wells were drilled.

A. I don't think the record shows that. I said "locally." I am talking about the local load down there.

Q. You tried to leave the impression, or you did leave the impression with me, that the drainage was caused locally by those wells inasmuch as they were nearest to the southeast.

A. The point is that this area here in Quadrant 6, Moore

County—I don't recall the exact date—has been a low pressure area there for a number of years and the chances are that any gas from the area where these wells were drilled in 1939, there would be the lowest low pressure area and it would have the most direct effect upon it. That would be to the northeast.

Q. Why were you stating yesterday evening that the drainage was caused locally by the wells to the southeast?

A. Here is your low pressure area right in here between the high pressure area and another high pressure area at a higher pressure area down here (indicating), local low pressure area. Here is a low pressure area (indicating). Naturally you are going to get local drainage into the local low pressure area.

Q. You want to say now it is drained over to the Byrd-Armstrong pool in Quadrant 6?

A. I think that would have the greatest effect upon it.

Q. It is about six miles on an average?

A. No, it is about three miles.

Q. From where are you measuring to?

A. I am measuring from the high pressure area and from the high pressure wells. You can pick out any sections you want to down here and it will measure three miles.

Q. You took the high pressure wells. What I want to know is about those low pressure wells that had lost 25 per cent. It is altogether a different question. Those low pressure wells wouldn't drain across the high pressure well you measured in between and the low spot around the Byrd-Armstrong pool, would they?

A. No.

Q. Then when you said they lost their gas from the southeast you really meant that, didn't you?

A. I want to qualify that, Mr. Keffer.

Q. All right, qualify it.

A. This is only one map out of the five that we made. I would have to recall some way what the previous year's configuration showed.

Q. Do you have those other maps so that we can take a look at them?

A. They are in Washington, D. C.

Q. Does Mr. Roosevelt have them, or somebody up there?

A. They are all ready if somebody wants to look at them.

Q. Well, I won't go get them. The fact remains there has been drainage; let's agree on that.

A. We will agree on that.

* * * * *

Witness HAMMER further testified on cross examination, Vol. 57, pp. 7949-8107, inclusive, as follows:

The witness stated that the diverse conditions prevailing throughout the field and in particular areas in the field were not taken into account precisely in laying out his quadrants; that each quadrant contained various characteristics. There was a great variation in some of them in the producing ability of wells, particularly in Quadrant 2, Potter County. The variation was also great in Moore County Quadrant 2.

The witness also explained in this connection that a planimeter, which had influenced him in laying out the quadrants, was a device for measuring areas on a map and computing acre content.

The witness made no study of dry holes generally and did not remember whether Canadian's wells near the fault line were small or not. He just wasn't interested in the open flows of the wells at all. He stated that the southern and eastern sides of Wheeler County did not look good to him from a producing standpoint because the dolomite sections in those areas were not thick. He also stated that northern Hutchinson County was an area of low or slow open flows. He did not particularly remember the size of the wells in northern Gray County and Carson County along the limits of the field.

It didn't make any difference to him about the variation in open flows and other producing characteristics in his method of determination. This he says was all weighted out and eliminated by a process of grouping and averaging surrounding quadrants. He did this by starting from the west and going east, and says, he automatically took these things into consideration progressively.

For example, he took into account but four different quadrants in estimating the acre-content of the Hartley County Quadrant, but if these four quadrants had just been one area or one quadrant, then in order to determine the acre content he would have balanced this one large quadrant

with all adjoining quadrants. He would not have just taken the one large quadrant and figured the data on this quadrant alone because to have done so he would have eliminated other quadrants that would have a greater bearing on the matter. For example, Quadrant 3, Moore County, also Quadrant 2, Moore County; Quadrant 5, Moore County and Quadrant 2, Potter County, and if all of these quadrants were eliminated it would affect his result. Also, in figuring the Hartley County Quadrant as he did figure it, he gave no weight at all to the quadrants last mentioned.

A prior series of maps, prior to Exhibit 179, were taken into account in his reserve study, but these maps were not available for checking.

The witness further testified as follows (Vol. 57, pp. 7980-8016):

Q. Mr. Hammer, we were discussing quadrants generally in the western part of Moore County and the western part of Potter County, weren't we?

A. Yes.

Q. And I asked you if you could not have made your estimate just as well and gotten the same result in so far as Hartley County quadrant was concerned by considering only Potter County 3, Moore County 3, Moore County 4, and Hartley County all as one quadrant and one area.

A. And my answer was that this map doesn't represent what has happened over the five-year period that we utilized. This is a map for one year. There were changes some places.

Q. Well, obviously, you admit whether based upon this map or upon other maps that Moore County 4, Moore 3, Potter County Quadrant 3 all affected Hartley County quadrant, and as you say, you averaged them—that is not the word—

A. Grouped them.

Q. You grouped them?

A. Yes, that is true. I also stated that we had utilized it necessarily because it existed—a large area in Quadrant 3 and Quadrant 4, Moore County, which hasn't at any time indicated any drop in pressure. In other words, it is virtually virgin territory, but because we had utilized it, the resulting reserve was a minimum.

Q. I know you stated that. I believe it will be higher,

but we will argue that later. I think our position is clear in that respect.

Now, you just stated Quadrant 4 in Moore County; Quadrant 3 in Moore County, were virtually virgin pressures, I believe?

A. Part of them, that is right.

Q. Take them as a whole, they are all very high pressure areas?

A. Yes.

Q. And a great part of it is virgin pressure?

A. That is right.

Q. Are there any wells much in Quadrant 4 and Quadrant 3 in Moore County?

A. Well, there are a good many wells in Quadrant 3, Moore County.

Q. Where are they?

A. There is a well in Section 18, Block G & M Survey; there is another well in Section 22; there is a well in Section 23; there are two or three wells along the southern border in Block 019 in Quadrant 3.

Q. That makes about six wells?

A. So far. I am not through—

Q. Go ahead.

A. There are several wells along—

Q. Let's be specific. Let's don't say "several."

A. All right.

There is one well in Section 76. I think that is the EL & RR, Block P Mc Survey. There is another well in Section 73, G & M Block 2.

Q. Let's say that consists of two wells. Go ahead.

A. There is a well in Section 30—

Q. Let's check that well. It is very close to the edge, isn't it?

A. All right. There is another well in Section 22, EL & RR Survey, Block P MC. There is a well in Section 21 for the same survey—of the same survey. There is a well in Section 18 in the same survey; there is a well in Section 20 of the same survey.

Q. That would be seven of them.

A. There is a well in Section 14 of the same survey.

Q. Eight.

A. Mr. Keffer wants me to mention this dry hole in Section G & M Survey.

The Trial Examiner: As a well?

The Witness: He wanted me to and I told him it was a dry hole. I believe that is all except—I think those are all of the wells in there.

By Mr. Keffer:

Q. What about the next quadrant, Quadrant 4, Moore County?

A. That has little development.

I think it only has one well in the northwest corner in Section—

Q. Section 308, Block 44?

A. Section 308, Block 44.

Q. Now, Mr, Hammer, the one well in Quadrant 4, Moore County, which you referred to is in the very northeast section of the quadrant, isn't it?

A. Yes, that is right.

Q. Just as completely in the corner as it is possible for a well to be so far as the section is concerned?

A. It couldn't get much farther in the corner.

Q. All right. Now, of the eight producing wells you mentioned in Quadrant 3, two of them are right on the south line; that is, they are on Sections that really dip over a little into Quadrant 3, Potter County, aren't they?

A. They are right along the county line.

Q. That is right, right on the very south boundary line of your quadrant?

A. That is right.

Q. And the other six producing wells that you mentioned are right along in the southeast corner of the quadrant, aren't they?

A. In general they are in the southern part.

Q. That is right, and the farthest one away from your east quadrant line is about a mile and a half?

A. That is about right.

Q. There is an area, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20—no, I got down too far.

Well, we'll take this Quadrant 4 first. Quadrant 4 is ten miles long by 9 miles wide, that's 90 square miles, isn't it? Answer my question first.

A. Well, that's right, but a great part of it is outside Quadrant 4—is outside the limits of the field.

Q. That's right, I would say about half of it, roughly.

A. Well, my guess would be more than that.

Q. Well, if you started here with a straight line and came out over here (indicating), you would have about half.

A. Well, call it half.

Q. I think that would be a pretty close estimate, half of it.

We had 90 square miles, so we have got 45 square miles in there with one well, haven't we?

A. That's right.

Q. All right, now, we'll take this other quadrant, this Quadrant 3. It is about 9½ miles north and south and 9 miles east and west. Call it 9 miles square, that's 81 square miles, I believe, with eight producing wells.

A. All right.

Q. And those eight producing wells are all close to the south edge or the southeast line of the quadrant.

A. All right, that's true.

Q. And all of that is in the producing area as you have it outlined?

A. That's right.

Q. So you have there 81 square miles plus 45, that's 126 square miles, with 9 producing wells, all of them near the edge of the area, haven't you?

A. That is true, as far as you have gone, but—

Q. Yes, all right.

A. But you have left out of your consideration Potter Quadrant 3.

Q. I don't know whether I want to come to it or not, but I haven't come to it yet.

A. There are quite a number of wells down there.

Q. But the statement I have just made with respect to Quadrants 3 and 4, Moore County—

A. In general that is true.

Q. Now, don't you have far more wells per acre, far closer spacing of wells in Quadrant 5 and Quadrant 2 in Gray County than you have in Quadrant 3 and Quadrant 4, Moore County?

A. Read that question, please.

(The question referred to was read by the reporter as set forth above.)

By Mr. Keffer:

Q. Far more?

A. No, I would say there were fewer wells.

Q. Per acre, if you are considering the acres?

A. Fewer wells.

Q. Well, how many wells do you find in those two quadrants, including your dry holes?

A. Well, I find, as near as I can tell from the map, six wells. I can't say whether they are dry or not from the map.

Q. All right. Now, take the area that we have referred to, Quadrant 5, Gray County, and Quadrant 2, Gray County, limiting it to the confines of the field, taking your scale, don't you find at least twice as much area out here in Quadrant 3, Moore County, and Quadrant 4, Moore County, than you find in Quadrant 2 and Quadrant 5, Gray County, this area right in here (indicating) than in this area (indicating)?

A. Yes, the acreage is larger.

Q. So you really have more wells per acre, closer spacing of wells over in that quadrant—that is, Quadrant 5 and Quadrant 2, Gray County, than you have in Quadrant 3 and Quadrant 4, Moore County, haven't you?

A. Compared to acreage that is possibly true.

Q. Now, I think you will find more wells over there, Mr. Hammer. I am not assuming that you counted all the wells. It is hard to do it on this map. I appreciate that the scale is so small, but that is enough to illustrate the very thing that I have in mind.

I believe I asked you that the wells are better grouped over Quadrant 5 and Quadrant 2, Gray County, than they are over Quadrant 4 and Quadrant 3, Moore County?

A. You don't mean better grouped—

Q. I mean they cover the area—they are better distributed—that's the word.

A. Yes, that is true.

Q. That is correct. Now, if you didn't have enough data to figure Quadrant 5 and Quadrant 3, Gray County, which you said yesterday that you didn't have, and had to take the figures from some other counties to get that—some other quadrants to get that—then you didn't have enough out here to figure Quadrant 3 and Quadrant 4, Moore County?

A. That is an analogy that doesn't exist.

Q. Tell us why.

A. Over in the quadrant we are talking about in Moore County with the exception of that one dry hole, the Brown I believe you call it, there haven't been any wells, at least to my memory, to indicate that the development would not continue on to the west. In other words, you have over here in Hartley County a gas well. All right, now, you have a gas well over here and you have a series of gas wells over in Quadrant 2 and you have some gas wells in Quadrant 3, and you have gas wells in Quadrant 5, Moore County, and you have a gas well in Quadrant 8, Moore County. There isn't any reason to suppose but what this territory across here is not all productive territory.

Q. That may be very true, but that still doesn't answer my question. You have had that same situation over in Gray County, didn't you?

A. Well, but the point is that we have more reason to believe that conditions are similar in Moore County.

Q. No, I don't believe you understand my question. You had wells that were located pretty generally over Quadrant 2 and Quadrant 5, Gray County, enough to give you, I should say, a very good picture of those two quadrants.

A. None of those wells, as I stated, and as I think you agreed, had been connected up. They had not given out any production. The wells over in Moore County have.

Q. All right, but the wells have been giving up the production; they weren't in the area that you were estimating?

A. No, naturally; part of that area has not been drilled.

Q. Now, you take Quadrant 4 and Quadrant 3, great areas in which no wells have been drilled, and a great, major portion of that area which has not been drilled is 430 pounds virgin pressure, as you have figured it?

A. Yes.

Q. As you have figured it, and all of them are high. Now necessarily when you were averaging those quadrants in with Quadrant 5 and Quadrant 2, we'll say, Moore County, to get the production out there in Quadrant 4 and Quadrant 3, and your rock pressure was one of the most important things in that average, you have actually taken wells, very largely over in 5 and 2—Quadrants 5 and 2, and assigned to them the rock pressures on Quadrants 4 and 3 in your averaging and got a distorted figure, didn't you?

A. You have left out an equally important factor.

Q. All right, you name it.

A. That is the acreage involved.

Q. That is important. Now, you go ahead and answer it.

A. Well, now, by the very method—let's take for example one example and I think it will suffice.

Q. All right.

A. We have mentioned before and I will try to explain it again, if you take Quadrant 2, Moore County, and just assume that there is no production at all in Quadrant 3, and you make your determination on Quadrant 2 alone, then using the same production in Quadrant 2, if you then embrace all of the acreage in 3 and combine the two, the result will be a minimum result because you have taken in so much more acreage.

Q. There would be a minimum result per acre?

A. Minimum result per acre pound.

Q. Per acre, I'll grant you that.

A. Per acre pound.

Q. But doesn't necessarily result in the minimum per billion cubic feet in the area reserves?

A. Yes, it does.

Q. You tell us how.

A. If you get a minimum production per acre pound and you apply that to the acreage—

Q. I know, but you have got twice as many acres or maybe three times. That is the catch in the whole thing?

A. Well, the point is that—this whole thing is based on the production per acre pound. Now, if you get a production per acre pound—

Q. When you get a production per acre pound, in order to get the production for the area you would multiply it by the acres, wouldn't you?

A. Well, when you get the production per acre pound that is the first thing that is determined.

Q. Oh, of course, and then the next thing, you multiply it by the acres and the more acres you have got the more reserves you have got?

A. By acres and by pounds.

Q. You have already had your pounds.

A. And by the volume of gas. You have three factors.

Q. Well, no, the volume of gas is what is your answer. You don't assume what that is before you start your calculation. That is what you end up with.

A. No, but you determine first your production per acre pound.

Q. Surely.

A. All right, then, and assume that you would double your acreage, it would cut your production per acre pound decline in half.

Q. Of course, but still you would have twice as much acres in the reservoir because you double your acreage

A. Well, you would have a larger amount, that's true.

Q. All right. We had a big argument on that the other day and I think we finally settled it.

The Trial Examiner: We will take a short recess.

(At this point a short recess was taken, after which proceedings were resumed as follows:)

The Trial Examiner: The hearing will be in order.

By Mr. Keffer:

Q. Just another question or two, Mr. Hammer, on the things we were discussing, to gather up some loose ends.

You have originally your virgin pressure and comparatively little production in Quadrants 3 and 4, Moore County.

A. In general that is true,

Q. You have more production in Quadrant 5, Moore County, and Quadrant 2, Moore County, which is just to the west of 4 and 3.

A. Just to the east.

Q. I mean just to the east.

A. That is true.

Q. Now, it was necessary as a matter of fact—as a matter of fact, it just resulted, in the way you did it, that you take production pretty well, almost entirely, in Quadrant 5 and Quadrant 2 to determine your values in Quadrants 3 and 4?

A. Yes, they were grouped in, that is true.

Q. And the grouping resulted, since most of your production was in 5 and 2, most of your pressure drop was in 5 and 2, you evidently had to take—or in your adjusting,

you necessarily gave effect to those factors in 5 and 2, to determine your reserves in 3 and 4?

A. Yes, that is right.

Q. That's right. Now, in 3 and 4, if it should develop into a lean area—remember they are on the edges of the field there—although the pressures are relatively high, then you have got too high a figure for 3 and 4. That would follow, wouldn't it?

A. If they should develop to be lean, that is true, but we haven't any reason to suspect that they will.

Q. Did you examine the sand thickness on that—porosity?

A. Hardly.

Q. All right, now, if you had done that you would have gotten some idea of that, wouldn't you?

A. Sir?

Q. If you had done that you would have gotten some idea about it, wouldn't you?

A. No, I believe it wouldn't have helped any to speak of.

Q. You don't?

A. No.

Q. If you had studied the geology of the field and found that where your formations are dipping downward that your production begins playing out, just as you found over in Gray County and Wheeler County—

A. That isn't—

The Trial Examiner: Wait until he finishes the question.

By Mr. Keffer:

Q. —you would then have considered from that factor that the areas in Quadrant 4, Moore County, and much in Quadrant 3, Moore County, would have been light areas—lean acreage, wouldn't you?

A. If the assumption you make is true, it would be true, but you are comparing something over in Gray County with something over in the northwest part of Moore County.

Q. Oh, no, I'm not.

A. —and right along this edge of Moore County is a highly prolific area.

Mr. March: Quadrants—

The Witness: Quadrants 7 and 8, and down on the edges of the field.

By Mr. Keffer:

Q. That is the exception in the Panhandle field.

A. It is the closest to the area we are discussing.

Q. Well, now, let's see if it is. How about this right here, this right in the corner of Quadrant 3, along Potter County, you find small wells there.

A. I'll agree that there are small wells there but there are large wells here in northern Moore.

Q. Even those large wells don't go right out to the boundary lines of the field.

A. They exist just the same.

Q. They may be a little closer than in some other place, but that tapering off even begins there, doesn't it?

A. I wouldn't say that from memory that it did.

Q. As a matter of fact, isn't the reason they come out close and taper off so quickly that you have a very definite pronounced down-dip there that you don't have around here?

A. Well, I started to make a structural map of the field and never had time to complete it.

Q. You just don't know, then?

A. I wouldn't know as to the local dips there, no.

Q. Now, just what effect, if any, then, have you given to the degree in which one quadrant affects another quadrant, Mr. Hammer?

A. Well, there are various—when you use "degree," there are various degrees, so it is difficult to—couldn't you be more specific? I don't know that I understand you.

Q. Well, maybe so. One quadrant you say does affect another quadrant.

A. I said that there is some effect, that is the reason they were grouped.

Q. Now the degree may be different in each—in different cases. Now, what effect do you give to the variance with which one quadrant might affect another as compared to any other grouping?

A. Well, I think the method we used in balancing these out fairly took care of all of—of any variables in degree as between quadrants that were utilized.

Q. I know you think that, but I am asking you to give the reasons why you think that, is what I am really after.

A. Well, as I have repeated several times, it is a question of balancing and grouping areas adjacent to the quad-

rant in which we wanted to get a production per acre pound from which we could calculate.

Q. As you have explained heretofore?

A. That's right.

Q. That is the only method you have used?

A. That is right.

Q. Now I come back, Mr. Hammer, to large wells you referred to in Quadrant 8, Moore County, maybe some of them Quadrant 7, also Moore County. How do you know those wells are large?

A. Well, suppose I answer that this way—I will have to look at the map.

Q. My point is—I might explain it a little more fully—you state a number of times you paid no attention to the size of the wells, that's the only thing.

A. I said as to individual wells.

Q. Well, those are individual wells, aren't they?

A. Well, it is just another case where I know from having looked at a few of the open flows and having discussed the area that it is a highly prolific area and having even read since I left there of some very large wells being drilled in there, I just naturally know that it is a highly—an area of high potentiality.

Q. Yes, all right. Then you do definitely associate productivity with the size of wells in that area?

A. I said potentiality—

Q. All right.

A. Open flow. I know that the potential there is high.

Q. And you have also said that is a prolific area. Then you associate the two—in that particular spot, I am talking about?

A. Well, there is an association there, yes.

Q. How's that?

A. There is some association, that's right.

Q. That's right. I think there is a very definite association, don't you, between the two?

A. No, I wouldn't say it is very definite.

Q. Now, Mr. Hammer, let's be perfectly frank. Every time you want to make a point by associating them you do, and when you would rather not associate them because it might go the other way, you don't.

Mr. March: I object to that remark by counsel.

Mr. Keffer: Wait until I finish.

Q. Isn't that your reaction to the whole thing?

A. No, that's not my reaction.

Mr. March: I object to the question and move that it be stricken because it is apparent here that the witness testified that when he made this estimate of reserves he didn't have to give that consideration, that he did have some general knowledge of the field, but in the preparation of this exhibit he did not have to locate the wells of large open flow throughout the field.

I realize, Mr. Keffer, you have gone to a great deal of pains here to try to put the witness in the position of accusing him as you have right now. I move that the question and answer be stricken.

Mr. Keffer: I will permit it to be stricken. I have no objection to the question and answer being stricken if you want it that way.

The Trial Examiner: Very well.

Mr. March: You realize I want you to have free cross examination, but not to the extent of deliberately—well, I won't say that. We'll strike that, too, because we might get into a large discussion here. You understand my position, Mr. Keffer.

By Mr. Keffer:

Q. All right, now, refer to Page 14 of your statement, Mr. Hammer. Now, I read from your statement as follows, Page 14:

"Furthermore, it is axiomatic that in anything made up of components having diverse characteristics, an average based on the whole is fallaceous and invalid for the reason that it does not weigh in the characteristics of its diverse component parts."

Now, that being true, you didn't take the field as a whole, did you?

A. That's true.

Q. That is apparent in many, if not all of your quadrants, isn't it?

A. That's right. It was balanced out, not for the field as a whole.

Q. When you balanced out, you mean just what you have said heretofore about balancing?

A. That's right, grouping.

Q. Grouping, that's right, and you had those diverse characteristics in some groups, too, didn't you?

A. Yes, but—

Q. But, nevertheless—oh, pardon me.

A. —in the system of grouping that we used we attempted in every way possible to take into consideration those diverse characteristics locally.

Q. All right, now, right there—but assuming that you did just that, did everything that you could, yet what you did in the various groupings was merely to take an average, wasn't it, that was the best you could do?

A. Well, weighting, yes.

Q. All right, your weighting was your average?

A. Yes, it amounted to an average for each quadrant.

Q. Which is the very thing you say in the statement you can't do without getting a false answer, isn't it?

A. No, I don't think you understand what I meant there.

Q. Yes, I understand perfectly what you said there in your written statement and what you said in answer to my question a moment ago.

A. The point is that we didn't take into consideration the whole. That's the thing—the whole field. We took into consideration the various parts of it locally.

Q. I understand that perfectly, but the various parts that you did take into consideration have the self same diverse characteristics that you have been talking about, that's the only thing I'm asking.

A. They do have diverse characteristics and in the method we used locally, we weighted them out by grouping the areas.

Q. You weighted them out by averaging them?

A. Well, I suppose you can call it averaging if you want to.

Mr. March: By that you mean an arithmetical average?

The Witness: Well we grouped them and took the—

Mr. March: Or weighted average?

The Witness: The weighted average, that's what it was.

Mr. March: As distinguished from an arithmetical average?

The Witness: That's right, a weighted average.

Mr. Keffer: Is that all?

Mr. March: Yes: I beg your pardon.

Mr. Keffer: That's all right.

Q. The weighted average is, of course, as you have already described many times?

A. Yes, sir.

Q. You could have done that for the field as a whole, couldn't you?

A. You couldn't have—no, I wouldn't say you could. You couldn't have applied the—and that's just the point I want to make. You couldn't have applied the characteristics of Moore County and weighted them against the characteristics of Wheeler County, for example, and have got a correct answer for either one.

Q. All right, why not just cut off Wheeler County and figure the two separately?

A. Well, I think as far as Wheeler County is concerned, we took into consideration the local variations and they were weighted out.

Q. All right. Now, we have spent a lot of time on that, Mr. Hammer, and I am going to move on.

As a matter of fact, how do you know you couldn't apply it to the field as a whole? Did you make any effort to?

A. Yes, I made an effort to.

Q. What figure did you get when you did that?

A. I don't remember that. I know it was a figure that—well, I just did it roughly in about an hour one morning.

Q. An hour?

A. Yes, with some figures I had, and it seemed to me that it wouldn't give—well, I just felt that it wasn't right.

Q. It just didn't give you the answer you were looking for?

A. That is not true at all.

Q. Didn't it give you substantially less than you got when you hit upon these quadrants?

A. No.

Q. It didn't?

A. I don't believe it did. I don't remember the figure. I just say I decided that this was the better way to do it and I have stated why I thought it was a better way to do it.

Q. I know you have, but my question is, when you disregard your quadrants and figured the field as a whole you got a substantially less figure than you did when you set up those quadrants and figured them in and then totaled up *you* quadrants. I am asking you that pointed question.

A. As I say, I don't recall what the figure was.

Q. Will you look in your working papers and find out what your figure was?

A. No, as I say, I threw that in the waste basket.

Q. Threw what in the waste basket?

A. What little calculation I had. I didn't even consider it.

Q. Well, how do you know it was wrong?

A. Because we decided that we would get a whole lot more accurate answer—

Q. How did you know what was an accurate answer?

A. Well, we decided we would get a whole lot more accurate answer if we worked the thing out by the local characteristics from one and to the other and then took the summation of those, and that is what we did.

Q. And you didn't even check by applying it to the field as a whole to see if there would be any difference in your answers?

A. Not in general; no.

Q. You didn't check it by any other method?

A. No.

Q. You just shut your eyes to everything except just what you did here?

A. We used this method throughout.

The Trial Examiner: What process, Mr. Hammer, did you go through to make this calculation?

The Witness: Oh, I just had a few figures and I said, "Well, if such and such were true, such and such would be true," and I said, "Well, after all, it seems to me that here we have a great field 120 miles long with all sorts of

characteristics from one end to the other, variables in potential, variables in production per acre pound decline, variables in regional sand characteristics, and if you tried to weight out or utilize the whole field, that would never get a figure that you could apply locally to determine the reserves in any given area that would mean anything."

The Trial Examiner: Well, now, if through a matter of curiosity the Examiner decided that he would calculate the reserves in this field on the basis of the whole field, are there figures now in the record which the Examiner could take and make the calculation that you have just stated you have made?

The Witness: —I believe—well, I wouldn't want to say. I would have to look to check. May I see that sheet, please?

(The document referred to was passed to the witness.)

No, I don't believe they are.

Mr. March: By that you don't mean to say that you haven't presented an exhibit which shows the reserves in the whole field?

The Witness: No.

Mr. March: You have an exhibit which shows the reserves of the entire field, the exhibit marked for identification as Exhibit 186?

The Witness: That's right.

Mr. March: But what you are trying to say is—as I see what the Examiner is getting at is this: that could he take your figures as you have them here in your exhibit and apply another method which would be to take the whole field as a whole, without disregarding all quadrants and arrive at an answer.

The Witness: No, I don't have.

Mr. March: He might arrive at some figures but the figure in your opinion that he would arrive at would be an unsound method and be inaccurate?

The Witness: That is my opinion.

Mr. March: Here is the thing, the witness was asked about the Phillips Petroleum Company and he answered the question.

Mr. Keffer: Who asked him about Phillips?

Mr. March: You did.

Mr. Keffer: He volunteered the statement. I asked him nothing about it. The statement was volunteered on that.

Mr. March: We'll check the record on that.

Mr. Keffer: All right, check it.

Mr. March: The Examiner will remember distinctly that it was agreed by both Mr. Hammer and Mr. Keffer that there was a difference in the application of the quadrants. That type of method was not used in the Phillips—

Mr. Keffer: Let's stay with the record. There was nothing said about any quadrant being used.

Mr. Spencer: Mr. Examiner, perhaps we can shorten this. Let me ask you this, Mr. Hammer: If you handed back to us your working papers on the entire field, we would then have sufficient data to take, to make that computation?

The Witness: I do not have them here. The only working papers that I have is the tabulation that I turned in. I don't even have the working papers for the entire field, I mean outside of the working papers that you have already had.

Mr. Spencer: If you will hand us back the working papers that you gave us prior to the commencement of your cross examination, we will attempt to supply the Examiner with the figure from his working papers that you were asking about.

The Trial Examiner: I don't know that it is necessary, Mr. Spencer. I was merely curious to determine whether or not I could make that calculation on the basis of the figures that are contained in these present exhibits and not a necessary or important thing so far as the Examiner is concerned.

Mr. Spencer: I would put it on this basis: I have more than curiosity on it. I would like to do it.

Mr. March: As a matter of fact, you have already started to do it, haven't you?

Mr. Spencer: You can read my mind pretty well, Mr. March, but not quite that well.

The Witness: Mr. Spencer, may I suggest this: You will recall that I had some difficulty trying to find the tabulations that I turned in. Now, before you go to that trouble or ask anybody else, let me have a chance to search and see if I do have. Now, I don't know that I do have.

Mr. Spencer: That's all right.

Mr. Keffer: Are you through, Mr. March?

Mr. March: Certainly. Pardon me, Mr. Keffer.

By Mr. Keffer:

Q. Mr. Hammer, regardless of the merits or demerits of the pressure decline method, if you take the whole field as a whole, then there would be no question of balancing one quadrant against another in many different groupings and in many different combinations in determining drainage and things of that sort?

A. Read the question, please.

(The question referred to was read by the reporter, as set forth above.)

The Witness: Well, as far as the question of drainage is concerned, I previously testified that I have not made a particular study of the drainage.

By Mr. Keffer:

Q. That's right. Now, just a moment, there. You did say that was the reason you had to balance one quadrant against another, to adjust drainage in and out.

A. Local, yes, but not drainage for the entire field as a whole.

Q. What's the difference, if there is drainage, whether it is local or regional?

A. A big difference.

Q. All right, if you think there is a difference we will let it stand there, but regardless of that, if you had taken the field as a whole, all of those questions certainly would

have been eliminated because there was no drainage into the field or out of the field.

A. Well, I would agree with you that if you had taken it that way that that might have been true.

Q. It would absolutely be true?

A. All right.

Q. Do you want to cut the "might" out of your answer?

A. No, I think I'll let it stay there.

Q. All right. Well, now, Mr. Hammer, in computing your reserves I believe you stated you had to have production figures?

A. That's right.

Q. Even in that one hour's calculation you had to have some production figures to make that one, didn't you?

A. That's right.

Q. And you got those figures, I believe, from the Texas Railroad Commission?

A. Yes, they were taken from the records of the Commission.

Q. But at the time you—well, I'll ask you this: Do you know to what extent that those records might have been incomplete?

A. From 1935 on I think they were quite complete.

Q. They were complete as to metered gas?

A. That's right.

Q. You do know that gas is used in flowing wells?

A. That's right.

Q. Gas is lost in drilling wells?

A. That's right.

Q. And various losses of gas of that character which is not reported to the Railroad Commission?

A. I think that is true.

Q. That's right. What is reported is the metered production?

A. That's right.

Q. All right, don't you think it might have been well to have made some inquiry to determine about how much of that gas was going that way, for the sake of accuracy in your figures?

A. Well, it might have been advisable, but after you had done it you couldn't be at all sure of the figures. It wasn't metered. It would be someone's guess.

Q. I appreciate that, but couldn't you have made a conservative guess on it? You knew it was something.

A. I doubt if you can make a conservative guess on an area as large as that. The point there, Mr. Keffer, is this, that the very fact that we didn't utilize that wasted gas is an added factor why our reserve tends to be a minimum reserve.

Q. That could be very true, but it might show some other things, too, mightn't it, Mr. Hammer?

A. I don't think it would show anything. In other words, the percentage of gas that has been wasted over the last five years and utilized for other purposes than unmetered gas would be so small in relation to the whole that it wouldn't be important. Now, prior to 1935 that's a different story.

Q. But you didn't consider any of it prior to 1935?

A. Well, I didn't consider anything prior to 1935.

Q. That's right, you started with 1935?

A. That's right.

Q. But if those factors, had they been considered, would have developed some other matters pertinent, do you think it would be certainly permissible for us to take that into account, wouldn't you?

A. What things are you talking about?

Q. This gas that you didn't take into consideration that went into the air, and unmetered.

A. I don't understand the question.

(The question referred to was read by the reporter, as set forth above.)

The Witness: Well, I am not judging what you may take into account in your consideration.

By Mr. Keffer:

Q. Oh, I understand, but you as a geologist wouldn't say that would be farfetched?

A. I would say it would be better if you had them, but not being able to have them and making an estimate or a guess from this fellow and another fellow, you might get four or five different fellows and get four or five different answers.

Q. You looked at that sort of like dry holes in as much

as you don't know of more than six inches being dry, you just ignored it.

A. Yes, realizing when I did ignore it that it would have a tendency not to inflate the reserve factor.

Q. You have the acre factor; you have to multiply the acres, it would have to some extent.

A. No.

Q. Now, Mr. Hammer, during the pariod from 1935 to 1939 there were some wells that were not connected to gasoline plants that were producing casing head gas and blowing it into the air. Did you make any investigation of that?

A. During the years 1935 to 1939?

Q. Yes, in the gas area.

A. No specific investigation of gas blown, because—

Q. If there was any of that you have ignored that?

A. We were informed by the engineers of the Texas Railroad Commission that while in the early part of 1935 and running on, we will say, into 1936, there was, but that practice by the time 1938 or 1939 came about had largely ceased to exist.

Q. Well, it was very much less but it still existed to some extent, didn't it?

A. Well, that is all right—no, again that would be a guess.

Q. In other words, you more or less assumed it didn't exist and didn't make any particular investigation of it?

A. I think that is true.

Q. All right.

A. If that is true that would give us a factor that would tend to reduce the estimate of reserve.

Q. That might be very true, but again I say it might show some other things also?

A. I don't know as to that. I doubt it.

Q. All right. I believe you have already stated that you did not obtain any figures for gas used for fuel and drilling operations?

A. Metered gas reported to the Commission was what we used.

Q. Ordinarily gas used for drilling operations is not metered, is it, unless you are buying it from some other producer?

A. I don't know what the practice is. If you buy from another producer, unless you buy it on a flat rate basis, it is metered.

Q. That is right. Frequently that happens, it being charged for at the rate of so much per day?

A. That is sometimes done.

Q. It is so much on a rotary operation and so much on a standard operation?

A. Sometimes it is metered.

Q. Sometimes it is metered?

A. Yes.

Q. And I take it you made no particular inquiry into that?

A. No, we didn't use that figure.

Q. Did you make any inquiry as to what it was?

A. I think we have seen some figures, maybe, during one year or two that somebody had estimated, estimating the amount of gas for those purposes, but as a general thing we didn't try to get it.

Q. If you had all of those volumes of gas and knew pretty well what they were and you were deducting that from the original reserve as you found it, you would have a smaller figure than deducting the figures which you have compiled, wouldn't you?

A. If I deducted—you mean—

Q. Just as a matter of subtraction.

A. From the original?

Q. From the original.

A. Yes, you would have a smaller figure.

Q. That way you could give a lesser figure rather than a higher figure for remaining gas reserves?

A. That isn't the method we used.

Q. I appreciate that, but maybe somebody might use the other method, and I want the record to show this gas and your omission of it. That is all.

A. Your statement under that condition, if you had a lesser amount that actually came out of the ground, it would make a difference.

Q. All right, now, would it interest you to know that in 1935 gas blown into the air, gas used in drilling, casing head gas not treated and blown into the air, ran as high as seven per cent of the total field production?

A. It would be interesting, but may I ask this: What percentage of that came from the area in which the Canadian River's acreage is situated?

Q. We are talking about the field-wide figure.

A. I would be interested more to know what percentage of that gas came out of those quadrants in which Canadian River Gas Company has its acreage.

Q. Well, what makes a difference where it came from? It came from the reservoir, didn't it?

A. It makes a lot of difference.

* * * * *

The witness stated that he was pretty certain there had been more drilling in Moore and Potter Counties in recent years than in other portions of the field and that usually when there is more drilling you have more production and that as you have more production you have more rapid pressure declines in the future that you had in the past, and that he would expect the pressure decline in Moore and Potter Counties to accelerate.

The witness was then asked that if you had a pressure decline of so much per year for the past five years that this is not very positive proof that there is not going to be a greater pressure decline for the next five years, or any number of years in the future, and he answered that he was not endowed with power to look into the future to see what would happen.

The witness then stated that if he had factual data for another five years perhaps his present estimate would be altered.

The witness stated that when an averaging process was utilized, whether in a quadrant or in the field as a whole, in which areas of prolific production are averaged with areas of lean production, you get a false answer if the variations are very great. If you have absolutely the accurate pressure at a given date, and you have the given pressure at another date, and you have the volume of production during that intervening period, you have all of the tools you need to apply the pressure decline method. If the conditions were ideal you would get the same production per pound loss in pressure for any given period. If you had a reservoir where there was no factor of permeability, such as a room full of gas and draw it out, you would be approaching ideal conditions but those conditions do not exist in the Texas Panhandle Field. The witness stated, however, the pressure decline method might be utilized notwithstanding the absence

of ideal conditions because the divergent conditions were all weighted out.

The witness did not agree that if you got a different rate of production for every pound lost in pressure for each period that this demonstrated that the pressure decline method was not working properly, but said you would get the same answer every time if you had a fully developed field where every one of the wells was finished. You would have a better condition and would get a better answer. He acknowledges that his estimate is not perfect, but does think it is the best method and approaches more clearly the true condition than any other method of estimating reserves.

It is his opinion that if the basic data is correct, there is not going to be any great variation in the estimates from year to year as compared to production and pressure drops.

Every time you drill in a new well you get an added pressure, that is, an added pressure point you never had before. You also get an added potential that you never had before. You start taking gas out and you get an added volume of gas, and as time goes on you do have these changes, but they should weight out very closely in the method I have employed.

If you computed the reserves last year, for example, and got the correct answer, then you could drill wells from now on until "dooms day" and that answer wouldn't change if everything was perfect, that is, if you had an ideal situation.

The witness realizes that a slightly different answer is obtained each year that the pressure decline method is applied, but states that you cannot take one year or two years in the Texas Panhandle Field and even hope to use the pressure decline method. You must have a longer period, and the longer the period the better, and it will not be long until you will obtain a curve that will stand up throughout the life of the field. We have not reached that situation yet because there are certain areas that have not been drilled. This has an important bearing. If a well is drilled in a 435 pound area and you start producing gas, a new condition locally is created which will have its effect. It gives you another factor and the application of it will give you a more nearly correct answer. It is the witness' opinion, however, that the undrilled acreage that has a pressure of 430 pounds

is relatively unimportant when compared with the field as a whole.

The highest pressures at this time are in Moore and Hartley Counties, all along the southwestern part of the field and up around the western portion until you get near the northern part of Moore County, all around the edges.

Going all along the southern line of the field, starting from Wheeler County, going west and including an area along the edges of the field, back several miles, and continuing until you reach the northern tip of Moore County, a distance of probably 175 miles, you have an area of high pressure in general—much higher than an average of the field as a whole, which includes all of the area which witness admits is of doubtful productivity. That is, the area in question includes the area in which the volume of gas in place is doubtful—an area of doubtful productivity, and it also includes the area of high pressure.

The witness then testified with respect to the weighting process he used in determining the average weighted pressures and explained what he meant in stating that all of the diverse factors were weighted out in his process. He did this by taking the area between each of the isobars in a given area. He computed the area as accurately as he could and then took the average pressure for the area between two of the isobars and mutiplied the average pressure by the area. He then took the summation and divided that sum by the total acreage in a quadrant, and when he did that he got an average weighted pressure for the quadrant.

This was illustrated by referring to Quadrant 1, Potter County. The area included within the 430 pound isobar lines was computed as to acres and the number of acres in this area was multiplied by 430. The 430 pound acreage is in the southern part of the quadrant. He made the same computation for the area between the 360 and 370 pound isobar lines in the northern part of the quadrant. He determined the acreage in this particular segment and multiplied the pressure obtained by the number of acres, but refused to state that he got a bigger product, acre for acre, in the 430 pound zone than he did in the 360 to 370 pound zone. This was then illustrated by assuming that the northernmost area which lay between isobar lines 380 and 370 contained 1,000

acres, and that the average pressure in the area was 375 pounds. This 375 multiplied by 1,000 would give 375,000 as a factor. The southernmost segment which had a pressure entirely above 430 was also assumed to contain 1,000 acres, and he arrived at his factor by multiplying 430 by 1,000 and got 430,000. The witness said that this is what he did.

He was then asked which segment contributed the most weight acre for acre, the north or south. He answered that neither one contributed more than the other but stated that they both contributed the same notwithstanding the fact that after his arithmetical process had been completed one had a factor of 375,000 and the other 430,000, but he said that when you add all of these up and divide by the total acreage, then balance these against the entire acreage, you would get an average figure for all of them. The average pressure in the illustration given would be 402½ pounds weighted average pressure in accordance with the witness' method of averaging, being 375,000 plus 430,000 divided by 2,000, the total acreage. The witness insisted however that neither segment contributed more than the other to the total weighted average because the inconsistencies were weighted out by his method.

With further reference, by way of illustration, to Potter County, Quadrant 1, the southernmost segment in this quadrant contains a 430 pound pressure, while the northernmost segment lies between the 370 and 380 isobar lines, which gives an average pressure of 375 pounds. The weighting process utilized by witness was to multiply the acreage by the average pressure in each segment and then add up the products and divide by the total acreage in the quadrant to secure the total weighted average pressure for the quadrant, and the weight that was given the northern segment in the averaging process was the actual acreage times the actual rock pressure and that was true of every other segment in the quadrant, and the weight that was given the southern segment referred to in Quadrant 1 was the actual acreage times the actual rock pressure. The witness then stated, however, that this did not mean that the higher the pressure the more weight was given to the acreage in any particular segment, but again reiterated that as to each segment he multiplied the pressure by the

acreage, and that he did this for each segment in each particular quadrant, but again stated that it doesn't follow from this that the segment with the higher pressure contributes more to the total than the segment with the lowest pressure.

The witness then again outlined his method for determining weighted average pressure and that was by simply taking the areas in acres between the isobars and multiplying the acreage by the pressure which gave a pressure acreage factor. He then added or totaled all of these products for each segment in a quadrant and divided that figure by the total acreage in the quadrant which he said weighted the thing out completely and gave an average figure for the entire area in the quadrant. The procedure was then illustrated by assuming a quadrant contained a total of 2,000 acres, 1,000 acres having a pressure of 200 pounds, and the other segment, being the remaining 1,000 acres, having a pressure of 400 pounds. In order to get the average weighted pressure the 200 pound segment is multiplied by 1,000, giving 200,000, and the 400 pound segment is multiplied by 1,000, giving 400,000. This totaled 600,00. This was then divided by 2,000, the total average in the quadrant, which gave an average pressure of 300 pounds, and under this hypothetical case, the 400 pound segment contributed just twice as much in the weighting process as the 200 pound segment. The witness further stated, however, that this gave an erroneous figure, but if they are cut down to 10 pound differentials in pressure the error could not be more than 5 pounds.

The matter was then illustrated by assuming a quadrant with a 10 pound pressure differential, each segment containing 1,000 acres and ranging from 200 pounds to 400 pounds with 10 pound differentials all the way through, that is, starting at the lowest, 200 pounds with 1,000 acres, 210 pounds with 1,000 acres, 220 pounds with 1,000 acres, and so forth in the same manner until 400 pounds is reached, which also contains 1,000 acres. The witness then figured all the way through and arrived at the weighted average pressure by multiplying the pressure in each segment by 1,000 acres, being the area of each segment, then totaling the various products and dividing by the total acreage in the quadrant in order to get his total weighted

average pressure. By this method of calculation, which was the method used by the witness in making his reserve estimates, it was demonstrated that the 200 pound segment contributed 200 times 1,000, or 200,000 in the weighting process, and the 400 pound segment contributed 400 times 1,000, or 400,000 in the weighting process.

The witness stated that of course if you consider only the two segments you would have a distorted figure for the reason that one would have contributed twice as much as the other, but this had no application to the actual problem because he didn't take just two segments in making his reserve estimate but averaged all of them, from 200 to 400, and got a weighted average figure and in this manner assigned the same value to all of them, and thus weighted the entire error out of it. He says that when each segment was considered as above outlined, one segment had no more effect upon the final answer than any other segment because they each had the same value after he had averaged or weighted the various factors for each as stated. He was then asked if the 210 pound segment didn't contribute a little more to the final answer than the 200 pound segment, and the 220 pound segment a little more than the 210 pound segment, and so on all the way up the scale to the 400 pound segment, and he stated that that was correct, but again stated that notwithstanding this the 400 pound segment did not contribute twice as much as the 200 pound segment because they were weighted in with all of the other segments.

Quadrant 1, Potter County was again referred to for illustration. The witness stated that the northern segment of Quadrant 1 had 270 pounds pressure and the southern segment 430 pounds pressure, which is shown by map, Exhibit 179. The witness was then asked whether, if, as a matter of fact, the 270 to 280 pound segment in this quadrant was highly productive, and the 430 pound segment right down on the edge of the field in the southern part of the quadrant was very lean, this would not result in unduly stressing the lean acreage. He said this was not true because in considering all of the intervening segments he had weighted out the difference and flattened out the pressures for the entire quadrant. He stated it was true that even in this process the southernmost segment

(which was assumed to be lean) counted much more, acre for acre, than the northernmost segment (which was assumed to be rich) but that when all of them were averaged in they were all weighted out and had the same value.

He was then asked if his answer would not be correct only on the theory that the acre content of the gas in place was just the same in each segment because then if this were true he would get a correct average, but only if this were true, and that in that case of course the 400 pound segment would be given just twice as much weight as the 200 pound segment, but would be entitled to just twice as much because the original acre content was just the same and the pressure was twice as great. The witness stated, however, that this was not correct and said it would work even if you had drilled a dry hole in some of the acreage because this was all weighted out in considering each of the segments as hereinabove explained. He stated that in other words, you simply took the high pressure area and balanced it against the low pressure area, and the low and balanced it against the high, and got the weighted average.

The witness was then asked that in the application of the pressure decline method if he applied it and got a certain pound drop in pressure for so many billion feet of production which came mostly from the rich areas of the field, and then averaged that in with the lean areas that had a high pressure, but which had had no production and had not been affected by drainage, that this would necessarily give him a distorted figure. He answered that you would not get a distorted figure because the high pressure areas had been averaged in with the more prolific lower pressure areas in the balancing and weighting process as above outlined.

There was marked for identification Exhibit 188 which was later received in evidence.

For Demonstrating Pressure-Decline Method.

Total 60,000 "

POWER COMMISSION DOCKET NO.
NO. 188 (FOR IDENTIFICATION)
NTIFIED

In the accompanying example all pressures are assumed to be absolute. Deviation from Boyle's Law is ignored, and the space in the connecting lines, gauges, and meter is considered to be negligible.

C. Ray Hughes.

Exhibit 188 is a drawing portraying three containers, each of which contains 20,000 cu. ft. of gas at 400 pounds pressure, and each contains the same surface area, assumed to be 1 acre. If 5,000 feet of gas were withdrawn from each of them this would reduce the pressure one-fourth in each of them. This would give a pressure of 300 pounds in each, which would be the weighted average pressure.

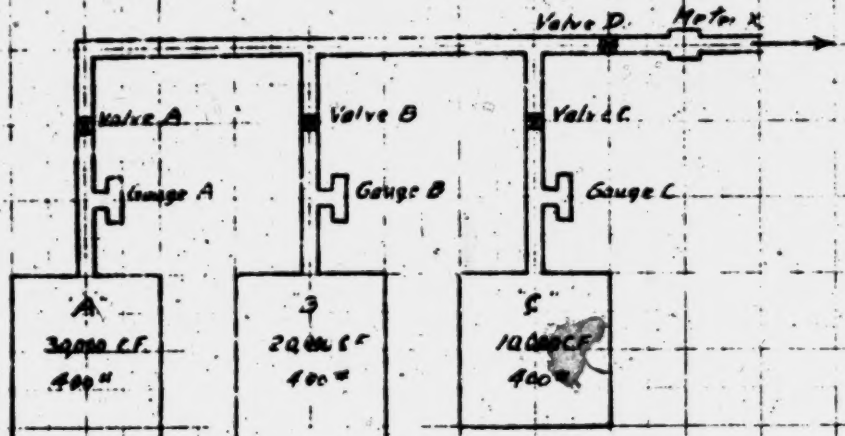
Still referring to Exhibit 188, the matter of pressure decline was again illustrated by producing the entire 15,000 feet of gas from Container A. It had 15,000 feet to begin with and would have 5,000 feet left. Three-fourths of the gas had been produced and, therefore, only one-fourth of the gas and one-fourth of the pressure would be left, or 100 lbs. pressure. The other two cylinders had no gas produced and were still at the original 400 pound pressure. The average pressure for the three would be 300 pounds. In producing 15,000 cubic feet of gas 100 pounds of pressure was left. Each pound of pressure lost represented, therefore, 150 cu. ft. of gas. There was a 400 pound pressure to start with. Therefore, to determine the original content 150 would have to be multiplied by 400 which would give a total of 60,000 cu. ft. This is the known original content in the three containers. This problem demonstrates that it doesn't make any difference how you take the gas out of the containers if the containers are all of equal size. It was the witness' thought, subject to further check, that you could take any other combination of containers of equal size and you would always come out with the same answer on the application of Boyle's Law. The containers, of course, represented a perfect condition and the answer was absolutely correct. It was the witness' opinion that it would work almost as well with respect to conditions that actually exist in the field, that is, if there was a variance in the acre content it would still work if the variance was weighted out just as he had done it and as he had theretofore explained.

There was then marked for identification Exhibit 189, which was later received in evidence.

Exhibit No. 189

For Demonstrating Pressure Decline Method

Chart 2.



Total Assumed Quantity of Gas

Container	A	30,000 C.F.
"	B	20000 "
"	C	10000 "
	Total	60000 "

In the accompanying examples all pressures are assumed to be absolute, deviation from Boyle's Law is ignored, and the space in the connecting lines, gauges and meter is considered to be negligible.

C. Dee Hughes.

RAL POWER COMMISSION. DOCKET NO.
BIT NO. 189 (FOR IDENTIFICATION)
IDENTIFIED

RAL POWER COMMISSION
No. G-118-121-124
g. Exhibit No. 189
troduced

Exhibit 189 illustrates 3 containers, A, B, and C, Container A having 30,000 cubic feet; Container B having 20,000 cubic feet; and Container C having 10,000 cubic feet. Each have a 400 pound pressure and each have the same areal surface, which was assumed to be an acre in each case. The witness stated that the variance in the Texas Panhandle Field as to acre content was certainly as great as the content assigned to each container and that, as a matter of fact, his investigation showed that the actual variance per acre content in the field was greater than that shown in the illustration.

Another illustration was then made with respect to the containers in Exhibit 189. This illustration assumed that 15,000 cubic feet were taken out of Container A, which left in it a pressure of 200 pounds. Nothing was taken out of the other two containers. The witness then arrived at an average weighted pressure for the three containers; that is, by taking the 200 pound weighted pressure in Container A, the 400 pound weighted pressure in Container B, and the 400 pound weighted pressure in Container C, the average weighted pressure would be 333 1/3 pounds. The original pressure in each container was 400 pounds, therefore, there was a total loss of 66 2/3 pounds in weighted average pressure. There had been 15,000 cubic feet of gas produced, or 225 cubic feet for each pound drop in pressure. It follows, therefore, that one pound of pressure represented 225 cubic feet of gas, and that in order to determine the original content in the three containers this 225 cubic feet would be multiplied by 400 which gives a total of 90,000 cubic feet as an estimate of the gas in place based upon the application of weighted average pressure to production.

As a matter of fact, the containers contained originally only 60,000 cubic feet, and therefore the estimate was just 50% greater than the actual volume of gas in place.

The witness stated that the error came about by reason of the fact that gas was withdrawn only from one of the containers, but he would like to have a little time to think the matter over.

Where the volume of gas was just the same in each of the containers the pressure decline method, or the appli-

cation of Boyle's Law, worked to perfection, but when the containers contained different volumes of gas and the average pressure was obtained by weighting one surface area, as in Exhibit 189, the pressure decline method, or Boyle's Law, gave an erroneous answer.

The witness stated, however, that in the example the weighting was unity against unity, but it was not always unity against unity in the field in so far as acreage was concerned. He said he used unity against unity, unity being quadrants, in estimating the field, but not in the sense that he was talking about, the difference being that you can only go out so far, and if you weight in acreage from which there has been no production, you are bound to get a lesser weighted production per acre pound than if you don't use it, but in making the estimate for the field the witness stated that he did weight in acreage that didn't have production and then upon being asked if that wasn't what was done in the example, he stated that he desired to reserve his answer.

The witness then stated, after a short recess, that he desired to make an additional explanation, and that was that the container example was not representative of the conditions in the field. If the three containers were connected, then it would approach field conditions, otherwise it would not be representative at all. The witness then stated that if the three containers were connected it would, in general, represent the conditions in the field.

Another example was then given. The containers were all connected as requested by the witness, and some gas taken out of each container. It was assumed that 15,000 cubic feet of gas was produced out of container A, 5,000 cubic feet out of Container B, and 2,000 cubic feet out of Container C. Each container was opened up and this was the total volume produced from the three containers, representing the field as a whole. The witness then solved this problem by determining the weighted average pressure on the three containers by weighting on areal surface alone as he did in making his reserve estimates. This indicated a weighted average pressure of 273.3 pounds, or a loss in pressure of 126 2/3 pounds. There had been a total aggregate production of 22,000 cubic feet, which resulted in 173 feet per pound loss of pressure. This then, multiplied by

400, the original equilibrium pressure, would result in a total estimate of gas in place of 69,200 cubic feet. The actual content was known to be 60,000 cubic feet. The estimate, therefore, was erroneous.

The witness then stated that instead of having three containers in the field, there were an infinite number of containers.

The witness then stated that the last problem represented a situation where the pressures were different in different areas and the quadrants were different with respect to the volume of gas in place in each quadrant, and that where this situation exists you can take any set of figures you desire and you will never get the right answer.

The witness then stated that the containers represented different reservoirs of certain sizes, which situation also existed in the field. It was then explained to the witness that the only difference in the illustration and the actual field condition was that the correct answer was known and advanced for the purpose of checking or testing the method where you have quadrants that vary as to productivity and where pressure differentials exist at the same time from one side of the field to the other. The witness stated that there was a further difference and that was that you have an infinity of reservoirs in the field.

The witness was then asked if the result would have been precisely the same if each container had been assumed to have 500,000 surface acres instead of one, thus giving the total acreage a figure that corresponded approximately with the total acreage in the field. The witness again stated that even under that situation that would still not take into consideration the infinity of reservoirs in the field. It was then called to the attention of the witness that there were wide areas in the field from which a single cubic foot of gas had never been produced and that this was shown by his Isobaric Map, Exhibit 179, and that was the basis for the first illustration given where some gas had not been produced from some of the containers. His attention was then called to the fact that the witness had stated in effect that the problem could be solved correctly if some gas was taken out of each container, and that a problem had been worked out on this basis but still an erroneous answer

had been reached. His attention was also called to the fact that the range in pressure in the example given, which was from 200 pounds to 320 pounds, constituted a much less differential than the actual differential existing in the field, and that the range per acre content only varied in the ratio of three to one, where the actual range in the field ran as high as six or seven to one, and that if actual field conditions had been taken, the answer would have been more erroneous than it was. The witness answered that he didn't think so, although he did say in this connection that actual pressures in the field ranged from about 90 to 430 pounds, and the per acre productivity was in excess of three to one.

The witness then was handed a set of calculations made from the witness' working papers and he was asked to verify the figures contained in the calculations. He could not verify the figures on the witness stand but stated that he would do so later. The witness did admit, however, that the basic figures from which the computations were made were all taken from his working papers. These calculations were later introduced in evidence and marked for identification as Exhibit 264.

Witness HAMMER further testified on cross examination, Vol. 58, pp. 8110 to 8253, inclusive, as follows:

The witness read into the record the weighted pressures for the entire field for the period from 1935 to 1939, inclusive, and also the total cumulative production during that period, which was as follows:

Year	Pressure	Cumulative Production
Aug. 1, 1935	369.25	
Aug. 1, 1936	360.74	615,778,940 Mcf.
Aug. 1, 1937	352.02	1,215,791,981 Mcf.
Aug. 1, 1938	343.01	1,832,231,200 Mcf.
Aug. 1, 1939	332.98	2,430,370,036 Mcf.

The witness stated that the pressure for each year was determined as of August 1 of that year, and that the production figures were from August 1 of one year to August 1 of the next. For example, the 1936 production figures represent the metered production from August 1, 1935, to August 1, 1936. The production figures were also cumulative for the period, that is to say, that the 1937 produc-

tion was added to the 1936 production and so on through the period, and that to obtain the production for any one year it would be necessary to subtract the cumulative figure from the next following cumulative figure. The pressure base was 14.65 pounds per square inch absolute, and the calculations did not include Wheeler County Quadrant 1. The total acreage for the field as determined by the planimeter calculation was 1,478,143 acres. The witness then stated that his estimate for the field of original gas in place, calculated to an assumed abandonment of 25 pound gauge at the well head, was 29,277,000,000 Mcf., but he had not calculated it to zero pounds well head, but stated that the original figure to zero pound well head could be determined by dividing the figure above given by 465 and multiplying the result obtained by 430, the original virgin pressure in the field, which would give approximately 31.046 trillion cubic feet of the original gas in place to zero pounds which would be all of the gas in place before there was any production on a 14.65 pound pressure base.

Witness HAMMER further testified (Vol. 58, pp. 8115-8141) as follows:

Before I get into that, let's go back again just a moment to the examples that we were working on yesterday. I will go back to the last example I gave you yesterday which was based upon Exhibit 189, being Chart 2 of the illustration demonstrating application of the pressure decline method. I believe on that last computation—

A. Just a moment. I will have to locate my papers.

Q. All right.

A. All right.

Q. Rather than the last illustration I gave you I think I will go back to the first one I gave you on that exhibit in order to facilitate the computation. The one I gave you on the spur of the moment figures out in some odd figures and it takes quite a little while to compute it, but I think this will illustrate the point just as well.

On that first one I gave you—

A. That is one hundred—

Q. I gave you two on 189; the first illustration was where all of the production was out of A, and the second one was where some of it was out of A, some of it was out of B,

and some of it was out of C. I am going back to the first one I gave you. That was 15,000 cubic feet production as I recall it, out of A, A alone, was it not?

A. I believe that is true.

Q. I am sure that is right. When you computed that out on the pressure decline method and weighted them through you got a total content of 90,000 cubic feet against a known content of 60,000 cubic feet, didn't you?

A. By your method of computation.

Q. And by your method, too?

A. No, I followed your method of computation.

Q. Was anything wrong with my computation?

A. Several things.

Q. I thought we had settled all of those things. What was wrong with it?

A. Well, now, we are referring to where you only take gas out of the one place?

Q. That is right.

A. Well, here is one thing that is wrong with it—

Q. How's that?

A. Here is one thing that is wrong with it—

Q. All right.

A. —and it is this: When a certain amount of gas is withdrawn from a cylinder the same *same* cubical content of gas remains in the cylinder but at a reduced pressure. In order to apply a 400-pound factor to calculate back to original volume it would be necessary to withdraw all of the gas from the container; the pressure decline would then be from 400 pounds to zero.

Now, in your case I didn't draw all of the gas out, and you utilized 400 pounds. What you should have utilized was your 200 pounds and you didn't do it.

Q. Do I understand—

A. In other words, you were using a factor to get your—it was about twice as large as it should have been.

Q. Will you explain what you mean by that?

A. I have just explained it. If you take the gas out of the container and you get your 200 pounds—

Q. That is right.

Mr. March: Go ahead and illustrate it. Go ahead and complete your answer.

The Witness: To use your 400 pounds you would have

to take all of the gas out because that is the total pressure originally in it. To use your 400 pounds you would have to take all of the gas out and multiply by 400.

By Mr. Keffer:

Q. You are trying to say you can't compute that until all of the gas is taken out?

A. No, not at all. What I am saying is that you used the wrong factor—it was just half the size you should have had.

Q. I started out with a 400-pound pressure all the way through.

A. Yes, you took out half of the gas and had 200 pounds left and then multiplied that by 400.

Q. Multiplied what by 400?

A. The amount of gas you had taken out.

Q. How is that?

A. The amount of gas you had taken out.

Q. Mr. Hammer, let's take that container. Let us assume that you don't know how much is in it to start with and you have taken out 15,000 feet and you have 200 pounds—you had 400 pounds pressure to start with and you have 200 pounds pressure left.

A. All right.

Q. You tell me how much was in there to start with. You don't know that and you are to calculate that from the tools I have given you.

A. Now, your statement was that I had 400 pounds to start with there?

Q. 400 pounds to start with.

A. And you take out gas enough to bring it down to 200 pounds?

Q. No, we took out 15,000 feet of gas and we took our pressures again and found they were 200 pounds.

A. All right.

Q. You tell me how much gas was in there to start with, calculated out just as though you didn't know the answer before you started.

A. Are you utilizing one cylinder alone and paying no attention to the others?

Q. No. A is the one I gave you.

A. Well, you have taken out 15,000 cubic feet.

Q. That is right. We agree on that.

A. You had a drop in pressure of 200 pounds.

Q. That is right.

A. You multiply that 15,000 by 2 and you get your 30,000, your original—

Q. You do what?

A. You get your 30,000—wait a minute.

Q. Can't you figure that out in your head, Mr. Hammer, in about thirty seconds?

Mr. March: Now, Mr. Keffer, quit haranguing the witness. If you want him to figure out the problem, give him sufficient time to do so.

The Witness: I can't figure that out in any short time. If you will give me a little time I will do it.

By Mr. Keffer:

Q Let me figure that for you. I believe I am better on those things than you are. We had 15,000 feet that went out of the area. We knew that as we have that figure. Isn't that true?

A. You took out 15,000.

Q. We knew we had 400 pounds to start with, didn't we?

A. That is right.

Q. We knew we had 200 pounds left, didn't we?

A. Yes, if you took out half of the gas.

Q. We knew we lost 200 pounds pressure, didn't we?

A. Yes.

Q. We knew for every pound of pressure left we had to produce 75 cubic feet of gas, didn't we?

A. That is 15,000 divided by 200.

Q. 15,000 divided by 200. We had 15,000 lost in cubic feet and 200 pounds lost in cubic feet and so it is just 200 divided into 15,000, isn't it? Is that 75 pounds or is it 750? Is that right?

A. I thought you had figured it out and I wasn't working on it.

Q. I will divide it out and see what it is. I may have left a cipher off.

A. It is 75 cubic feet.

Q All right. Then would we multiply that by—we would mutiply that by what to find the original content?

A. By the pressure of 400 pounds.

Q. By 400, wouldn't we?
A. Yes.
Q. And you would get what?
A. 30,000.
Q. So you do multiply by 400 after all, don't you?
A. Yes, under a condition like that.
Q. Yes, that is right.
A. That isn't analogous to our field problem.
Q. All right, we will get to that again. I thought we had covered that. That is a very simple application of Boyle's law?
A. For that application.
Q. And any high school student who had a very elementary course in physics could work that problem during an examination period, couldn't he?
A. Well, that statement is open to question.
Q. All right, we will let you question that one.
A. It is a problem in physics and not ordinary mathematics.
Q. How's that?
A. It is a problem in physics and not ordinary arithmetic.
Q. It is a problem in physics?
A. The only place physics comes into that is where you learn about Boyle's law, how Boyle's law applies.
Q. There isn't any question about the very simple problem we solved there, is there?
A. Not as it applies to the one cylinder.
Q. And we did have to multiply by 400 after all, didn't we?
A. For that particular case.
Q. That is right. So you want to retract the statement a while ago that when I multiplied by 400 I should have multiplied by 200; that was an erroneous statment, wasn't it?
A. Talking about this individual cylinder now?
Q. How's that?
A. Talking about this individual cylinder now?
Q. Yes, this individual cylinder—"quadrant," I believe is the name. I like that word better.
A. You can call it anything you want to.
Q. It my child; I can name it anything I want to.

A. I am still not sure—I would like to reserve my answer to your question.

Q. All right, how long do you want to reserve your answer, Mr. Hammer?

A. Well, I don't know. It will be just as soon as we have a five—or ten-minute recess so that I can get in a corner and figure it out.

Q. We will probably recess after while and then you can see if you can find a different answer to it.

Now, Mr. Hammer, let's take another very simple problem. You have this container here where you—this quadrant. I am going to insist upon if being called a quadrant—where you had a 400-pound pressure to start with. You know it has produced 15,000 cubic feet of gas, and you know you have 200 pounds of pressure left. Those are all definite figures and there isn't any estimate about them. Now, I want you to figure for me just how you would determine the remaining content of the gas in that quadrant. You have all the figures you need to determine that, haven't you?

A. You are talking about what?

Q. Just one cylinder, Quadrant A.

A. Well, you have to weight the problem against your acreage factor.

Q. All right, we will say it contains one acre or a hundred thousand acres or a million acres. You can compute any acreage you want to.

A. Will you read that question again, please?

(The question referred to was read by the reporter, as set forth above.)

The Witness: Now, let's get this problem straight.

By Mr. Keffer:

Q. All right, let's get it perfectly straight.

The Trial Examiner: Mr. Hammer, maybe I can help you.

The Witness: All right.

The Trial Examiner: On this previous computation you just made for Mr. Keffer I believe you arrived at what Mr.

Keffer seems to call "Quadrant A of reserves in place, the sum of 30,000 cubic feet original reserves in place." Now, you have produced 15,000 cubic feet and I believe Mr. Keffer's question is "what is the remaining reserves?"

Mr. Keffer: No, it isn't quite that. The question is, having those three known factors which I gave, that is, the original pressure, 400 pounds, the pressure of 200 pounds, the production of 15,000 cubic feet, then what would he do or how would he compute the remaining reserve today? He did that over the whole Panhandle field and I want to see how he did it on this particular area.

Mr. March: That is your assumption. You are taking this problem now.

Mr. Keffer: It is the principle that is involved.

The Witness: It isn't an analogous case, it is your problem, not mine.

Mr. March: We are working on your problem, these three cylinders, now.

Mr. Keffer: I want to have the witness tell me how much gas I have left there. I have to know that.

The Witness: Well, now, to zero, that is what you are after?

By Mr. Keffer:

Q. Remaining zero gas well head.

A. You would take out an additional 200 pounds—

Q. How's that?

A. An additional 200 pounds—I say, if you take out an additional 200 pounds of pressure—

Q. You wouldn't have anything left, would you?

A. That is right.

Q. Still you haven't answered my question. I am going to make a contract to serve Denver with gas when this present one expires and I want to know if I have enough gas there to do it. That is a very important problem to me and I want you to tell me as I have employed you as my geologist.

A. Well, if you are going to take all of your gas out of this one cylinder—

Q. Yes, that's all I have. That's the only reserve I have.

A. That all comes out of this one cylinder.

Q. That's right.

A. And you weight it against your one acre, your unity acre

Q. Yes, one acre or a hundred thousand acres. You can put any acre on it you want to.

A. On the decline there you would have just 15,000 cubic feet.

Q. We knew the answer to start with. I want to see the calculations that you go through to get that answer. Just explain briefly what you did to arrive at that 15,000.

A. Well, you do the same as you did in the first part of your withdrawal.

Q. Just give it to us step by step.

A. All right, when you draw out your 15,000, you had the drop of 200 pounds pressure.

Q. That's right.

A. Out of this one cylinder.

Q. That's right.

A. Then if you draw out all of it and get zero, assuming that you can get to zero, and you have taken out all the gas—

Q. That's right.

A. Why, you would have an additional drop of 200 pounds.

Q. That's right.

A. And at whatever pressure base you use in your calculation you would have the same 15,000 cubic feet.

Q. Now, is that the way you figured the Panhandle field?

A. Well, we figured the Panhandle field according to principles of Boyle's law, yes.

Q. Now, the only thing—that is the thing. You don't have to do any weighting here because you have got just the one quadrant. You don't have to do any weighting or balancing and the pressure is unifrom over the entire quadrant. Now, that is the only difference. I just saved you a little extra figuring there since you don't have anything to balance.

Now, that is the Panhandle field, we'll call it, and you

go ahead, step by step, and figure the remaining reserves there, just as you did in the Panhandle field precisely.

Mr. March: You haven't got enough tanks here, Mr. Keffer.

Mr. Keffer: Yes, we have.

Mr. March: You use several tanks—

The Witness: The whole point is you can't calculate the reserves of the whole Panhandle field or even part of it on that basis

By Mr. Keffer:

Q. All right, now, Mr. Hammer; then I have another field. If you don't want me to call it the Panhandle field, I'll call it some other field. I'll call it the Keffer field. I don't have one named for me, but maybe we can get one started.

Now, you have just figured the Panhandle field.

A. No, I haven't.

Q. How's that?

A. Not on your supposition I haven't figured anything.

Q. You gave us the figure you had arrived at for the Panhandle field.

A. But it wasn't arrived at by your method.

Q. All right. Now, we have this Keffer field here and you have just finished the job for the Power Commission on the Panhandle field and I have employed you to figure my field. Now, you go ahead and figure it. This is my field here and I have employed you. I want you to figure it using the same principles you used in figuring the Panhandle field.

A. I would have to have all your factual data. What is it?

Q. I just gave it to you. I had 400 pounds to start with. I have produced 15,000 feet. I have 200 pounds left. That's all you need, isn't it?

A. No, that isn't all you need in that.

Q. You can't figure it from that at all?

A. No, it isn't analogous. You recall that yesterday when we were discussing this same thing—

Q. Yes, I recall.

A. —I made the statement that in the Panhandle field that instead of one reservoir we had an infinity of reservoirs. You are talking about, and we proved yesterday in taking your three, that if you utilized just your three that you would only get 9,000 cubic feet above. Now, you go to work and add infinity of reservoirs to that and calculate it down, and as you approach infinity you will get the correct answer, but to take one reservoir and try to calculate it for the Panhandle field is absolutely impossible.

Q. All right, instead of putting one acre on that problem that I gave you, let's put 500,000 on each of them. That would be a million and a half acres and your figures on the Panhandle field is a million and some four hundred thousand odd. Let's put 500,000 acres on each one of them and then you will have that infinity, if that's what you called it there.

A. Yes.

Q. Would that make any difference?

A. You put 500,000 acres on what?

Q. On each one of those quadrants instead of just one acre.

A. You would still have your infinity of reservoirs regardless of how much you took.

Q. Sure. I got a million and a half acres and you had a million and four hundred thousand. I have more infinity than you have.

Mr. March: But you have still got three tanks, Mr. Keffer. That's right, isn't it? Do you want 500,000 tanks? We'll get down to business now.

Mr. Keffer: Just let him answer the question.

Mr. March: I am trying to clarify it.

The Witness: You have an infinite number of tanks—

By Mr. Keffer:

Q. What do you mean by an infinity of tanks?

A. Just what the word implies.

Q. I am not sure I know what it means.

A. So many that no one knows what they are, they approach infinity.

Q. I gave you a million. I gave you slightly more in acres when I gave you a million and a half acres, didn't I?

A. But that's a long ways from infinity.

Q. Well, but a million four hundred thousand is still further away from infinity, isn't it?

A. Well, yes.

Q. In other words, I am nearer infinity than you are when I gave you a million and a half acres, when your Panhandle field only had a million four hundred thousand some odd.

A. But in that extra million you had the added number of infinities on and beyond the million four hundred thousand; so all you have done is add a lot more infinitesimal spaces that didn't exist before.

Q. All right, what are those spaces?

A. Ordinarily, under any condition they would be the small reservoirs in which the gas exists.

Q. Well, I thought we had agreed way back—

A. In other words, it would be your porosity you are talking about.

Q. All right, supposing we put a little sand in these containers and create some porosity and permeability. Would you have any different answer?

A. Well, if you put some sand in this container you are talking about you couldn't have as much gas in there as you say you have.

Q. Well, take one where we will have the same amount of gas, then would that change the figure any?

A. Not as far as your reservoir is concerned because in your case you just have one.

Q. All right, now, Mr. Hammer, I didn't put any sand in that illustration to show porosity or any permeability because you said that didn't make a bit of difference on earth and you didn't figure any one of them when you were computing this acreage. Now, you have said that many times during this cross examination.

A. I said it was not necessary in the calculation. That hasn't anything to do with my statement.

Q. That's the reason I didn't put them in here.

A. I still adhere to my statement that you have an infinity of reservoirs and if you calculate by separate reservoirs as you have started out you will eventually approach the correct answer.

Q. All right, how many reservoirs did you figure in the Panhandle field when you applied your principle?

A. Actually each interval between the isobar lines for practical purposes is a separate reservoir. Now, if it had been possible and we had had maps big enough to have used one-pound isobars instead of ten, we would have very materially increased the separate tanks, you might say, that we would have utilized and we would have approached very much closer, or somewhat closer, at least, to the true figure than we now have.

Q. All right, now, Mr. Hammer, do you mean to say this: On the application of Boyle's law, that the bigger the reservoir and the greater the pressure differential the more accurate becomes the application of Boyle's law? Is that what you mean to say?

A. No, not at all.

Q. In fact, just the contrary is true, isn't it?

A. No, that is not true, either.

Q. Well, what is true, then?

A. Read that question.

(The question referred to was read by the reporter as set forth above.)

The Witness: No, that hasn't anything to do with it. Boyle's law. You can take any container, if it is large enough to calculate, and have the necessary known factors, and you can calculate Boyle's law.

By Mr. Keffer:

Q. Well, Mr. Hammer, do you mean to say that Boyle's law won't work in every instance regardless of the size of the container?

A. No, I didn't make any such implication.

Mr. Keffer: Well, read the answer that he gave. I guess I misunderstood him.

(The record referred to was read by the reporter, as set forth above.)

By Mr. Keffer:

Q. All right, do you mean to say that you have to have a big container to calculate Boyle's law?

A. That wasn't the intent of that at all.

Q. What was the intent, then?

A. Any given reservoir where you have a measured, a known pressure, and a measured volume of gas coming out, you can utilize Boyle's law.

Q. That's right, and that is precisely what we have had in every one of these illustrations, isn't it?

A. As far as a particular illustration is concerned.

Q. That's right. Does the principle ever change? Does Boyle's law become one thing on this illustration and something else on the Panhandle field or any other field?

A. Yes, as far as the field is concerned.

Q. All right, what does Boyle's law become, then, in some other field? What changes occur in the law?

A. No changes occur in the law at all. A change in the conditions—in other words, in the field. You are using one reservoir. In the field you have a multiplicity of reservoirs of different content.

Q. All right, now, do you say it works better where you have a lot of reservoirs than it does where there is just one?

A. As far as its application to the field is concerned, I wouldn't say it worked better, but we are talking about a practical thing.

Q. That's right, but where I gave you one container, where Boyle's law would have to work with one hundred per cent accuracy, as you take more and more containers and get diverse conditions in which you throw out of line, you might say, the application of Boyle's law, the more of those conditions the more accurate it becomes; now, isn't that correct?

A. Not—there would be some effect, but not where I have just stated a while ago. If we divide this thing into containers as we have, using 10-pound isobars, we are approaching awfully close.

Q. Well, you don't say that is as accurate as these illustrations as I gave here, do you?

A. I don't know of anything in actual practice in any sort of thing that is ever as accurate as a theoretical thing taken care of in a laboratory.

Q. You mean to say that the illustrations we have been working here aren't absolutely one hundred per cent accurate?

A. A theoretical thing of that type, yes.

Q. Well, practically—

A. Well, you could calculate Boyle's law there accurately by the condition you set up, certainly.

Q. You are trying to say that Boyle's law is some high-flown theory that doesn't amount to anything?

A. No, I wouldn't have used it—

Q. That's just the answer. Now, we have given you perfect conditions here for the operation of Boyle's law and it doesn't come out right, does it, as you have applied it to the Panhandle field under perfect conditions?

A. The point is, as I have repeated, you don't have one reservoir, you have a multiplicity.

Q. All right. I say, then, if we have a small reservoir anywhere, in the Panhandle field or anywhere it might be, which covered a thousand acres, you couldn't apply Boyle's law to it because you had just one reservoir?

A. Oh, yes, you could.

Q. All right, then, the fact that I used one reservoir in some of these illustrations doesn't make it any different, does it?

A. Well, it isn't pertinent to the field conditions.

Q. I think we agreed yesterday, Mr. Hammer, that when I gave you the problem that a certain portion of gas out of each of the three reservoirs that we show on Exhibit 189, that you agreed with me that the problem that I gave you was more favorable from your standpoint than the actual problem you had in the Panhandle field.

A. No, I never made any such statement. The record will show what I said.

Q. All right. The record will show this, that the variation in rock pressures on the problem that I gave you was less than actually exists in the Panhandle field. The record will show that, won't it?

A. What was that question, please?

(The question referred to was read by the reporter, as set forth above.)

The Witness: The variation in pressures?

By Mr. Keffer:

A. Yes, in your theoretical illustration, that's right.

Q. It was less. All right, and the content of the various reservoirs varied less than is actually true in the Panhandle field. In other words, you have a greater variation in the Panhandle field as to content than we had in the illustration that I gave you?

A. Yes, that is true

Q. All right. Now, that being true, if it would not work on the illustration I gave you, how on earth could it work in the Panhandle field where the diversity is much greater?

A. All right. You go ahead and add, and start with 3, and 5, and 10, and 20, and a thousand and a hundred thousand and up into the trillions or maybe quadrillions of little reservoirs and apply your problem to it and you would get the right answer, but if you want to do that, that will give you the right answer.

Q. Well, I'll let you do it.

A. I have done too much of your figuring already.

Q. All right, now, let's take just another minute or two on this. I have used three quadrants. Let us assume that this were your Panhandle field. Your three quadrants, 1, 2 and 3 in Potter County, at the same time had the same variations which I gave you in the problem which we solved yesterday and you applied that to those three areas. Do you think you get the right answer?

A. As you have used it in this illustration?

Q. Taking the basic facts which I gave you—no, not as I used it, as you used it

Mr. March: You mean taking the cylinders, too?

Mr. Keffer: Well, I don't like to just play on words. We'll call this one cylinder A, if you want to call it that; this one cylinder B, and this one cylinder C (indicating).

The Witness: All right.

By Mr. Keffer:

Q. All right, the diversity between the three cylinders as to acre content and pressures is precisely as I gave it to you in that problem; then could you apply Boyle's law to that and get anywhere nearer the right answer than you got here?

A. Very much nearer, because this is divided into a whole series of containers as outlined by your isobars.

Q. All right. What is the occasion to have the isobars at all?

A. The isobars give you your variables in well head pressures.

Q. That's right. Now, if the variation—if you constructed your isobars to where you had three groups in which they varied just as I did in the problem here, then what would be the difference?

A. Read that, please.

(The question referred to was read by the reporter, as set forth above.)

The Witness: Well, the difference is that you are trying to apply an ideal theoretical condition there when as a matter of fact that condition does not exist in actual field conditions.

By Mr. Keffer:

Q. Now, Mr. Hammer, the only reason on earth that you draw your isobar lines and weight them in as you have explained many times is to get your weighted pressure, isn't it?

A. Yes, that is right.

Q. If you didn't have to get a weighted pressure you wouldn't have to have your isobar lines, would you?

A. That's right.

Q. All right, you had your weighted pressure here to start with. I gave you that to start with, didn't I, in the problem we have been working?

A. That's right.

Q. There would be no occasion to draw any isobar lines on this because you have your weighted average to start with.

A. That's right, in your picture.

Q. Then why talk about your isobar lines, because if you drew isobar lines the only thing you would be working to would be the very thing that you started with?

A. That's true as far as your cylinder is concerned, but it doesn't apply to the field condition.

Q. Now, Mr. Hammer, as a matter of fact, your pressure decline method will work properly, if the pressures of your field were uniform, won't it?

A. It will work properly under conditions under which it has been working.

Q. Well, answer my question.

A. If you had ideal conditions, yes.

Q. If you shut the Panhandle field in and let the pressures equalize and then apply your Boyle's law, then you get the right answer, approximately, wouldn't you?

A. You would get a close answer, yes. You would probably get the best answer, I will say that.

Q. Or if the entire field was of equal productivity, every portion of it, and every area of it and you applied Boyle's law you would get the right answer, wouldn't you?

A. That is not necessary.

Q. Wouldn't you get the right answer?

A. If you had that condition.

Q. But neither one of those conditions exists in the Panhandle field, do they?

A. That is true.

The witness was then referred to some figures in Exhibit 182 which were compiled by Commission Witness Stevens, and he stated that the pressure decline, as determined by Stevens on an arithmetical average of wells as to the quadrants in which Canadian River owned acreage, was 15.6 pounds from midyear 1938 to midyear 1939, and on this basis the life expectancy of the Canadian River reserves would last for 21.3 years from August 1, 1939, to a 25 pound abandonment pressure. He stated, however, that this exhibit was predicated upon the volume of gas that each well would produce, and it was his opinion that the present wells would not produce the entire volume of gas now in place.

Gas will migrate more rapidly under similar conditions as to permeability at high pressure differentials than it will at low pressure differentials. The witness was then asked if it wouldn't be possible for gas to migrate more rapidly with low pressure differentials where the permeability was high than it would in the case of high pressure differentials where the permeability was low. He stated that the question of infinity of conditions again comes into play, and it is a difficult question to answer for that reason, but that it is possible to have a situation where the formation is so permeable that gas will migrate from one part

to the other with practically no pressure differential. Gas will migrate more rapidly through a 50% permeable formation with a 10-pound pressure differential than it will through a 10% permeable formation and a 10-pound pressure differential.

The witness stated that the lowest pressures in the Texas Panhandle Field exist along the northeast side of the field and that this is due to heavy gas withdrawals in that area. There is no particular water drive in the Texas Panhandle Gas Field.

The area around Borger and Sanford, in Hutchinson County, which is in Quadrants 2 and 3 in Hutchinson County, presents a situation where the pressures have remained approximately stationary over the five-year period studied by the witness. However, the average for Quadrant 3 shows a decline by reason of the fact that it extends northward into a high pressure area in which pressures are declining.

If an area is increasing in pressure while it is producing substantial volumes of gas, the only logical conclusion to make is that such area is receiving gas from other areas by drainage, and the same thing is true for areas where the pressure is declining but where the decline in pressure is not as rapid as related to the total amount of production as was true in the earlier producing history of the wells. In other words, this would indicate either drainage into the area or water encroachment which was reducing the size of the reservoir, but the witness stated that, in his opinion there is no water encroachment in the Texas Panhandle Gas Field. If there was, Boyle's Law could not be applied at all, and if there was just a little water encroachment or water drive this would throw you off to some extent in the application of Boyle's Law.

The witness did not know that after the carbon black law was passed, that is, the law which permitted sour gas to be utilized in the manufacture of carbon black, there was a very definite increase in the production of sour gas in Moore County. The witness, however, has not compared sour gas with sweet gas production on a reserve basis and does not know the difference in the sour gas portion of the field and the sweet gas portion of the field. His map,

however, does show the approximate division line between the two portions of the field. The witness was not interested either in the area with respect to sweet or sour gas.

The witness stated that if the sour gas area did not contain more than one-half of the acreage of the sweet gas area, and the production in the two areas was about the same, this would in time affect the sweet gas area and would in time have a tendency to set up a low pressure area in the sour gas area; that if production in northern Moore County continued at a higher rate than the production in the sweet gas area this would have a tendency necessarily to cause a migration of gas from the sweet gas area to the sour gas area. When the pressure differentials are set up this will have a tendency to cause the sweet gas to drain into the sour gas area.

The area just north of the Canadian River leases in Moore County has had a very intensive development. The extent of development of Canadian River's acreage has been about one well to 2,300 acres, while just to the north of the Canadian River acreage and adjacent, the development has been on the basis of about one well to every 640 acres.

Witness called attention to the fact that in an area embraced in Quadrant 1, Moore County, and Quadrant 3, Hutchinson County, Canadian River Gas Company has 30% of all of its wells located on 14% of its acreage, and for this reason he felt the Company was situated so as to amply protect itself from drainage. Witness also called attention to the fact that the Company proposed to drill some additional wells in this area.

The witness stated that notwithstanding the above, it still appeared that the pressures were higher on the Canadian River Wells in that area than were the pressures on the offsetting wells, and that notwithstanding the heavy production of Canadian River Gas Company in the area referred to, they were still unable to reduce the pressures on their leases sufficiently to prevent some drainage of gas away from their acreage to the north and northeast. The witness did insist, however, that this was a question of degree, but unquestionably there is drainage there. He didn't know how much, but it was his impression that it was not long distance or mass drainage, although he didn't know.

The witness further testified (Vol. 58, pp. 8178-8182) as follows:

Q. That's right. Even with those large number of wells that you speak of, of Canadian River Gas Company, located near the outside limits of their reserve, still the pressure on Canadian River wells in that very area you refer to is higher than the pressure on the offsetting wells to Canadian River reserve. Now, isn't that a fact?

A. Well, I would have to check.

Q. Let's check it right now. Here it is right here (indicating).

A. You mean isobars?

Q. Well—

A. I think the way to answer that is that the pressure according to this isobaric map in general is slightly lower to the north of your acreage.

Q. And to the northeast?

A. Yes, that is true as far as the map is concerned.

Q. All right. Notwithstanding the heavy production of Canadian River in the areas which you spoke of, they are still unable to reduce the pressures on their leases so as to prevent drainage of gas to the north and to the northeast? That is absolutely correct, not just approximately, isn't it?

A. Well, it is a question of degree.

Q. That wasn't my question.

A. Well, now, wait a minute.

Q. All right.

A. I'll answer your question. I said it is a question of degree and yet unquestionably there is some migration, but it is a question of degree of migration.

Q. That's right, you don't know how much?

A. No.

Q. You know there is some?

A. Yes.

Q. You know as a matter of fact that Canadian River, concentrating their production as they have in the area which you say they have, that if they were successful in preventing migration you wouldn't have the isobar lines stepping down ten pounds just consecutively one after the other toward the low pressure area, would you?

A. Well, unquestionably there is drainage there, but

it is my impression that it is not long distance or mass drainage.

Q. Just a minute. You said you didn't know.

A. I said it was my impression. You can have an impression without knowing.

Q. You still don't know, is that right?

A. I don't know anything about the volume and I don't believe anyone else does.

Q. Now, you don't want the Examiner to take your impressions on this, do you?

A. If you insist, Mr. Keffer, I will say that it is my opinion that there isn't any way to prove—

Q. Just how much drainage?

A. That's right.

Q. All right. Well, I think that's good enough. All right, now, you do know this, Mr. Hammer, that there is a great deal more gas per acre being produced adjacent to and just beyond Canadian River acreage in Quadrant 1, Moore County; Quadrant 2, Moore County; Quadrant 3, Hutchinson County, and Quadrant 4, Carson County, than is being produced from Canadian River acreage per acre, don't you?

A. Well, no, I don't know that.

Q. Well, didn't you check that?

A. I didn't segregate to find out. I wasn't interested in what the individual operators were producing.

Q. In other words, you weren't interested in whether we were suffering drainage or not, is that your position?

A. All I was after, Mr. Keffer, were the reserves of gas in place underneath your acreage as of a certain date.

Q. As of a certain date, regardless of drainage in or out?

A. Well, I said, as of a certain date.

Q. Well, that's all right. All right, now, the average weighted rock pressure of Canadian River acreage is much higher than it is for the field as a whole, you do know that? You had to find that out, didn't you?

A. Yes, I think that is correct.

Q. And greater than it is in the surrounding acres to the northeast and northwest?

A. Right.

Q. We are also agreed that gas migrates from high pressure areas to low pressure areas so that migration would necessarily have to come from whose land?

A. Well, you have got to go a step further.

Q. Sir?

A. You must go a step further to get a true picture. It is also true that there is a high pressure area to the north of this intensive area you are talking about, and gas, if it is coming at all, it is also coming in from the north.

Q. Into Canadian River?

A. No, into this low pressure area you are talking about.

Q. It may be coming both ways.

A. That is right.

Q. In fact, your map shows it certainly is coming from Canadian River.

A. Well, it also shows that it is coming in from the other direction.

Q. I don't know that I am prepared to agree with you. Regardless of that, I am talking of Canadian River. It shows definitely that it is flowing from Canadian River into that area.

A. But to paint a true picture, you have to have both sides of the picture.

Q. Not to show that we are losing gas. The fact that we are losing gas doesn't give us much consolation if Mr. Lange is also losing gas. We are still in a bad way, isn't that right?

A. That is true.

The witness then stated that although in his direct examination he had used the expression that the Canadian River reserves would last 73 years, this was intended simply as a statement of what would happen if conditions remained just as they are at this time.

Witness HAMMER further testified (Vol. 58, p. 8187) as follows:

Q. All right, but this graph that you are talking about is consistent with your 73-year estimate, isn't it?

Mr. March: We object to that question—

The Witness: No, it is not.

By Mr. Keffer:

Q. I thought it was.

A. No, it isn't at all.

* * * * *

The witness further testified (Vol. 58, pp. 8190-8210) as follows:

By Mr. Keffer:

Q. Mr. Hammer, just as we recessed for the noon hour we were discussing I believe your Exhibit 180.

A. I believe that's right.

Q. Now, the three small points on that—Page 4B—

A. 4B?

Q. Yes, sir. The first point on that which represents approximately 425 pounds pressure, as I read it—

A. Slightly less than that.

Q. Not very much—do you know what it does represent?

A. I can tell you in a minute. It represents 422.7 pounds.

Q. 422.7. Now, what is that figure and where did you get it?

A. That is the weighted areal average pressure for the group of quadrants used in the determination of the factor 35.01 production per acre pound decline for application to Quadrant, Potter 3.

Q. Now, Quadrant 3, Potter County, I believe the record shows commenced production a long time before 1935, didn't it? This pressure was the pressure for 1935 as I take it.

A. That's right. Yes, this figure is 1935, that's right.

Q. Now, Quadrant 3, Potter County, came into production a long time before 1935, didn't it?

A. Well, I presume it did because there had been some production taken out.

Q. There had been some pressure drop?

A. Yes, there had been some pressure drop in that area.

Q. I will ask you if it had not come into production as early as 1928 or 1929.

A. I wouldn't know, Mr. Keffer, exactly.

Q. You didn't check as to that?

A. No, I didn't.

Q. Now, if it did come into production as much as six years earlier than what your line shows there, you would have virtually a straight line back from the line you do have for six periods, wouldn't you?

A. Read that question.

(The question referred to was read by the reporter, as set forth above.)

The Witness: Back to what year—1929?

By Mr. Keffer:

Q. 1929, that is what it would run to, yes.

A. Yes, I think that is true.

Q. All right, then, your curve, if you plotted that on your curves you show on Page 4B of your Exhibit 180, then you would have practically a straight line back to the left for as long a line as you have a dropping line to the right, wouldn't you?

A. Well, you know, as I said this morning, the actual question of time isn't the controlling factor in this. The controlling factor is the volume of gas removed.

Q. I appreciate that.

A. Regardless of time.

Q. But if you wanted to get an absolutely correct line, a graph from the time that quadrant came into production, you would for a period of five years have almost a straight line. It would be dropping a little bit, but not very much, until you got up to 1935, then it would be dropping more. You would have a line coming over sort of like that (illustrating), wouldn't you?

A. No, I don't think so.

Q. Why, it is so obvious, Mr. Hammer, I wish you would explain to me why you wouldn't have.

A. Well, you would have a straight line.

Q. Sir?

A. You would have a straight line.

Q. That is, a horizontal line, practically—not quit, but almost?

A. Horizontal?

Q. Yes.

A. No.

Q. It would be much more horizontal than the one you have plotted here.

A. No, I don't think that is true.

Q. In the same period, a five-year period, you go from 422 something—is that what you had?

A. Yes.

Q. —down to right at 400. You went down 22 points there; didn't you—a little more?

A. Yes, 402.8.

Q. According to your graph.

A. Yes.

Q. Then if you extended that graph on back to the time when the quadrant came into production, over a six-year period, you would have dropped only about seven pounds, wouldn't you?

A. Well, that just brings out the point I was talking about. Time doesn't enter into it.

Q. You would have had, wouldn't you—

A. Yes, if you do that, but time doesn't enter into it. It is the volume of gas taken out, regardless of time.

Q. What was the volume of gas taken out prior to 1935?

A. I don't know.

Q. It could have been a big volume so far as you know.

A. Yes, it could have been.

Q. That's right. Then if you were wanting to give absolutely an accurate picture you would have started back at the beginning instead of in the middle, wouldn't you?

A. No, not necessarily.

Q. You say the longer the period the more accurate your calculation, yet you didn't take as long a period as you could have taken.

A. I will say this, that if the data had been of such character that you could have utilized it with any degree of accuracy—

Q. What was wrong with the data in Quadrant 3, Potter County?

Mr. March: Let the witness finish.

Mr. Keffer: I think he had.

Mr. March: No, he was right in the middle.

The Witness: —that is just one of the several quadrants you utilized to arrive at the total reserve for Canadian River acreage.

By Mr. Keffer:

Q. Oh, I appreciate that. The question I asked you was what was wrong with the data on Quadrant 3. Please answer that simple question.

A. Well, it would be impossible to take one quadrant and go clear back when you couldn't get the data on all the rest of them.

Q. I know, Mr. Hammer, but if you will just answer my question we can get along much faster.

A. What was his question?

The Trial Examiner: What was wrong with the data on Quadrant 3, Moore County.

Mr. Keffer: No, Potter County.

The Witness: Well, the point is that we had a great group of acreage here. Now, if you couldn't get data back to the same point on all of them that were dependable it would have been useless to take it on one or two that might be dependable.

By Mr. Keffer:

Q. But you still haven't answered my question, Mr. Hammer.

A. Read the question.

(The question referred to was read by the reporter as set forth above.)

Mr. March: He has told you that. I want to bring it out in the record. He stated that his answer to that is that he couldn't get the data on all the rest of the quadrants, therefore, there wouldn't be any use, it would be impractical to take Quadrant 3 alone.

Mr. Spencer: You answered it just the same way he did, and just as well.

Mr. March: Thank you.

The Trial Examiner: The question pertains to the data in the particular quadrant, Mr. Hammer.

The Witness: Well, I don't have all of the data on Quadrant 3 back to the beginning as a separate quadrant. I only utilized that for the same period of time that we were forced to use all the rest of it. It might have been good. I think perhaps it was, but as I stated, it you couldn't get good data on all the areas that you could rely on it wouldn't do any good to take all the data on one of them.

By Mr. Keffer:

Q. Well, then, your answer is, I take it, that there was nothing wrong with the data on Quadrant 3 so far as you know?

A. So far as I know that is right.

Q. You have no reason to suspect that there was anything wrong with it?

A. That is right, as far as I know.

Q. All right. Now, that is the only quadrant you show, isn't it?

A. That's right.

Q. Now, you didn't go back to the beginning of production, then, on a single quadrant in which Canadian River Gas Company has acreage, did you?

A. You mean to the beginning of the life?

Q. That's right, the beginning of production.

A. No.

Q. Well, why didn't you do it?

A. I have just explained why I didn't do it.

Q. All right, was there anything wrong with the data on any of the Canadian River quadrants?

A. Well, I think Mr. Spencer will recall that there were a great many letters written to him during 1939 asking for this and that and the other thing. I feel relatively sure that after the work that we did in collecting data from the Railroad Commission in Texas plus the information we got from Mr. Spencer, I believe that we got a fairly accurate picture of the gas that came from all of the Canadian River acreage. I think we did.

Q. All right, the only picture you got is the different periods, the different markets, the different pressure bases that were used, isn't that the net result of it?

A. What was that question?

(The question referred to was read by the reporter as set forth above.)

The Witness: Well, I don't have all that data, but I do know that we got certain data from him and I do know that he told us in a letter that as near as he could give it to us that certain gas, and I believe he went to work and tied it down to particular wells as far as he could—as I re-

call it, he told us that the gas had been metered at four—I believe it was—four different pressure bases.

By Mr. Keffer:

Q. And gave you what those bases were?

A. That's right.

Q. Then, so far, at least, as Canadian River acreage is concerned you could have gone back to the beginning of production?

A. Yes, I could have done that.

Q. But you didn't do that because you couldn't do it for the field as a whole?

A. Not for the field as a whole but even in the areas where Canadian River has its acreage I couldn't do it.

Q. You couldn't have done it?

A. No.

Q. Which quadrant are you speaking about?

A. Well, I would say Quadrant 1, Moore County—

Q. All right, what was wrong with Quadrant 1, Moore County?

A. —and Quadrant 3 in Hutchinson County, and as I remember it, Quadrant 4 in Carson County.

Q. What was wrong with Quadrant 1 in Moore County?

A. Well, there have been a lot of wells drilled in there prior to 1935.

Q. Who drilled them?

A. Well, if I had time enough I could tell you who drilled them, but I think Canadian River drilled part of them.

Q. That's right, and you had all the information on them and—

A. Yes, I think that is right, on the Canadian River wells.

Q. Texoma drilled a few prior to 1935. You had the information on those, didn't you?

A. Yes, I think that is right.

Q. Wasn't that about all that was drilled before 1935 in that quadrant?

A. I would have to check. I don't remember.

Q. Well, would you say you could have gotten good information on Quadrant 1, Moore County, back to the beginning?

A. I wouldn't want to say. It is my remembrance—

Q. You just made no effort to determine, is that right?

A. Well, the whole point is that in the areas embraced in that part of the field where the Canadian River has its acreage there was so many records that weren't dependable that we just felt it was not—well, it was impossible to rely on them.

Q. All right, then, we'll go from that. This method of least squares that you have been utilizing, you could have a curve that goes up and down and up and down and up and down, peaks and valleys in it, and you could still straighten it out by that method, couldn't you?

A. That's right.

Q. If you had a curve that made an arc sort of like a half-dollar, the outer edges of it, you could straighten one of those out, couldn't you?

A. I never had occasion to apply it to a hyperbolic curve, no.

Q. It would work, wouldn't it?

A. I have never used that way. I suppose it might.

Q. In fact, it doesn't make any difference what kind of curve you have, you can always straighten them out by applying this least squares theory?

A. Well, I wouldn't want to go so far as to make a general statement of that kind.

Q. Where did you get that theory, Mr. Hammer?

A. Well, I knew that—I have known for a good many years that the method was applied to the projection of certain curves by—oh, statisticians and by certain chemical formula and general things of that type where the points did not—through which they wanted to draw a curve that did not fall in exactly a straight line and it has been utilized for that purpose.

Q. Well, I have seen lots of lines for long periods of time that weren't straight and I am wondering if this line ought to be straight, if in straightening it out you stayed with the tools which nature had given you up there to work out this problem.

A. Why, certainly it ought to be straight.

Q. How's that?

A. Certainly it ought to be straight.

Q. Ought to be?

A. Certainly.

Q. Why ought it to be straight?

A. Well, that is absolutely according to the principle of the Boyle's law. If you take out so much gas and you calculate your thing properly, why, you will get a straight line projection.

Q. Yet we didn't get it here, did we?

A. Oh, yes, we did.

Q. No, when you applied Boyle's law you didn't get a straight line. That's just what I'm talking about. You had to go to something else to get your straight line.

A. No, I didn't.

Q. All right, if you apply Boyle's law and plot your points there which you have, it wouldn't be the kind of a line you have got, would it?

A. Yes.

Q. Look on your map—on your graph and see if it would.

A. All right, which graph?

Q. The one on page 4B.

A. Yes, you would have a straight line.

Q. What makes it straight? If you are drawing from the center of one point to the center of another, do you have a straight line?

A. Oh, well, what we are doing is drawing a weighted curve through points of different values.

Q. Right. You weighted everything you can on your method of weighting, applied Boyle's law to it and didn't get a straight line; then you went to this least squares and you straightened out Mr. Boyle's line. Now, isn't that just what you did?

A. No, that is not a true statement of it at all.

Q. Well, I wish you would state it absolutely as you did it.

A. We utilized the five years of weighted pressure decline and production and for each year of the five years that was calculated and the curve represents, not one year or not a point from one year to two years, but a weighted curve for all of the years. That's what your production per acre pound decline is based on, not one year.

Q. I understand very well, Mr. Hammer. Now, let's go back to 4B, to the curve which you have extended out there across your paper three times. Isn't that the curve that Boyle's law gave you as you applied it?

A. Yes, it is.

Q. Well, let's look at it.

A. All right.

Q. Here on Page 4B, if you drew a line from the center of your first point to the center of the second point, which you didn't do, it would drop down from the way you have it, isn't that right?

A. Yes, but it wouldn't mean anything.

Q. You just answer my question.

A. I said yes.

Q. Then you draw a straight line from the middle of that point to the middle of the next one and it would be slightly below where you have it there?

A. That is true.

Q. Then you draw a straight line from that point to the next point and it would end up slightly above where you have your line, wouldn't it?

A. That is also true.

Q. And if you draw from there to the next one it would be slightly below?

A. That is also true.

Q. That is the curve of the line you got from applying Boyle's law?

A. No.

Q. How did you get it?

A. The line we got from applying Boyle's law is the line upon which these larger points are projected.

Q. Where did you get the line as we have reconstrued it, drawing it from the center of one point to the next? Where did you get that line?

A. I didn't get any line drawing from the center of one point to the other.

Q. If you had plotted it accurately that is the point you would have gotten?

A. It is not, or any other method under Boyle's law, where you are weighting out several years.

Q. Look here, Mr. Hammer. You have a pressure drop It takes you down to this point here, starting here (indicating), and you draw a straight line across there and you have a pressure that takes you down like that and you plotted it in and it comes out like that and you plot it in and comes down like that and you plot it in. Can you see that line? (Indicating in Exhibit 179.)

A. I can see it approximately.

Q. That is precisely what you get when you take the data which you have and plot it on a curve, isn't it?

A. That is the curve you get when you plot your pressures against your accumulated production.

Q. All right, isn't that what you are doing here?

A. Yes, but all of the things you are talking about have been weighted in and in a determination—

Q. As you have described it heretofore, in getting your points to construct this irregular line you have indicated there?

A. I had all the data, yes, and utilized it.

Q. And you did all of your weighting then, too, didn't you?

A. When I arrived at the production per acre pound decline.

Q. That is right, you had all that, didn't you?

A. It is all weighted in.

Q. And you had that when you reconstructed this irregular line, didn't you?

A. (Pause).

Q. Will you answer my question?

A. I had all the data, naturally, from the beginning.

Q. It has been suggested that you might not understand my question.

If you are plotting it by year like the one we are talking about—the one we were talking about was in your Exhibit 180—

A. If you plotted your accumulated production against—

Mr. Spencer: By years—

The Witness: —your pressure decline.

By Mr. Keffer:

Q. That is right, year by year.

A. Or any period. It just happens that year to year was used.

Q. When you did that you had an irregular line instead of a straight line?

A. Certainly.

Q. Well, I guess we are talking about different things.

When you make that irregular line a straight line, how do you do that?

A. That is where we utilized this simultaneous equation as shown on Page 3.

Q. Sir?

A. That is where we utilized this simultaneous equation shown on Page 3, Exhibit 180.

Q. How many other fields have you used that simultaneous equation on, Mr. Hammer?

A. I haven't used it on any others.

Q. I see. Do you know any other field—strike that.

It is the first time you have ever tried it?

A. Well, it is the first time I have ever tried it for a particular case like this.

Q. And you haven't any experience to know whether it is going to pan out or not; you are going to have to wait until the field is exhausted before we can tell, is that right?

A. No. It has already been proven. The curve right here (indicating) proves it.

Q. You have a straight line. You will have to get a straight line when you apply that formula, no matter how crooked it was?

A. Yes, and it checks in with your accumulated production as against your pressure decline. What better proof do you want?

Q. How do you mean it checks?

A. It draws the best possible curve that you could get through those five divergent points.

Q. Do you have the charts on the other quadrants you made your basic line from?

A. It wasn't necessary to make one. I just made one by point of illustration. When you get your production per acre pound that is equivalent to a curve.

Q. Well, as I recall, when we got our production per acre pound on various quadrants every time we had a different grouping we got a different figure.

A. Well, when we grouped different acreages and the factors contained in those different acres, why, naturally we would get a different figure.

Q. But not from the particular quadrant? The gas didn't change in place under that quadrant, did it, just

because you made a different grouping of some other quadrant?

A. No.

Q. The gas didn't know you did that?

A. But the weighted pressure—I thought I explained that sufficiently. Just take your Quadrant 3 here—

Q. Sir?

A. The whole idea—I think it is sound—I think it is sensible and I think it is fair—is to take instead of one quadrant alone where there is indication of the movement of gas either to or from a five-year period—the quadrant upon which you want to make your determination in those adjacent quadrants, and from a group arrive at a production per acre pound.

Q. Yes, I know that.

A. It can then be applied to the quadrant in question.

Q. All right. Now, you have drawn a line on Quadrant 3, Potter County, and you have drawn a master line for all of the quadrants in which Canadian River acreage is located, based upon Quadrant 3, Potter County, is that right?

A. No.

Q. Why did you show Quadrant 3 in Potter County?

A. I have just finished explaining that every time you make a calculation for production per acre pound decline it is equivalent to drawing a curve.

Q. Suppose it wasn't per acre pound decline, just a decline of so many pounds per so many billion feet of production, what is the difference?

A. There is a lot of difference.

Q. Tell me the difference.

A. What?

Q. Tell me the difference.

A. Well, this whole thing is a weighted proposition. You have to weight it against your acreage and you have to weight it against your pressure decline and in doing that we had to construct these isobars in order to get the proper weighting. Now, those factors are all weighted in. You can't just grab a lump figure out of the air and utilize the same principle.

Q. When you get your acre pounds that is just a matter of weighting your basic segments, isn't it?

A. When you get your isobar segments?

Q. That is all you do?
A. That is right.
Q. And that is all there is to it?
A. As far as the acre pound is concerned.
Q. That is right, as far as the acre pound is concerned. If you took your isobar lines or segments all the way across the field as you have drawn them here and get a weighted average pressure for the fields, you would have the same thing, wouldn't you, expressed in a different manner?
A. Yes, that is the basis upon which I gave you those weighted pressures.

The witness stated that you could calculate production per acre pound for the entire field in the same manner that he calculated production per acre pound for each local area (quadrant), and that if one wanted a picture of what was actually happening in the field he could plot the weighted pressures as against production for each yearly period, and this would show what the field was doing with respect to decline in rock pressure as related to production.

He stated the picture would probably be accurate, but it wouldn't be practicable to apply the results to any local area in the field, but still it would be accurate in so far as the application of Boyle's Law to the field-wide picture is concerned.

The witness further testified (Vol. 58, pp. 8212-8213) as follows:

Q. I mean when you plot your pressure drops against production you don't have a straight line?
A. As I have said before, and I think your own men will agree with me, they have seen, literally speaking, probably hundreds of curves plotted, each on individual wells, and there is always variation, more or less. If they plotted the curves themselves they would try to plot that mainly so it would go through those points and give the best straight line.
Q. But when you are extending it, giving the best straight line, that is when you are using your own judgment?
A. No, you are not. You are projecting into that in the future as to the history it has shown in the past.
Q. Suppose you had used your last two points on plotting your straight line on Page 4B, it would have been slightly a different line, would it not?

A. Page 4B?

Q. Yes.

A. Yes, and if you had used your 1937 and 1938 you would have had another line.

Q. And if you had used the 1935 and 1936 you would have still had another one?

A. There is no argument on that.

Witness had left out Wheeler County Quadrant 1 in determining his weighted average pressures, and gave as his reason the following:

> "Certainly if I had reason to believe, or if any other engineer happened to believe that a certain area, although some railroad commission or somebody might have included it in an area, that that particular area was not productive and had no value, I think you would be wrong in including it. That is my position on it."

Witness stated that if Boyle's Law were working perfectly you could not take any year, or any other period, and get the same results because the data might vary from time to time but that if you had accurate information the results would check. For example, the estimate would be the same if the data for the period from 1935 to 1936 only were considered, or from 1938 to 1939, or any other yearly period, if the data was perfect and if you had absolutely ideal conditions. The witness means by an ideal condition —an experimental application of Boyle's Law, such as a laboratory experiment.

Again referring to the original of Wheeler County Quarant 1 in his estimate of field reserves, the witness stated that he had not utilized it because there was no recorded production that the railroad commission had during the five-year period he considered. It was then called to his attention that his work sheet showed that during that period there had been produced from this quadrant 523,042,000 cubic feet. Witness insisted, however, that even so, this was not much gas and still insisted that the quadrant was largely exhausted of its gas. He was then asked if his computations on the Wheeler County Quadrant 1 did not give an acre pound factor of 30.24, and he could not recall whether it did or not, but that the figure of 30.24

was reached by him by the application of the least squares theory and subject to check.

The witness further testified with respect to Wheeler County Quadrant 1 (Vol. 58, pp. 8233-8236) as follows:

A. But when we found out that the area looked like it was depleted as far as any oil or gas was concerned, and particularly as far as gas was concerned, there was no reason for utilizing and figuring the future reserves if there wasn't any gas left there. I mean, of course, you might drill a well and get a show of gas, or a small well, but for all practical purposes we considered it a depleted area.

Q. All right, but you got this 30.24 by the application of this least squares theory, didn't you, when you worked it out?

A. Yes.

Q. And that gave you an original acre content of better than 13 million feet per acre, didn't it?

A. I would have to check that. I don't recall that.

Q. And that is the reason you threw it out?

A. That is not true.

Q. You knew that answer you got was out of all proportion than from what the physical conditions showed as being there; you threw it out definitely because your system wouldn't work and you didn't want it to come out in this case?

A. That is not a true statement.

Q. Give a true statement.

A. I have already given it.

Q. All right. When you applied your pressure decline method in the least squares, Quadrant 1, Wheeler County, as you applied it to the field you got an acre content of 13 million cubic feet per acre; that is right?

A. I say it is right, subject to check.

Q. You knew there was a field that was depleted and you had five hundred million cubic feet in figures, a difference of 26 to 1, and you knew you couldn't come into this case with a discrepancy such as that?

A. Well, that statement that you are making is absolutely untrue.

Q. You did have that discrepancy?

A. I have stated that we found out that the area was depleted and we decided not to use it. I stand on that.

Q. All right, it did show 13 million feet per acre, as you computed it?

A. I don't recall.

Q. Will you check your working papers?

A. Yes, I will check them.

Q. You knew it didn't have anything like that, didn't you?

A. Well, I don't remember whether it was that or whether it was something else. I want to check that whole situation.

Q. You have stated many times it was worthless; therefore, you didn't include it?

A. I think you are in erorr as far as that 13 million cubic feet is concerned.

Q. You can check that to see if I am in error.

A. Yes, I will check it.

Q. Now, if you made some particular effort on the field-wide figures to have gone back to the beginning of production, you would have had a lot larger volume of gas to have considered and a lot larger producing history to have considered, wouldn't you, Mr. Hammer?

A. That is true, if it had been possible to get it.

Q. But even with some diligent work you could have gotten pretty accurate figures on that?

A. I doubt it very seriously.

Q. You didn't try?

A. I asked a lot of questions—

Q. But you really didn't get down and try to get the figures, did you?

A. When folks like Phillips Petroleum Company who have been in there from the beginning and who had probably more scouts in the field than anybody else and had made an effort to keep a record of all of the wasted gas and all of that sort of thing, will tell you that they are not sure of their estimates, I would like to know how anyone else could do it with any degree of accuracy.

Q. Can you ever be sure of an estimate?

A. You never can be sure on estimates of that type.

Q. You have made an estimate of the field here, haven't you?

A. Yes, on data and records.

Q. You are not sure of it?

A. Yes, I am relatively sure.

Q. I thought we agreed several times that no one could be certain about that.

A. Of course, there is never one thousand per cent accuracy. Your men don't have one thousand per cent accuracy.

Q. I will grant you that.

Since we can't be certain about any of these things, it is obvious we should be as certain as we can?

A. That is right.

The witness further testified (Vol. 58, pp. 8241-8246) as follows:

Q. Mr. Hammer, just another question on your Wheeler County Quadrant 1. You gave us one of the reasons why you didn't use the production history, and you had a production from that quadrant of 523,000,000 cubic feet of gas. Now, I will ask you if you have other quadrants in the field in which you had less production even than that and which you did use.

A. I couldn't answer that from memory.

Q. Let me ask you this and you can check it: Didn't you have from Gray County 1, a production of 80,513,000 feet? Look at your papers and see if you didn't.

A. I don't have that statement for the whole field. I don't have it here.

Q. Don't your papers there show that? Don't you have that in your working papers? You don't have a single thing which you can check that with? It would be a most obvious figure. You ought to have something there, because that is the thing you had to have as the very basis of your calculations. Did you look in your suitcase—your briefcase to see if you don't have that? Do you have your working papers?

A. I have looked and I don't have my working papers here in the hearing room, not on the total field. I assumed that you were through with those. I didn't want to load this thing down and I took some of this out.

Q. Well, will you check that and see if that isn't a correct statement, and in Gray County, Quadrant 2, you had production up to August 1, 1939 of 240,300 cubic feet—Mcf. That's 240,300,000 cubic feet.

A. What were those?

Q. The previous one was 80,513,000 cubic feet, not Mcf.

A. What quadrant was it you wanted checked?

Q. Quadrants 1 and 2, Gray County.

A. Quadrants 1 and 2, Gray County, and what else?

Q. Well, let me check that—yes, that's what it shows.

A. Just those two quadrants, 1 and 2—1 and 5, Gray?

Q. That's right—well, you got those for 1 and 2, haven't you, Gray County?

A. Yes.

Q. And your figures to verify?

A. 1 and 2, yes, that's right.

Q. That's right.

A. Those are the two you want?

Q. That's right. You might verify the figure we gave you on Wheeler County which is taken from your working papers. That's Wheeler County 1.

The Trial Examiner: What was that figure, Mr. Keffer?

Mr. Keffer: That figure was 523,042,000 cubic feet.

The Witness: All right, I'll check that one.

By Mr. Keffer:

Q. Now, Mr. Hammer, I asked you the other day if your figuring this field by quadrants didn't give you a bigger figure—a bigger reserve than you would have gotten if you had figured the field as a whole and you said you didn't know.

A. No, I don't think I said I didn't know. I said my remembrance—my remembrance is that I said that I thought that the calculation of the field by the quadrant system would give me a more accurate result than if I tried to do it by the whole area.

Q. I know, but the question I asked you was if it didn't give you a higher result and that is what you weren't certain about.

The Trial Examiner: Mr. Keffer, when that came up yesterday, wasn't it decided to let Mr. Hammer see if he couldn't find that figure in his working papers?

Mr. Keffer: I believe it was. Mr. Hammer hasn't given us a figure, however, the other figures which he has given us this morning I think will demonstrate that figure.

The Trial Examiner: I believe you brought that up yesterday.

Mr. Keffer: That's right, either yesterday or the day before.

The Witness: It was my understanding that I have given you all that you asked for. If I overlooked something, it wasn't intentional.

Mr. Keffer: I think we have it with what you have given us. I think the figure will work out.

Q. Now, you gave your weighted pressures this morning at the various years. Those figures were 369.25 pounds for August 1, 1935.

A. That's right.

Q. That is correct; then at August 1, 1936 it was 360.74 pounds.

A. That is correct.

Q. At August 1, 1937, 352.02 pounds.

A. 352.02.

Q. August 1, 1938, 343.01 pounds.

A. Right.

Q. August 1, 1939, 332.98 pounds.

A. That's right.

Q. All right, now, if—relating that back to your production figures for each year, Mr. Hammer, you had the period 1935 to 1936, 620,404,940 Mcf., did you not?

A. No—you mean from August 1935 to August 1936?

Q. Yes.

A. Well, the figure there is 615,778,940.

Q. Oh, yes, I see the difference. If you included Wheeler County 1, you would have had 620,404,940. You would have five million more there.

A. I hadn't made the addition. I assume if you added that five that it would give you something like that.

Q. But the figure you did give was 615,778,940 Mcf.

A. That's right.

Q. And you had a pressure decline that year, that is, from 1935 to 1936, on your pressures as you have figured them of 9.24 pounds.

A. No, it is 8.51 pounds.

Q. All right. I have the figures with the Wheeler County quadrant in. That's where we are off. I thought the adjustment had been made here, but it has not. Just one second and we'll take those figures with the Wheeler County quadrant out.

Mr. Keffer: I believe, Mr. Examiner—Ithought we were in position to go into the matter, that the matter had been computed and the figures worked out, but with Wheeler County quadrant left out, but those figures are in. In the figures that were presented this morning the Wheeler County quadrant was left out and it has thrown our figures a little bit haywire and it is going to take a little time to figure the matter and that being true, and, further, the fact that the large sheet that was handed Mr. Hammer yesterday for verification has not yet been verified.

Mr. March: We'll stipulate that it is correct.

Mr. Keffer: How's that?

Mr. March: We'll stipulate for the record that that is correct.

Mr. Keffer: That sheet is?

Mr. March: Yes.

Mr. Keffer: All right, that's fine.

Mr. March: We haven't checked it, but we will stipulate that it is correct.

Mr. Keffer: That's right, we do get back to the Wheeler County matter again.

Witness HAMMER further testified on cross examination, Vol. 59, pp. 8298-8466, inclusive, and particularly pp. 8309-8359, as follows:

Q. Mr. Hammer, I asked you yesterday for another computation for the production figures on Gray County, Quadrants 1 and 2. You said that you couldn't give me that at that time but that you would get it. I wonder if you would do that now?

A. I have the production figures here for Gray—let me explain this. I have them separated all right, but in utilizing—

Q. Just answer my question.

Mr. March: He is going to answer it.

The Witness: I want to make an explanation.

Mr. March: He is going to give you the production figures.

The Witness: While I set out two quadrants—I call them Quadrant 2 and Quadrant 5 in Gray County, because of the size and the position of it I utilized Gray County 5 and Gray County 2 together. I have separate figures for Quadrant 2 and Quadrant 5 but in the compilation I threw it in all as one quadrant because of its position.

By Mr. Keffer:

Q. All right, give me the figures on Quadrant 2 and Quadrant 5, Gray County.

A. The year ending August 1, 1935, zero production—

The Trial Examiner: From which—

The Witness: This is Quadrant 2, Gray County, 1936.

By Mr. Keffer:

Q. Just give the total figure.

A. For the four-year period?

Q. Yes.

A. For the four-year period, 865,360 Mcf.

Q. Now, just a minute. What quadrant was that?

A. Quadrant 2, Gray.

Q. All right, give me by years, then—let's see how you get that figure.

A. 1936, 144,465 Mcf.; 1937, 1938 and 1939—

Q. No, give it just for 1937.

A. Well, I'm going to give them to you. For some reason that I don't remember, we got a figure from the Commission records of a total of the last three years and we simply divided that equally for the three years of 24,300 Mcf. In other words, the tabulation would be 243 hundred; 243 hundred; and 243 hundred for each year consecutively for 1937, 1938 and 1939. I don't recall exactly where—how we happened to get that lump figure.

Q. Sir?

A. I don't recall how we happened to get that lump figure and divided between the three years.

Q. Could we have your working papers just a moment on that, Mr. Hammer? You don't want to change your answer on that?

A. Let me see those working papers a moment.

Mr. Spencer: Mr. Examiner, while they are looking at their working papers, may we have an exception to the Examiner's ruling a few moments ago?

The Trial Examiner: Yes.

By Mr. Keffer:

Q. Do you have them?

A. That's right.

Q. Now looking at your work sheet covering Quadrant 5 and 2, Gray County, what is the total figure that you have at the bottom?

A. That total figure that you would have at the bottom there isn't representative of 2 and 5 alone.

Q. Oh, what does that represent?

A. Well, you see in here is 2, 4, 5 and 6.

Q. All right.

A. I just picked off there—

Q. Let's take Gray County 4, for the purpose of illustration. What was the production from it for four years? Where are your years on that? I can't see it. What was the production in Gray County 4, 1936?

A. 14,718,527 Mcf.

Q. All right, what was the production in 1937?

A. Four?

Q. Yes, the same one.

A. 30,026,866.

Q. All right, what was the production in 1938?

A. 45,181,050.

Q. All right, what was the production in 1939?

A. 58,446,879.

Q. All right, now will you turn to your work sheets and show me what you show as the total production from Gray County 4 during those years?

A. That seems to be the only tabulation in these working papers that gives it.

Q. That gives it?

A. Yes.

Q. All right, where is it? Give me the figure.

A. Well, it would be the summation of these that I have just read.

Q. All right, just read your summation on it.

A. I would have to add it up.

Q. Haven't you got it already summed?

A. No, not individually.

Q. Let's go back, then, to that original sheet we were looking at on Gray County 2 and 5.

A. Well, this sheet right here.

Q. All right. You show me the accumulated production on Gray County 4 and you show it on the sheet you are now examining.

A. Again, that is the group accumulated there.

Q. I know, but you have it for each quadrant in the group, don't you?

A. Yes, but again I would have to pick it out and make an addition.

Q. Well, let's look down here. What is the figure—Gray County 4? Just read the figure there.

A. Wait a minute, I want to do a little checking here.

The figures that have already been read into the record are the correct figures for the four years.

Q. How do you mean, correct figures for the four years?

A. Well, I mean I have checked them. Those are the production by year.

Q. All right.

A. Now, to get the total I would have to add those together.

Q. All right. Turn to your Hartley County quadrant.

A. No, I'm going to finish this. Why hop to Hartley? Do you want this figure?

Q. All right, go ahead. I was just trying to help you a little and save a little time.

The Trial Examiner: Do you want the record to show that?

Mr. Keffer: It is already in the record. It doesn't make any difference.

The Witness: The figures are in the record.

The Trial Examiner: Very well. Go ahead, Mr. Keffer.

By Mr. Keffer:

Q. Well, let's turn to the Hartley County quadrant, Mr.

Hammer. Give me your annual production figures on that one.

A. All right, the 1936 figure, 793,677 Mcf.; 1937, 3,322,690 Mcf.; 1938, 5,112,209 Mcf.; 1939, 6,785,156 Mcf.

Q. All right, now, will you total those and tell me what the total production has been from that quadrant during that period?

A. The total figure there, unless I have made a mistake in addition, is 16,013,732 Mcf.

Q. That's right.

A. Or 16 billion—

Q. 16 billion plus as the total production from the quadrant for those four years.

A. That's correct.

Q. Now, again, you are trying to run into the word "approximately" there. That is the figure unless you have made some slight error in addition?

A. All right.

Q. Mr. Hammer, is that true of all your quadrants? Have you figured them that way in getting the total production in order to get your acre pound?

A. Yes, we got the total production by years.

Q. And then added them all up?

A. And then took the summation of the totals.

Q. And it is upon that basis that you determined your acre pounds, is that correct? by relating your pressure decline to your production figures?

A. Yes, annually; that is, taking it five years through.

Q. Well, now, those figures that you have there, as you have computed it there, if they are erroneous, then your acre pound figure would be entirely out of line, wouldn't it?

A. Those are the figures we got from the Texas Railroad Commission. If the Railroad Commission didn't have them correct, why—

Q. But even so, if you made an erroneous calculation there, then your acre pound answer would be an erroneous answer, wouldn't it?

A. Will you read that question, please?

(The question referred to was read by the reporter, as set forth above.)

The Witness: If you made an error, yes.

By Mr. Keffer:

Q. That's right, and in the approach you make of this field—the pressure decline approach is primarily a mathematical approach, isn't it?

A. It is an approach from the standpoint of mathematics and physics, that's right. It is a mathematical calculation.

Q. It has nothing to do with geology as such—it is a mathematical problem?

A. That's right.

Q. Now, Mr. Hammer, you feel that you did that correctly, of course, because in applying your formula if you didn't do it, why, your whole figure on a quadrant or on a field would be an erronebus figure, would it not?

A. If the formula were in error and was not applicable, of course, that is true.

Q. You would get an erroneous figure, but even if the formula were correct and you made an improper application with the figures you had you would still get an erroneous figure, would you not?

A. That is true. I don't think I did, but if I did I would have.

Q. I appreciate that, but in making a study of the character you have, you have to be very careful to be sure that you don't make a mistake in arithmetic?

A. Yes, where you have used as many figures as we have.

Q. Now, Mr. Hammer, what would you say if I told you you had made a very *grevious* mistake in the calculations you made there?

A. You would have to prove it to me.

Q. Would you be hard to convince?

A. I don't know as to that.

Q. All right, now, I am going to prove it to you. Now, I take it if I prove it to you on this you will agree with me that you might have made a lot of other mistakes and your figures would be all haywire, wouldn't they?

Mr. March: I object to that—

Mr. Keffer: I'll withdraw it.

The Trial Examiner: He withdrew it, Mr. March.

By Mr. Keffer:

Q. Now, Mr. Hammer, will you look at your Exhibit 180, Table 1, Page 5, and tell me what you show as the total production from the Hartley County quadrant?

A. 5, you say?

Q. Yes. The page is on the back. It is the tabulation you have there just following your statement—wait a minute. It's 2. Read the figure you see there set out already.

The Trial Examiner: What was that, Mr. Keffer? Hartley?

Mr. Keffer: Hartley quadrant. That is the one right at the top of the page.

The Trial Examiner: Yes, I see.

Mr. Keffer: The total production since August 1935 as shown on that schedule.

The Trial Examiner: Do you want him to read that into the record, Mr. Keffer, for the five years?

Mr. Keffer: That's right.

Q. Just read it in.

A. All right, I want to do some checking about the other figures I put in.

The Trial Examiner: Follow Mr. Keffer and then if you wish to expand on it or explain it, Mr. Hammer, you will be given an opportunity to do so.

The Witness: All right, though I want to explain it the minute I get through.

The Trial Examiner: That's all right, but follow Mr. Keffer.

The Witness: The figures on Table 1, Page 2 of Exhibit 180, 793,677—

By Mr. Keffer:

Q. I want you to give me, Mr. Hammer, if you have it there—

A. That's what I am doing.

Q. —the total production from the Hartley County quadrants covering the periods which you testified about a while ago.

A. Do you want that added up again?
Q. No.
A. Well, it has to be.
Q. What do you say at the top of that column?
A. I say, "Accumulated Production."
Q. What does that mean?
A. All right—
Q. All right, go ahead, then, and do it your own way.
A. All right, this is accumulated production.
Q. All right.
A. 793,677 for 1936.
Q. Now, let's go slow.
A. —and 3,322,690 for 1937; 5,112,209 for 1938; 6,785,156 for 1939.
Q. Those are Mcf. figures?
A. Yes, those are all Mcf.
Q. Now, do you want to add them?
A. No. The figures that I previously read into the record as being annual production figures were in reality accumulative production figures. In other words, I didn't notice "accumulated production" at the top of the column of the work sheet when I read them in, the figures that I gave

The Trial Examiner: Let's see, that was the figure for Hartley County, previously?

The Witness: That's right.

Now, in Table 1, Page 2 of Exhibit 180, the figure given there for 1936 is 793,677.

Mr. Lange: That is Column G?

The Witness: That's right.

All right, come down to 1937 and the figure on the tabulation just mentioned is 3,322,690. It is the same figure on the work sheet that was read into the record. Take 1938, the figure on Table 1 is 5,112,209. It is the same figure that is on the work sheet. Take 1939, Table 1 shows 6,785,156 Mcf., and it is exactly the same figures as shown on the work sheets; so the figures check.

By Mr. Keffer:

Q. All right, you do want to correct your statement, I take it?

A. As to those originals being yearly figures?

Q. That is right. I asked you right at the start if they weren't accumulative figures and you were very positive they were not.

A. That is correct.

Q. So an eminent scientist in mathematics where he has a mathematical problem may make a mistake?

A. I suppose that is true. It has been done.

Q. And even a rather simple problem?

A. Yes, that is true. It can be done.

Q. Now let's get back to Gray County and let's give the correct figures on Gray County quadrant which I was asking you about a while ago. You made the same mistake in Gray County that you made in Hartley County, didn't you?

A. I don't know.

Q. Check it and see.

A. Mr. Keffer, which quadrant were you referring to in Gray County?

Q. Quadrant 1 and Quadrant 2, the ones we were talking about.

The Trial Examiner: Is that Gray County, Mr. Keffer?

Mr. Keffer: I am sure that is what it is. It is Gray County, Quadrant 1 and Quadrant 2. If I made a mistake in stating it I want to correct that.

The Witness: I didn't know what I was checking.

By Mr. Keffer:

Q. I want them separately, Mr. Hammer.

A. Well, Gray County 1 is the small quadrant—the quadrant that has the small area inside the boundary.

Q. Well, here, isn't this the top boundary line I draw my pencil across?

Mr. Spencer: Across where?

Mr. Keffer: I can't read the map. I can't read the figures here on the map.

Mr. Lange: It is Quadrant 6, Gray County.

By Mr. Keffer:

Q. Just give me the acreage. That is a better way than any to determine the size.

A. If I have the acreage here I will give it to you. I don't know whether I have it available or not.

Q. Go ahead. We can look up the acreage later.

A. All right. That area down there didn't start to produce gas until 1939.

Q. All right, then, you had zero 1936, zero 1937, zero in 1938, is that right?

A. Yes, and it started to produce in 1939.

Q. All right, what did you have in 1939?

A. 80,513 Mcf. in that year.

Q. All right, give Quadrant 2.

A. The only figure I seem to have here is the accumulative figure.

Q. All right, read the accumulative figures year by year. You can determine by subtraction then what the production has been each year, can't you?

A. It could be done.

Q. Read the accumulative figure. Just read them. You have them there in front of you.

The Trial Examiner: Can you find the figures, Mr. Hammer?

The Witness: I can find the figures, but you see the thing that makes it difficult is that two of them have been combined.

Mr. Keffer: You had them all set out separately when we were looking at them on your work sheets.

The Witness: Yes, but what I am trying to do is to check back as to whether they are actually accumulative or are actual production.

Mr. Keffer: You can read the figures readily. I thought we decided what they were.

The Witness: Well, I want to do a little checking.

The Trial Examiner: We will stand in recess for five minutes.

(At this point a short recess was taken, after which the proceedings were resumed as follows:)

The Trial Examiner: The hearing will be in order.

By Mr. Keffer:

Q. All right, Mr. Hammer, will you read the yearly accumulative production figures on Quadrant 2, Gray County?

A. Yes.

Q. All right.

A. In 1936 it was 144,465 Mcf. Apparently—well, it is certain in 1937 some time there was a production of 95,385. The two added together would give you the total accumulated in the amount of 240,300 Mcf.

Q. That was accumulative production in what year?

A. Well, that came in in 1937.

Q. All right, give your figures for 1938.

A. No, I want to make this statement—

Q. Give the figures and then make the statement.

A. For 1938?

Q. Yes.

A. Well, of course, that was an accumulative figure taken through to get it.

Q. Just read it.

A. 240,300.

Q. That is what I wanted. Now read the 1939 figure.

A. 240,300.

Q. All right, that is what I wanted. Now go ahead and make your explanation.

A. All this discussion of this production in Quadrant 3 or in any other quadrant in arriving at, for the record here, the production figures, has made no difference and has made no error whatsoever in the calculations to arrive at the production per acre pound to be applied. It is simply an error in reading from the wrong column in the work sheets.

Mr. March: The figures in the exhibit are correct?

The Witness: That is right.

By Mr. Keffer:

Q. You told me a while ago there wasn't any error in the figures you were reading of annual production, didn't you?

A. Well, I have corrected that.

Q. Yes, that is right. And if you made a mistake in this other you reserve the right to correct it, too?

A. You mean in the calculation?

Q. Yes.

A. They were checked so many times I don't believe there were any errors.

Q. These were checked, too, weren't they?

A. Well, they were checked here *hurridly* on the witness-stand, yes. There is quite a difference between that and checking a bunch of figures yourself and having three or four other fellows check them over a period of three or four months.

Q. Did you yourself compile those figures and write them into your work sheets, Mr. Hammer?

A. Not all of them, no; very few of them, as a matter of fact, as far as the work sheets are concerned.

Q. Who prepared those figures?

A. Well, I had—I can't recall. I think principally as far as the compilation of these figures was concerned, it was done by two different men.

Q. Who were they?

A. A fellow by the name of Jack Daugherty and *Charels* Pettingall. I do remember very distinctly that in all cases they checked back against each other. In other words, I required if one figured out a bunch of calculations that the other would take those and then check them and they were checked and rechecked back and forth that way.

Q. They prepared your working papers, then, on your accumulative production figures and annual production figures, is that correct?

A. That is right.

Q. You had nothing to do with it?

A. Except that they would come to me and we would go over it. If there was an error I would say, "You check this and see that you are right. You check this and see that you are right."

Q. What part did Mr. O'Connor and Mr. Stevens have to do with the preparation of that?

A. The work sheets?

Q. Yes.

A. None whatever.

Q. How's that?

A. None whatsoever.

Q. I noticed Mr. O'Connor and Mr. Stevens were in conference with you to help you straighten out the mistake you

made during the recess. If they had nothing to do with the preparation of the papers, how did they know anything about it?

Mr. March: I object to that question. That presumes that Mr. O'Connor and Mr. Stevens did straighten him out on something. That hasn't been proven. Why don't you ask him whether he did?

Mr. Keffer: I will ask that very question.

Mr. March: You ask that very question.

By Mr. Keffer:

Q. Did Mr. O'Connor and Mr. Stevens assist you in properly interpreting your working papers?

A. Properly interpreting—

Q. Yes.

A. I wouldn't use the word "interpreting."

Q. What would you use?

A. They called my attention to certain things.

Q. I see.

A. That put me straight. Your men would do the same with you.

Q. Surely. Hadn't I already called your attention to the very thing?

A. Yes, I think you had.

Q. Then you already knew it, didn't you?

A. I didn't understand you.

Q. Oh, I see. All right, I am sorry, Mr. Hammer, if you didn't understand me.

Mr. March: As a matter of fact—

Mr. Keffer: What's that?

Mr. March: Do you want to know? If you want to go as far—

The Trial Examiner: I don't believe at this point the record reflects accurately just what figures you referred to as having been read into the record that were erroneous, Mr. Hammer.

The Witness: I will give you my remembrance and if I am not right, Mr. Keffer can check me.

Mr. Keffer: All right.

The Witness: I think it referred to arriving at the right accumulative production figures for Hartley County and arriving at the correct accumulative production figures for Gray Quadrant 2, and Gray Quadrant 1.

Mr. Spencer: I think there were also some figures in there with respect to Quadrant 4 that Mr. Keffer asked you about. I think that is what the Examiner has in mind. You did give some figures on Quadrant 4, Gray County, and I think the same thing would apply to those.

Mr. Keffer: Quadrant 4, Gray County, was where I was checking you on another work sheet, Mr. Hammer.

The Witness: That is correct.

Mr. Spencer: With the inclusion of that one, I think you have named them all.

The Witness. Those were the figures that we read off—well, those figures that were read off on Gray Quadrant 4 were also accumulative figures.

By Mr. Keffer:

Q. The answer you gave originally was erroneous as to those?

A. That is right.

Q. Getting back to Wheeler County, Quadrant 1—

Mr. March: Before we go further I want to make this observation: It has been intimated that Mr. Hammer has made some improper use of his associates—

Mr. Keffer: I made no such intimation and if it is so considered I will apologize to Mr. Hammer and everyone else. Is that sufficient?

Mr. March: When Mr. Rhodes was on the witness-stand he frequently conferred with his associates and we made no objection.

Mr. Keffer: I made not the slightest character of a suggestion—

The Trial Examiner: I recall very pointedly you made it on the record, Mr. March.

Mr. March: I might have done that but I never intimated Mr. Rhodes didn't prepare his own exhibit.

The Trial Examiner: I don't think Mr. Keffer intended to make any such intimation.

Mr. Keffer: I certainly did not.

Mr. March: That is satisfactory, then.

Mr. Keffer: I am simply trying to find the facts and that is all.

Q. Now, Mr. Hammer, when you excluded Quadrant 1 in Wheeler County, did you have much higher production in that quadrant than you had in Quadrants 1 and 2, Gray County, combined?

A. What is that accumulated figure for Quadrant 2, Gray County?

Q. Quadrant 2 has the figure of 240,300. I am quoting it from memory. Quadrant 1 was 80,513.

A. Yes, over a total period—

Q. A total period for the two quadrants, Quadrants 1 and 2, Gray County, amounting to something more than 320,000 Mcf., slightly more than that, is that correct?

A. 320,813.

Q. What was the production in the same period in Quadrant 1, Wheeler County? Give it by years.

A. This is for 1936, 79,105 Mcf.; 1937, 212,266 Mcf.; 1938, 316,324 Mcf.; 1939, 523,042 Mcf.; a total of 1,130,737 Mcf.

Q. Well, then, you had a lot more production from Quadrant 1 in Wheeler County than you had from Quadrant 1 and 2 in Gray County, didn't you?

A. That is right.

Q. As a matter of fact, Mr. Hammer, I am going to help you. Haven't you made the very mistake on Quadrant 1, Wheeler County, that we have been talking about on all these others, mistakes favorable to me? I am going to give you a chance to correct them so that the record may properly reflect the actual figures.

A. Will you read that question—not the statement but his question, if he had one?

(The record referred to was read by the reporter, as set forth above.)

The Witness: I don't understand that statement "favorable to me."

By Mr. Keffer:

Q. All right. If you had a great big production in Wheeler County, wouldn't that be one more reason to consider it in Wheeler County Quadrant 1?

A. You can't answer that categorically for the reason that here is a case where we are taking Quadrant 1 and Quadrant 2 in Gray County where new wells have been drilled and production has started to come out. For instance, we don't know yet what Quadrant 1 in Gray County would have produced over the same period of years to compare with this.

Q. I know that. Now let's get back—

A. You can't make a categorical answer because—

Q. I appreciate you can't, but if you had a quadrant in Wheeler County that was producing substantial volumes of gas today and had produced over a trillion feet of gas—

A. A what?

Q. A trillion feet of gas.

A. Oh, no, not a trillion feet.

Q. What was that figure you gave, the final total figure?

A. That is a billion cubic feet of gas.

Q. That is right, a billion feet of gas.

Still you couldn't have given a very good reason for leaving it out, could you?

A. Well, I think so. Let me analyze that a little bit.

Q. All right.

A. Here is a four-year period of production. Over that four-year period of production in that area there was only 282,678 Mcf. produced annually. That is the average. You take that 282,678 and divide it by 365, the average production that came out of that quadrant over a four-year period was only 774,000 cubic feet a day.

Q. What was it in Quadrant 2, Gray County, per day over the four-year period? It was a whole lot less, wasn't it?

A. But Gray 2 and Gray 1, particularly Gray 1, are new developments. You haven't any method of comparison. You haven't any method of comparison. You have no way to compare it.

Q. All right. You just had one year's production on Gray 1, didn't you?

A. I don't know whether it started in January or December.

Q. But you just had one year's production?

A. All right.

Q. Is that right?

A. That is right.

Q. And in Gray County 2 for the last three years you didn't have a foot of production, did you?

A. All right.

Q. You didn't, did you?

A. No.

Q. Yet in Wheeler County 1 you had production every year during that period, didn't you?

A. That is right.

Q. All right, and you had more production, not only did you have it every year, but you had more production from Wheeler County 1 than you had from Gray County 1 and 2 combined?

A. There is no argument about it.

Q. All right, I guess that answers the whole thing as I view it, at least, Mr. Hammer. Is that about correct?

A. As you view it, I think that is correct.

Q. Now, Mr. Hammer, if as a matter of fact we hadn't caught the error a while ago which you did mak and which you later corrected, it would have shown a much better picture for Gray Quadrants 1 and 2, wouldn't it?

A. What do you mean, it would have shown a better picture?

Q. It would have shown a continuous production every year and a substantial increase in the rate of production, and it would have shown substantially more production for the period, wouldn't it?

A. You mean if they had produced all the way through? Is that the intent of your question?

Q. If they had produced that as you originally said they did before you discovered your error?

The Trial Examiner: You mean had they produced those amounts each year?

Mr. Keffer: That is right, which he originally stated.

The Witness: Yes, that correctly stated that—

By Mr. Keffer:

Q. I say, you would have had a much better picture if you hadn't discovered your error?

A. No.

Q. Why wouldn't you?

A. In the method we employed that error wasn't made.

Q. Mr. Hammer, I am talking about one thing and you are talking about another. You said yesterday that you left Wheeler County quadrant out because it wasn't worth anything any more; it was depleted; there was no production in it, isn't that right?

A. I said it was my remembrance that it was—that there were a lot of dry holes in there.

Q. And there is no production now, is that right?

A. Did I make such a statement?

Q. I think you did. I think that is the very reason you gave for leaving it out.

A. The intent was that—I believe I put it that way—

Q. I think you did.

A —that there wasn't enough in there to warrant the assumption that it would amount to very much as a gas producing area.

Q. Notwithstanding the fact it had produced substantial volumes of gas and was previously producing substantial volumes of gas?

A. Well, I left it out and I stated my reasons for leaving it out.

Q. That is right.

A. All right. What more is there to say about it?

Q. Nothing, except when we come over to Gray County Quadrant 2 we have much less production and we have a period of three years where it hadn't produced a foot of gas, yet you kept that one in for the same reason, I take it?

A. No, no, no. I utilized that with Quadrant 5 and called it one quadrant in my calculation.

Q. But you utilized it?

A. Yes, I utilized it.

Q. You could have utilized Quadrant 1, Wheeler County, the same?

A. Yes, I could.

Q. Surely. When we come to Quadrant 1, Gray County, that had only 80,000 cubic feet of gas and one year's history behind it, you used that one, didn't you?

A. Yes.

Q. If the reason you gave for excluding Wheeler County, Quadrant 1, is a good reason, then you also for the same reason should have excluded Quadrants 1 and 2, Gray County.

A. That is a matter of judgment.

Q. That is right. We will let it stand that way. That is my judgment of it, nevertheless. You grant me that right, don't you?

A. You can have that judgment if you want to.

Q. All right. Now, Mr. Hammer, let's go back for just a moment. You have given us, I believe, the average weighted pressures for the field year by year as taken from your working papers, is that correct?

A. Excluding—I don't recall—no, those included Wheeler Quadrant 1, I believe.

Q. No, they did not include Wheeler Quadrant 1, the figures that you gave us for the year.

A. That is right. The first figures I gave you—

Q. Sir?

A. The first figures I gave you didn't include—

Q. Did not include Wheeler Quadrant 1, that is right.

There seems to be some confusion. Do you have the same figures for the field including Wheeler Quadrant 1?

A. Had you asked me for them?

Q. I thought I had.

Mr. Spencer: I asked you last evening for them.

The Witness: Didn't I give them to you, Mr. Keffer?

Mr. Keffer: No, you didn't. You gave me the 1935 figures but no more than that.

Mr. March: He didn't use Wheeler Quadrant 1, of course, in this exhibit.

The Trial Examiner: He was talking this morning—

Mr. March: If he has it, I don't object to him letting him have it, but if he doesn't have it, I object to his having to calculate it.

Mr. Spencer: No one has asked him to calculate it, Mr. March.

The Witness: That isn't necessary. I am quite sure that in my notes some place in the last year or two I have seen those for the entire field, including—didn't I supply you a figure last night?

Mr. Keffer: You gave me the figure for 1935 but said you would be unable to include any more, which included Wheeler Quadrant 1.

Mr. March: I think he explained all that. When we found he was going to use it, I think he explained that several times.

The Witness: I think that is true. I coudn't find the figure last night for the entire field, taking in Quadrant 1, Wheeler County—I couldn't find anything except 1935 weighted pressure.

Mr. Spencer: What did you have reference to a moment ago, Mr. Hammer, when you said within the last two or three days you had seen or had those figures available in your notes?

The Witness: What I started to say, Mr. Spencer, was, there has been some misunderstanding on my part in exactly what Mr. Keffer wants. It might be—I don't know, but in going over my papers last night I could only find the one. If I had been able to find the other I would have been glad to have given them to him.

Mr. Keffer: All right. I have one more question before we leave that.

Q. The fact that you left Wheeler County, Quadrant 1, out of your calculations for the field necessarily changed your estimate of the field, didn't it, Mr. Hammer?

A. Yes, it did.

Q. Very much?

A. Oh, for the entire field, in round figures, it made a difference of 720 billion cubic feet.

Q. 720 billion cubic feet?

A. Yes; out of the total ultimate field reserves which is very small in the—roughly about two and three-quarters per cent, or something like that.

Q. That 720 billion is as much gas as the Canadian River Gas Company produces in how many years? Is it about fifteen years? Wouldn't it be about fifteen years on a 14.65 basis?

A. That is true.

Q. That isn't such an insignificant volume, after all, is it?

A. But from my viewpoint, Mr. Keffer—you have expressed your viewpoint; may I express mine?

Q. Yes, however, I have just one more observation on that.

During the entire producing history of the Canadian River Gas Company and its predecessor companies that have been referred to, all of them combined haven't produced half that much gas up to this day, have they?

A. Well, up to August 1, 1939, I think your statement would hold. I wouldn't want to stretch it up until the present time.

Q. They have produced more than 300 billion—less than 400 billion, in their whole producing history. I have forgotten the exact figures used in these different pressure bases, but on a 16.4 basis during that period it was 328 billion, or something like that. Is that your recollection?

A. Up to August 1, 1935?

Q. August 1, 1939.

Mr. March: Are you using Mcf. or cubic feet, Mr. Keffer?

Mr. Keffer: Mcf. However—it would be 328 billion cubic feet.

The Witness: I think I have the figure in my notes. I don't know whether I have it here or not but I will agree.

By Mr. Keffer:

Q. Have you figured it? I see Mr. O'Connor has been shaking his head.

Mr. March: Mr. O'Connor didn't have anything to do with this exhibit.

Mr. Keffer: I thought Mr. O'Connor did, the way he was grinning.

Mr. March: He doesn't know what the figures are.

Mr. Keffer: That is all right. The record will speak for itself. It isn't so important except for comparative purposes.

Q. Will you give me again the difference it made in your field estimate of—it was 700 and how many billion?

A. 720 billion.

Q. 720 billion?

A. That is right.

Q. I want to write it down here.

The Trial Examiner: Cubic feet?

The Witness: Cubic feet.

By Mr. Keffer:

Q. 720 billion cubic feet?

A. Yes, sir.

Q. Did that increase your estimate for the field 720 billion up or 720 billion down?

A. It was 720 billion lower.

Q. Lower?

A. Yes.

Q. You got a lower figure than you otherwise would have gotten if you had included it?

A. That is true.

Q. Well, how did you arrive at that figure?

A. What figure?

Q. This figure that made a difference of 720 billion cubic feet.

A. Since this question has come up I have gone back and made a calculation—that is, utilizing the field as a whole by this method of calculation, not by the summation, but by taking the field as a whole, using Wheeler County. That is how I arrived at it.

Q. That is about the only way you could do it, isn't it?

A. Certainly.

Q. I was certain of that but I wanted to know what tools you used in making that calculation.

A. What tools?

Q. Yes.

A. You have your calculation there.

Q. What rock pressures and what production figures did you use?

A. Well, I used the same tools as I have used for the entire thing.

Q. I know. If you will just go through, briefly, your calculation and give me the rock pressures you used and the production figures you used, that is all there will be to it, Mr. Hammer.

A. I simply made a tabulation here and gave the comparative figures.

Q. I know—

A. I didn't attempt to—

Q. I know, but when you figure the field with Wheeler County, Quadrant 1 in it you had to have certain rock pressures and certain production figures, didn't you?

A. Yes.

Q. I want to know what the rock pressures were and what the production figures were. That is all I am asking you for.

A. Well, as I said, I don't have them here.

Q. Can you get those for me, Mr. Hammer?

A. I'll try to get them for you, yes.

Q. Well, you just worked it out last night.

A. No, I didn't say I worked it out last night.

Q. I thought you did. I thought you said since this came up. This came up yesterday.

A. No, I said since I came up.

Q. Came up where?

A. Up to this country. That's been about four months ago.

Q. Then you do have the figures in Denver?

A. Well, I did have them, but I say, I can't find them. That's what is worrying me. I don't know where they are.

Q. What was the idea of working this out since you came up rather than before this came up?

A. If you will recall, Mr. Keffer, when this question of total field reserve came up I utilized an expression that I believe some of your legal staff did not like, an expression that used the word—

Mr. Spencer: Do you want me to tell you?

The Witness: Yes.

Mr. Spencer: Academic?

The Witness: Yes, that's it academic. One of the reasons why I used that word "academic" was—and I am still of the same opinion that as far as utilization of anything way over in Wheeler County in connection with Canadian River problems is an academic problem and that was my meaning in that case.

By Mr. Keffer:

Q. Well, all right—

A. It had been an academic problem ever since almost I started to work with the problem, that anything way in the eastern end of the field in my opinion—or, rather, in our opinion, hadn't any bearing on the Canadian River situation and it was, therefore, an academic figure.

Q. Alright, now, I take it, then, that since this is an academic approach to the problem that we have here that that is the reason that you used the mathematical angle rather than the geological angle, is that correct?

A. I don't know how to answer that.

Q. Well, all right. Now, Mr. Hammer, I think it will clarify one thing, at least, and that is this coming up proposition that we are talking about. It just happened a lot later than last week, didn't it, this question of the academic problem coming up instead of you coming up?

A. The whole question there, Mr. Keffer, is this: In a problem of that kind and where I devoted most of my time because I had to in working out the problem relative to the western part of the area in which Canadian River has its acreage, there always was a question in the back of my head whether I should use that or whether I should not use it, and that was another point of this academic thing we are talking about, whether to use that figure or whether to not use it was an open question.

Q. Yes, but the point is you have computed the entire reserves of the field with Wheeler County quadrant in, included in the last ten days.

A. No.

Q. About how long ago was it?

A. Oh, I don't know. I have worked at it off and on whenever I could find time and gather a little information, pick it up here and there, and could get it together. I wouldn't know how long.

Q. Well, this thing just came up, I should say not more than ten days or two weeks ago at the outside.

A. Well, it has always been a problem.

Mr. March: I object to counsel arguing with the witness. I don't object to him asking the witness questions, but this is argument. The witness stated at the beginning with regard to Wheeler County when he asked him to give what the field reserve would be he said way back yonder he might have made the calculation but he couldn't tell, he didn't know. He has been doing some thinking about that and all these things are argumentative.

Mr. Keffer: All right. All right, if you will stop, I will.

Mr. March: All right.

By Mr. Keffer:

Q. All right, now, you have given us the weighted average pressures as you have computed them, Mr. Hammer, during the period which you covered in your study. Now, you check with me. It was yesterday that you gave these, your pressure—

A. May I see your sheet a minute so I can see what you are talking about?

Q. It is the weighted average pressure for the five points; that is, five pressure dates.

A. I gave those to you, all right. They are in the record.

Q. Yes, I just wanted to remind you what the figures were.

A. But I don't think I have the sheet I gave them to you from.

Q. You might take the figures down, then, as I read them back to you, because I want to make a similar calculation. All right, we'll take the weighted average pressure as you calculated it, Mr. Hammer, on August 1, 1935. That's the 369.25 pounds. Now, this is for the field as a whole with the Wheeler County quadrant out.

A. That's right.

Q. On August 1, 1936, 366.74.

A. All right.

Q. August 1, 1937, 352.02.

A. All right.

Q. August 1, 1938, 343.01.

A. All right, that's right.
Q. August 1, 1939, 332.98.
A. Read that again, please.
Q. 332.98.
A. That's right. That sounds right. They were read into the record. I read them in myself, I think.
Q. Now, from 1935 to 1936—August 1, 1935 to August 1, 1936, that gives you a pressure drop of 8.51 pounds, wouldn't it?
A. Just a minute, Mr. Keffer. I happen to remember that I do have the figures here and I just want to check them from my other notes.
Q. All right.
A. Yes, those are correct.
Q. All right, and the pressure drop from 8-1-35 to 8-1-36 would be 8.51 pounds, is that correct?
A. 8.51.
Q. 8.51?
A. That's right.
Q. And from August 1, 1936 to August 1, 1937, 8.72.
A. That's correct.
Q. August 1, 1937 to August 1, 1938, 9.01.
A. 1937 to 1938?
Q. That's right.
A. That's right.
Q. August 1, 1939—August 1, 1938, rather, to August 1, 1939, 10.03?
A. That's right.
Q. Now, that shows an acceleration in drop from year to year, doesn't it, Mr. Hammer?
A. Yes, it does there.
Q. Each year the pressure drop has been a little more than it has the year before, hasn't it?
A. Yes.
Q. All right, could you not expect the pressure drop to be a little more the next year than it has been this past year?
A. It all depends on the question of withdrawals.
Q. The question of what?
A. Withdrawals, gas taken out.
Q. Yes. Well, just what do you mean by that?

A. I wouldn't want to guess what it would be in the future.

Q. Well, say the production is the same as it was from August 1, 1938 to August 1, 1939.

A. If it would get back and settle down to a more or less definite withdrawal over a period of years, I think that that annual differential would also settle down to a very definite figure.

Q. Well, what do you mean by a very definite figure?

A. Well, I can't tell, whatever it would be.

Q. You just don't know, then? Is that right?

A. Well, I know what happened here.

Q. That's right.

A. All right. The point I make is that you have had an increasing withdrawal there for those years.

Q. And you account for those increasing pressure drops solely from increasing withdrawals, is that correct?

A. I think that is the largest factor.

Q. Well, then, I take it if production would go up, certainly you agree with me on that, then your pressure drop would increase, wouldn't it?

A. It might. It probably would. That's right, on the average.

Q. Well, now, do you want to say it would or it probably would or approximately so, or which?

A. Read that.

(The question referred to was read by the reporter, as set forth above.)

The Witness: Well, I'll tell you. I'll answer that this way; When you go from year to year over that short a period of time in a field as large where you take a field as large as the Panhandle field and you take out a lot of gas during one year, when you consider the field as a whole you will probably have, and in fact I am sure you do have, certain areas where because of low permeability factors the gas pressure does not build up rapidly in the wells; so to go to work and make a general assumption on what might happen in the future when you have all the factors entering into it, as far as I am concerned, I am not making any such statement at all. There are just too many unknowns that enter into it. There is nobody can predict what is going

to happen, but on the average it is true that withdrawals have their effect, but that is not only the effect; so that I won't predict what is going to happen in the future.

For instance, some of you fellows might suddenly decide it would be a good idea to go up to Hugoton and start taking a lot of gas and you might not take so much out of the Panhandle. You would have a different picture. There are so many factors that I am not predicting.

Q. You are not predicting that we are going to do that, are you?

A. I wouldn't be surprised.

Q. Now, do you want to base any of your estimates on that prediction?

A. No.

Q. Well, that's just an observation which has no particular weight in this record, is that correct?

A. That's right.

Mr. March: The same as the question. The answer was the same as the question.

Mr. Keffer: All right, Mr. March.

Q. Now, just taking that a step further, you do know, don't you, Mr. Hammer, that as pressures go down from year to year at an accelerated rate that you can expect that acceleration to continue in future years?

A. No, I won't—

Q. How's that?

A. I won't adhere to that assumption at all for the reasons I have explained. These pressures here are—some of them—these drops in pressure are probably artificial. In other words, you take an area of low permeability and you draw heavily on that well and what do you get? You get a low pressure. It may not have taken out a very large volume of gas because the gas couldn't move into it fast enough.

Q. All right.

A. The result is you get an artificially low pressure which would be reflected on this, so that you can't predict—

Q. All right, now, are you stating that as a fact?

A. I am stating that as a fact.

Q. All right, give me the wells in which that happened.

A. I can't give you the wells but I can give you localities.

Q. Do you know what pressure is subnormal—

A. What was that?

Q. How do you know that an accurate pressure as reflected by the pressure figures that you got from the Texas Railroad Commission are accurate?

A. Read that question.

(The question referred to was read by the reporter, as set forth above.)

The Witness: I recall definitely that on your own leases on your quadrants right down here in Moore County, in the center of that quadrant—

Mr. Spencer: Moore County?

The Witness: Potter County. I beg your parden—Quadrant 1, Potter County, in 1936 the pressure around your wells in the center of that went away low and what happened, it took almost the entire year for those to get back up to anything like normal, and what is the ultimate result? That low that developed in there in 1935 and 1936 was not entirely up and it took a long time for that gas to move in to build that pressure back up.

By Mr. Keffer:

Q. Now, will you please answer my question, Mr. Hammer, which is this: Do you know of any well in which the pressure which you utilized was not the accurate pressure? That was my question.

A. No, not the accurate pressure at the time it was taken, but it did not represent the true condition.

Q. Well, wait a minute. What sort of a pressure represents the true condition?

A. Well, if you took a well just as I have explained there—

Q. Yes.

A. Or an area or a group of wells—

Q. That's right.

A. —and you pull heavy on them and your pressure goes way down, then you follow that thing through and find out it takes a long time for that pressure to build back up. The answer is that that local pressure did not reflect the pressure of that area at all.

Q. All right, and threw you off on your pressure decline application?

A. No, it didn't at all.

Q. Why didn't it?

A. That was all weighted out.

Q. How do you mean, it was all weighted out?

A. Just as explained before. There is no use to go into all that again.

Q. All right, in your own assumption. Going back to the question I asked you some fifteen minutes ago, if you have the progressive declines in pressure accelerating from year to year, then it does mean something, on your own statement, because you said you have weighted it all out.

Mr. Lange: I object to that question because it presumes that the witness states, and which he did not state, that the pressures declined at an accelerating rate, which the witness has denied. The witness has denied that. You have assumed in your question that he has first answered the question affirmatively and I object to that question and ask him to reword his question for this reason. He can ask the witness whether they are accelerating or declining or not.

Mr. Keffer: I didn't think he had. I will ask him that.

Q. Are the pressures declining at an accelerated rate in the Panhandle field from year to year?

A. The records indicate that they are.

Q. They are? I thought so.

Now, Mr. March, do you want to apologize to me or not?

Mr. March: I thought you meant incremental pressures.

Mr. Keffer: I don't know what you mean by incremental pressures. Watch my questions and you will get what I mean, I think.

Q. All right, then, since they are dropping progressively from year to year, is it not a fair assumption that that will continue?

A. Well, as I said a while ago, I don't want to predict what is going to happen to pressures.

Q. Well, don't you have to predict that to apply your method and test it?

A. No, not into the future, not as far as pressures are concerned.

Q. All right, your method assumes that the condition is not going to change doesn't it?

A. My method?

Q. Yes, sir, the application of the pressure decline method.

A. No.

Q. All right, what changes have you assumed, then, for the future in the application?

A. I have assumed that gas withdrawals will continue according to straight line calculation. In other words,—

The drop in pressure in relation to the volume removed will in the average continue as it has in the past.

Q. Well, do you mean to say by that, then, that your drop in pressure must be geared entirely to production figures and that is the thing that determines the drop? Is that what you are trying to say?

A. Well, I am trying to say that, as I have already mentioned, that there are other things that throw your pressures off.

Q. But you said you had weighted all those out.

A. All, right, I have weighted them out and in my calculations the future is a straight line. It is not an incremental curve that goes down.

Q. That's quite true.

A. All right.

Q. Now, if the past is not a straight line, why would the future be a straight line?

A. The past is a straight line as far as the proper interpretation of the data is concerned.

Q. Well, the past isn't a straight line as a matter of fact, when you plot it on a paper, is it?

A. If you just take pressures alone, and I haven't plotted the thing—wait a minute.

Q. Be careful what you are doing.

Mr. March: We went over all that once. Does the Examiner want to hear it all over again?

The Trial Examiner: That's about what I was going to say, Mr. Keffer. Didn't we also cover this yesterday on cross examination? I don't want to interfere but—

Mr. Keffer: I don't think we did as applied to specific pressure data. I don't think so.

Mr. March: Oh, yes, you did. You took this big curve here.

Mr. Keffer: All right, then, if we have we will eliminate that. That was on Canadian River. I am talking about the field now.

Mr. March: Well, he doesn't have a curve on the whole field.

The Witness: Yes, I remember that in my notes here—I just happened to recall that I have got a curve for the field—I don't mean that, but I have a curve here covering 1935, 1936, 1937, 1938 and 1939, with the accumulated production for the entire field plotted against it, and I submit to anybody that that thing follows almost a straight line when plotted through those points, when you plot your pressure drop against your accumulated production.

Mr. March: Is that in your working papers?

The Witness: That is in my working papers. It is some notes that I had here and I happened to remember that I had that with me.

Mr. March: That is not a part of your exhibit?

The Witness: That is not part of my exhibit.

Mr. March: We haven't offered that as an exhibit?

The Witness: No.

Mr. March: There is no use talking about it, then, Mr. Examiner.

Mr. Spencer: The witness wants to talk about it, Mr. March. Let him go ahead.

The Trial Examiner: He brought it up, Mr. March.

Mr. March: Go right ahead, then.

The Witness: This particular thing I wanted to bring out, it wouldn't go clear on out, but it does prove that the—if you take these pressure declines he is talking about and plotted them against the accumulated production, there is your story, and it is a straight line.

By Mr. Keffer:

Q. Now, you said "straight line." It is a straight line because you drew it straight, isn't it?

A. Well, any engineer would draw it that way.

Q. Answer the question.

A. That's right.

Q. It is a straight line because you drew it that way, isn't it?

A. Any engineer, including myself, would do it.

Q. And if you went through the center of your points it would not be a straight line, isn't that a fact?

A. Yes, if you went through them, but that is not the way it is done. It is not the way anybody would do it that knows anything about his business.

Q. Let me show you another curve that is drawn exactly on the points and look at that and compare it with yours.

A. That is on pressure only.

Q. What's yours?

A. Mine is pressure against accumulated production.

Q. All right, where is your accumulated production?

A. It shows here. You can read it off the bottom, "The accumulated production, August 1, 1935, in Mcf."

Q. Well, what is it?

A. All right, this line here is 250. This would be something like 240 something. In other words, if you will check it you will find that figure I gave you at 240.

Q. What? thousands, millions, billions, or trillions?

A. It is in billions of cubic feet.

Q. Well, then, that's two trillion five hundred some odd, as you have it there.

A. Two trillion, five hundred billion, that's this particular line here, yes.

The 1935 to 1936 production was 650 billion cubic feet with a 8.51 pound drop in pressure. The next year, 1936 to 1937, the production was 600 billion cubic feet, and the witness would have expected the pressure drop to have been a little less, but, as a matter of fact, the pressure drop was a little more.

The next year the production was 616 billion cubic feet which should have indicated a little increase in the drop from the year before, and, as a matter of fact, there was a little increase, and the next year, 1938 to 1939, there was a production of 598 billion cubic feet. This production

was considerably less than the 616 billion cubic feet for the year before and was the smallest production for any of the periods. This being true, the witness would have expected a still smaller pressure decline when the matter is viewed from year to year, but, as a matter of fact, the loss in pressure was 10.03 pounds, the greatest drop for the entire period.

The witness further testified (Vol. 59, pp. 8368-8404) as follows:

Q. Then, production didn't determine pressure drop, did it?

A. There is no use to go into it again, but we will go into it again—

Q. You said a while ago it did.

A. I said there were qualifications—

Q. You got the qualifications into the record, I take it?

A. I said there were qualifications on this point.

Q. And the record speaks for itself. Let us have the record stand as it is.

When you plot a straight line, however you determine it, when ever you take the actual data you have here, you couldn't have a straight line regardless of what your paper shows there?

A. No, that isn't true.

Q. We will let the record speak for itself.

A. That is right, I can't calculate from year to year and get anything like a fair figure.

Q. All right, would you mind extending this curve for me about five or six years?

A. No, not unless the Examiner orders me to do so.

Mr. March: We object to that. We have gone far enough. This comes up and shows exactly what he has been getting at here. This is "Annual Pressure Drop, Panhandle Field, Excluding 1, Hammer's Data, Years." Now, he wants us to come along and he already thinks he is getting this exhibit put in through our witness, these curves plotted with our witness' data. Now, he wants the curve fixed up a little further along that line. We object. That is exactly in point with the Examiner's ruling. We have gone over fifty-five per cent of the way—

Mr. Spencer: Fifty-five per cent of the way?

Mr. March: One hundred per cent of the way.

Mr. Keffer: Most everyone has seen this chart. I will show it to the Examiner.

Mr. March: That is what you say it looks like.

Mr. Keffer: So does Mr. Hammer.

Mr. March: No, the witness didn't say that. You are plotting year for year—

The Trial Examiner: Never mind. The record will speak for itself.

Mr. Keffer: I will ask Mr. Hammer one more question.

Q. As a matter of fact, if that had been plotted against production as you say you did it, it would have been more extreme than what is shown in there, wouldn't it, Mr. Hammer?

A. No, that is not true.

Q. You are getting an increased drop with less production.

A. Yes, but as I have just stated, you can't do that from year to year.

Q. That is what you did?

A. No. I took a five-year period here.

Q. Five years?

A. I put those points on this curve pressure decline against accumulated production.

Q. That is right.

A. All right.

Q. If you put them on this curve against accumulated production you would have a curve dropping faster than this one?

A. No, that is not true.

Q. Take the last year, in 1938-1939, that is the fastest dropping point on the curve?

A. For one year only.

Q. That is right, and that was the least production?

A. All right. I have just explained how the—where you take the pressure on a group of wells you don't get a true pressure factor.

Q. But you have already stated you weighted all that

in, accounting for all of that, so there isn't any error in your own statement—

A. Yes, and I got a straight line curve through because I did it.

Q. What are we talking about?

A. You are taking something entirely foreign where you haven't used accumulated production—

Q. The point is—

A. —and where you haven't weighted out anything except for one year. You haven't taken an average of what happens over four or five years.

Q. We have the whole thing. So, yours is based on an average, is that it?

A. It is based upon an accumulated production as determined—

Q. Averaged out over the period?

A. No, it is worked out exactly with the same principle with the field as a whole on this curve, as it has been used on all these quadrants, that is all.

Q. Now you say—

A. You get the best slope through a series of divergent points.

Q. The whole point is—that is all right. I won't go into that any further.

Mr. Hammer, you say that low pressure areas throw you out of line somewhat, is that the point?

A. What I mean is this—yes, and no.

Q. Which one?

A. Wait a minute.

Q. All right.

A. In the study of this pressure situation we noticed that where wells in areas of low permeability have been pulled on heavily that there would be a rapid pressure drop clear out of line with anything else around in the same territory and it might take some little time for that to build up. Well, now, if the Railroad Commission's men had happened to come along and take those pressures on those wells right after there had been heavy withdrawals locally, they would have had a pressure that wasn't at all indicative of what that should have been.

Q. Is that what the Railroad Commission did?

A. In relation to the volume removed.

Q. Is that what the Railroad Commission did?

A. There is some evidence, yes, in places where they did do that.

Q. What is the evidence?

A. I don't have all those things here.

Q. Give me just one or two of them as illustrations.

A. I gave you one in your own acreage.

Q. That wasn't in 1939, was it?

A. When?

Q. That wasn't in 1939, was it?

A. No.

Q. All right, what did it represent to you? What did it tell you?

A. Do you mean during when you had that extremely low pressure?

Q. When you say "extremely low," how low was it? That is a relative term.

A. It is a relative term.

Q. How low was it?

A. I would have to get that information.

Q. It was about 380 pounds, wasn't it?

A. Well, what I meant there by "relative," was that it was extremely low as compared with the area immediately adjoining it.

Q. Several miles away from there you had a pressure of around 390 or 400 pounds?

A. Yes, they are high in close to it.

Q. How close?

A. Oh, I would say—let's put it this way. Just assume—I don't remember—that your pressure was 380 that you took.

Q. I think some was more than that.

A. For the purpose of illustration I will assume it was that.

Q. All right.

A. If you take a 10-pound isobar, say, take your 390, the total slope where you would get up to—rather, the pressure differential gradient wouldn't extend out, according to my memory of it, to exceed two miles from the well at the most.

Q. You say that is from your memory. How good is your memory on that?

A. Well, I think that is about right.

Q. As a matter of fact, didn't it extend out several miles?

A. No, I don't think so.
Q. You don't think so?
A. No.
Q. Didn't it extend out several miles as shown on the Railroad Commission's map?
A. That isn't the way it looks when you get a map on 10-pound isobars.
Q. I am just looking at one here and I don't see anything about it.
A. That is for 1939. I was talking about 1935.
Q. It was the one you left in Washington, I take it?
A. That is right.

Mr. Keffer: That is all for the morning session, Mr. Examiner.

The Trial Examiner: The hearing will stand in recess until 2:00 o'clock this afternoon.

(Whereupon, at 12:30 o'clock, p. m., a recess was taken until 2:00 o'clock, p. m., of the same day.)

Afternoon Session—2:00 P. M.

The Trial Examiner: The hearing will be in order. Whereupon—

A. A. HAMMER

the witness on the stand at the time of recess, having been previously duly sworn, resumed the stand and testified further as follows:

Cross Examination (Continued)

By Mr. Keffer:

Q. Mr. Hammer, we were discussing a while ago the pressure drop field-wide in the Panhandle, it was increasing from year to year, that is, during the entire period covered by your study the pressure drop increased in every instance, in no one year greater than it had increased the preceding year, is that correct?
A. There had been an increase.
Q. That is right. That happened without an increase in production. In fact, your greatest pressure drop in any one year, which was the last year, showed the smallest production in the period, didn't it?
A. I think that is true.

Q. All right. Now, you have tried to draw a straight line reflecting that matter when as a matter of fact your actual factual data doesn't show a straight line, does it?

A. It does when properly drawn.

Q. Well, it is properly drawn when you put it right on your ordinate points, your graphic point, isn't that true? That is proper and that is actually what it is, isn't it?

A. Yes, it is, the way I drew a curve. That is actually what it is.

Q. That is actually what happened in the field?

A. Yes, where I plotted my dropping in pressures against the accumulated production, that over a five-year period is actually what is happening to the field.

Q. As you plotted it you didn't show an accelerated drop from 1938 to 1939, did you?

A. On the actual points, if you take it from one year to the next without consideration of anything else, it showed it there. In other words, if you draw one of the crooked curves you are talking about, to which I don't agree, but if you drew it that way you would have a curve that followed divergent points.

Q. You say if I drew it my way. My curve on the exhibit presented to you was represented by actually what happened in the field. There wasn't any judgment about it. That is exactly what it was.

A. You are talking now about the curve you drew?

Q. Yes.

A. You left out one of the very important factors there in the projection of the curve.

Q. What?

A. You simply drew a curve on pressures against years.

Q. The pressures against years, that is true. It showed what was happening each year.

A. As far as pressures alone are concerned, I will agree with you.

Q. All right. Since the production from August 1, 1938 to August 1, 1939 was the smallest production in the volume of the entire period covered by your study, and since the pressure drop without production being considered was the greatest, and the production had been plotted in there, too, as you did it, the slope of the line from August 1, 1938 to August 1, 1939 would have been more decided than what I showed, wouldn't it?

A. If you take one year, but I have repeatedly said that it isn't a fair way to judge a field of this type or any other field.

Q. Well, I know you have said that.

A. It is true.

Q. If you take a period of years and you get a trend and you see that each year is getting more and more and more, then do you think you can ignore that trend?

A. I haven't ignored it. All I have done is to weight it out and get a fair curve.

Q. What you did was to just draw a straight line through that?

A. It is a straight line, that is true, and that is the line it should be.

Q. You say it should be. How do you know it should be a straight line?

A. That is the way any engineer in the world would draw it?

Q. Why should it be a straight line?

A. Because in order to get a fair answer you must take into consideration not what happens in one year but what happens over a period of years.

Q. Take it over a period of years, still you don't get a straight line, except you arbitrarily make it a straight line with a straight-edge ruler.

A. That comes right back—

Q. You take your own points. You don't get a straight line if you connect your points—

A. If you connect it from point to point, of course you don't.

The Trial Examiner: Through the center?

Mr. Keffer: Through the center.

Q. How do you know that line ought to be straight?

A. It has to be straight.

Q. Why?

A. Any line has to be straight under conditions and under the method which we have employed, that is, the application of Boyle's law.

Q. Why does it have to be straight? Please answer my question.

A. The volume removed always bears a direct relationship to the drop in pressure.

Q. Yet it isn't straight when you connected it from point to point and center to center?

A. Well, those divergent things always come in in any field, but it has always been the practice, and it is the practice now of the great majority of geologists and engineers who employ the pressure decline, to utilize that same principle of arriving at a slope for their curve.

Q. What principle?

A. Well, the principle of getting the best slope that you can through a bunch of divergent points.

Q. The principle of getting a straight edge and drawing a straight line through there where you want it to come out?

A. That is not true.

Q. Isn't that what you actually did?

A. I drew it where the average weighting of the four years of pressure and the five years of production said it was the closest possible to get it.

Q. And you ignored the accelerated drop from year to year?

A. Let's go back a minute. If you had drawn a curve between 1937 and 1938 you would have had a slope that would have given you a different one, wouldn't you? Certainly it would. It would have given a very much larger indicated production than would be the true figure, taking it over a period of years.

Q. Tell me what that would have given you. Would that have given you the indicated production if you had drawn the slope between 1937 and 1938?

A. Well, you would have had a less drop in pressure—

Q. I know, but I want you to give me the figure. It is a very easy figure to get. I can work that problem myself.

A. Between 1937 and 1938, you say?

Q. Yes.

A. Well, your actual drop between 1937 and 1938 was 9.01.

Q. All right, 9.01. What is your production for that period?

A. I believe I gave you the accumulated production.

Q. The accumulated production for that year?

A. May I have that document you have there? I don't seem to have mine with me.

Q. I will give it to you. It is 616,439,219.

A. Read that back to me. I couldn't keep up with you.

(The question referred to was read by the reporter, as set forth above.)

Mr. Keffer: All right.

Q. Now divide your 9.01 into your production for that year.

A. May I leave off the .01? It would be easier to use just the figure 9.

Q. I will tell you what we have done. We have figured it out accurately here, Mr. Hammer, and to save time let's get it into the record and the basic figures can be checked very readily.

You divide 9.01 into the 616,439,219 and you get an average production per pound drop in pressure of 68,417,227 cubic feet. That is not Mcf. but cubic feet. You multiply that by 430 and get a calculated original field reserve of 29,000,407,610 Mcf.

In other words, it is 29 trillion plus.

A. Yes.

Q. Let's look at your graph again.

A. My graph won't take that in because it was only illustrated to cover the five-year period.

Q. I understand that. What calculated field reserve does your graph show?

A. I said this isn't projected on through.

Q. Project it on through and see what it shows.

Mr. March: We object to that, if the Examiner pleases. That is another little mathematical problem he wants him to work out for him.

Mr. Keffer: Anybody can project it. It is perfectly a straight line and all you have to do is to run it out.

Mr. March: I guess if anybody could, you could bring a witness here and have him do it.

Mr. Keffer: Even you could do that, Mr. March.

Mr. March: We object to that, Mr. Examiner.

The Trial Examiner: What was the statement you were about to make, Mr. Hammer?

The Witness: This only illustrates that if you could properly project that curve not into the future but through the five years of data that we used, it follows a straight line. That is the object of putting it in properly projected. It wasn't ever projected into the future. It would take a lot of additional and coordinate paper and different scales, and it would be a job that would have to be done all over.

By Mr. Keffer:

Q. As a matter of fact, Mr. Hammer, as you did on some of the Canadian River's exhibits, all you have to do is come back and keep drawing straight lines and you would have it there. You haven't any deviation in it and you say it is already figured out correctly.

A. It would take quite a little time to do that. I doubt whether the scale laid out here—no, I know you couldn't get it on there. You wouldn't have room.

Q. Does that include Quadrant 1, Wheeler County, as you have the line drawn there?

A. Well, I don't know whether it does or doesn't from looking at this sheet. I think we can check it from those accumulated figures in the field which I gave you.

Q. Tell me how you constructed it. That would give the facts.

A. This was constructed in Washington from the field data and I might have already given you that accumulative production.

Q. Go back in your working papers and get the basic data for that graph and see what it is. See if it is interpreted the same as those figures you gave me.

A. That would take time.

Q. You would just have to read a page, that is all. That is a very small thing to do. Just look in your working papers and see what pressure you had here rather than looking on this graph. See what your production figures were.

Mr. March: If the Examiner pleases, it may be that we will offer this as an exhibit. This has nothing to do with the computation of the reserves and the exhibit which has been offered. That merely is something that is illustrative of the results. It has no bearing upon arriving at the results. It is a check. This whole discussion was volunteered by Mr. Hammer in regard to the whole field and it wasn't

prepared as an exhibit. Commission's counsel hasn't offered it as an exhibit, however, at which time it does you will be entitled to all of the data surrounding it just as you have been entitled to the data surrounding Exhibit No. 180.

In Exhibit 180 the same type of curve is found on Page 4-B which the witness has been cross examined about, and there is a sheet in there giving the details as to how that curve was arrived at. I will assure Mr. Keffer that when that is offered as an exhibit he will be entitled to test it completely. That was something volunteered by this witness which Commission's counsel did not offer as an exhibit.

There is another one just like it in the other exhibit you have already asked him about, Mr. Keffer, Exhibit No. 180, involving the Canadian River's acreage.

By Mr. Keffer:

Q. Mr. Hammer, we were discussing this matter yesterday and you gave your original field per acre as 72.2 billion cubic feet per pound drop in pressure, didn't you?

A. For what?

Q. For the entire period which you have considered.

A. Well, I don't know offhand. The record will show what I said or what was brought out. I don't remember it now.

Q. All right, you gave us a figure—your ultimate reserve figure, as you call it—at 25 pounds abandonment as 29,277,—

A. Yes, that is my recollection.

Q. You don't know whether that included Wheeler County quadrant?

A. From memory, I don't.

Q. You don't recall?

A. It would only make 700 billion difference anyway.

Q. Yes, you said that. That 29,277,000,000,000, the round figure you gave, represented a production of 405 pounds out of the reservoir down to the 25-pound abandonment?

A. Yes, if you take 430 as the original pressure.

Q. Isn't that correct? Isn't that what you have taken?

A. That is what I have used. There has always been a doubt in my mind whether it is true, but I have used it.

Q. You have used it?

A. That is true.

Q. You divided 405 into 29,277,000,000,000 and you got 72.2 billion?

A. I haven't divided it out.

Q. The round figures were given here and it is a very simple calculation to divide it out. See if you can't do that.

A. What are the figures?

Q. I think you did it yesterday and I think the record already shows it.

A. 29,277,000,000,000?

Q. That is right.

A. Divided by what?

Q. 405.

A. It is 72 plus.

Q. I have 72 plus, too. Does that look about right? I think that is about where you would hit it.

A. It is closer to 72 plus.

Q. 72 plus 2. All right, that is the production per pound pressure drop that you got on your calculation; it might have included Wheeler County quadrant or not. That is the only questionable thing about it.

A. It is so small in relation to the whole it wouldn't make much difference.

Q. All right, let's keep that figure in mind, Mr. Hammer, and go back to that pressure drop from 1937 to 1938 where you had a 9.01 pressure drop which the record shows. If we divided that into the production of that year of 16,439,219 Mcf., would we have gotten the pressure drop of 68,417,227 as against your 72 million plus?

A. That would be right if you want to make that comparison.

Q. All right, then, we go back to the year 1936-1937 when you had an 8.72 pressure drop as against 600,013,041 Mcf. and divided your 8.72 into that. You get a production per pound pressure drop there of (copy illegible) 68,808,835 Mcf., is that right?

A. I don't know whether it is right as I haven't figured it.

Q. Anybody can figure it from the record. All of the basic figures are there.

Mr. March: Mr. Examiner, this is doing exactly what I said was going to be done and I think it is contrary to

the Examiner's ruling. He has taken his computations and is trying to get this witness to agree to them.

Mr. Keffer: I have taken the basic figure which we agreed upon and I have given him my computation.

Mr. March: That is the point. The Examiner's ruling was he would have to do it through his own witness.

You went half-way with Commission's counsel, Mr. Examiner, in stating that you would instruct the witness to check the actual figures that were taken off of his working papers, but you would not require the witness to approve or disapprove or compute the computations made by counsel here and his associates as to the results therefrom.

Mr. Keffer: I gave an assumed figure which he can come back to later.

Mr. March: I object to that line of cross examination because it is improper and it doesn't mean a thing in the world. This witness can't compute all this on the stand here. If he wants to bring in this other estimate, if he wants to do it a different way, he can bring it in here through his own witness.

Mr. Keffer: I am doing it Mr. Hammer's own way. I have been trying to point it out all the way through this cross examination. These are his figures.

Mr. March: That is the point, Mr. Examiner. In spite of the Examiner's rulings he will say that all of this is Mr. Hammer's computations, the results therefrom, he approved everything, which is not the correct situation.

The Trial Examiner: I think, of course, the important thing is that the computations be correct.

Mr. Keffer: They will be self-evident, Mr. Examiner. All of the figures are there where anybody can divide it out.

Mr. March: Mr. Hammer's working papers are not in the record.

The Trial Examiner: I don't know, Mr. Keffer. It seems to me that it is rather burdensome to the witness to have to check those amounts.

Mr. Keffer: May I make this statement, Mr. Examiner?

The Trial Examiner: Yes.

Mr. Keffer: Assuming my calculations are correct, the figures are in the record where the Examiner, Mr. March, or anybody can check to see whether I made them accurately, just as though I would say we have 2 and 2 over here and it makes 4. Mr. Hammer doesn't want to say that 2 and 2 makes 4 but the record is clear and that is precisely—

Mr. March: He takes a piece of wood from over here out of this wood and takes a piece of wood out of here and makes this building but it is his child and not our child. It is not proper cross examination, Mr. Examiner. It is contrary to the Examiner's ruling that was made today.

Mr. Keffer: These pressure declines and production figures are the identical figures which Mr. Hammer has already given. There is nothing to assume about those as they are in the record.

Mr. March: We may want to cross examine the man who says they and his results—

Mr. Keffer: That is the same. Your own witness gave them.

Mr. March: That is the point. They can put on their case when they come back on. This witness can be cross examined on this exhibit but when they bring up a new exhibit, one of their own brain childs, and cross examine our witness in regard to it, attempt to have him stipulate as to the computations—we will stipulate as to it when they take his figures off the working papers—but when you go to computing from their exhibit it goes beyond the realm of proper cross examination.

The Trial Examiner: I do think this: The basic figures, you have verified those through Mr. Hammer. Now, as to the computations made from those figures, I am not inclined to view them as improper or erroneous, but at the same time I am hesitant to thrust that burden upon Mr. Hammer to satisfy him—

Mr. Keffer: I wouldn't ask Mr. Hammer to do that. It will be entirely up to him as to whether he wants to do that.

Mr. March: He wants to put the witness into a position

of where he has to say yes or no to something he shouldn't even be cross examined about, a new exhibit that is different altogether. He wants to come through the back door and put in an exhibit which is not ours. If he wants to put in an exhibit, let him bring his own witness in here.

Mr. Keffer: Let me make one statement, Mr. March. I could have said it in half this time, half the time we have been talking here. Mr. Hammer has made the statement many many times that he has taken a conservative course. In one or two more questions I can prove not only that he did not do that but he took the highest figure he could get out of a group and didn't average anything. If that isn't legitimate cross examination I don't know what is.

Mr. March: That is his argument, that he did, and Mr. Hammer denied he did. If he has any witnesses, which he has, let them figure that out. If those geologists use Mr. Hammer's figures and figure it out that way, in all righteousness he should have nerve enough to put those geologists on the stand here and let us cross examine them.

Mr. Spencer: We have plenty of nerve, Mr. March.

Mr. March: I will say you have.

The Trial Examiner: I take it, then, Mr. Keffer, for the purpose of further cross examination it will be necessary that this computation that you speak of be used?

Mr. Keffer: I am not sure that I understood the Examiner precisely. The only figures we need, Mr. Hammer has already given us. I am cross examining him as to the accuracy of those figures. He has given them and I am taking those figures. It is a mere matter of taking a certain figure by the pressure therein and multiply by 430, which he said was the way to do it, which the Examiner could do—any of us could do that, and I am putting those basic figures in and saying that this is what it shows. It is there for anyone to check who questions it. I am not asking Mr. Hammer to do a thing.

Mr. Spencer: Mr. Examiner, before you rule, may I put it another way. Mr. Keffer has tried to expedite this hearing but suppose Mr. Keffer would ask the witness this question: "Mr. Hammer, take your rock pressure decline for a specific year, also your production for that year, and

tell me what the indicated reserves are for the field base upon that year," would the Examiner rule that question was not relevant and not material? It is using his own figures for that year, asking merely the question as to what the indicated reserves are for the field, based upon that year.

Mr. March: The way he figured—now he is cross examining the Examiner.

Mr. Spencer: That is what we are getting down to.

The Trial Examiner: I think I have expressed myself on that before, Mr. Spencer, the relevancy of that particular thing, but we are coming now to a point as I see it—maybe I have the wrong slant—where Mr. Keffer I believe requested Mr. Hammer to make a certain calculation—

Mr. Keffer: I am not going to ask him to make a calculation.

Mr. March: Some calculations have already been made by him. It is the same old horse.

The Trial Examiner: In order to verify the calculations—as I say, I don't feel it is improper cross examination, but at the same time I am not concerned about Mr. Hammer having to verify—not "verify," but having him to affirm a figure that is submitted to him.

Mr. Keffer: I am not asking him to affirm a figure.

The Trial Examiner: Just what are you asking him, Mr. Keffer?

Mr. Keffer: Let's proceed—

Mr. March: Let's don't proceed. After the horse gets out of the corral there is no use of corraling the horse.

Mr. Keffer: In order to protect our record I am going back and ask these questions one by one, and since the objection has been made that they don't want any calculation, I am not going to give a calculation I have made but I am going to ask Mr. Hammer to make a calculation in order, as I have stated, to protect our record in this matter. I am perfectly willing as far as I am concerned—

Mr. March: Either way is the same.

You ruled this morning, Mr. Examiner, that you would permit him to verify any of his actual figures taken from his actual working papers, but when it came to making him calculate or verify calculations from those figures furnished by counsel here, you said that was something that you would not insist the witness comply with.

The Trial Examiner: I believe I said, Mr. March, that I would not require him to affirm the accuracy of the calculations made on the particular sheet to which you were referring this morning. Let's go along and see what develops, Mr. Keffer.

Mr. Keffer: All right.

Q. The pressure drop as you have heretofore stated, Mr. Hammer, from August 1, 1935 to August 1, 1936 is 8.51 pounds average for the field?

A. Yes, that is right.

Q. The production from August 1, 1935 to August 1, 1936 was 615,778,940 Mcf. as you have stated?

A. I don't have the figure but I will assume that is correct.

Q. Now, Mr. Hammer, what was the production for that year per pound pressure drop?

A. Well, I didn't write that figure down. I didn't know what was coming up here. You didn't say you wanted it calculated so I didn't write it down.

Mr. Spencer: I think the other method would shorten this a great deal.

Mr. March: I object to that. I want the Examiner's ruling so the record will be clear as to his calculation. I understand that the Examiner's ruling is that he could calculate it—

The Trial Examiner: I haven't ruled anything.

Mr. March: He is just about to start so we want to get our objection in now.

Mr. Keffer: I have asked a question of counsel—

Mr. March: We object. May we have a ruling Mr. Examiner, before he calculates it?

The Trial Examiner: Mr. Reporter, please read back the record starting with that question.

(The record referred to was read by the reporter, as follows:

"Q. The production from August 1, 1935 to August 1, 1936 was 615,778,940 Mcf. as you have stated?

"A. I don't have the figure but I will assume that is correct.

"Q Now Mr. Hammer, what was the production for that year per pound pressure drop?

"A. Well, I didn't write that figure down. I didn't know what was coming up here. You didn't say you wanted it calculated so I didn't write it down.")

The Trial Examiner: You may answer.

The Witness: Am I to calculate it?

The Trial Examiner: You understood what he has requested you to do, Mr. Hammer?

The Witness: Yes, he wanted me to divide this production from August 1, 1935 to August 1, 1936 by the drop in weighted pressure.

The Trial Examiner: I think I will take a short-cut on this thing. It seems to me like we are wasting quite a bit of time in going through this thing step by step.

Mr. Keffer: That is the only step there is to it.

The Trial Examiner: All right, then.

Mr. Keffer: Did you mean to ask if there would be other questions, Your Honor?

The Trial Examiner: That is what I meant.

Mr. Keffer: Yes.

The Trial Examiner: But you will ask the witness to make the calculation year by year?

Mr. Keffer: I will state what it is and he is to divide 9.81 into that to see that it is correct.

The Trial Examiner: It would seem to me that it would be unnecessarily taking up quite a bit of time on this particular matter as they will be the figures we were discussing a short time ago. As a short-cut to this particular question,

I wish you would again ask it and I will give Commission's counsel an opportunity to object.

Mr. Keffer: All right. Going back, then, to production for the period August 1, 1935 to August 1, 1936 of 615,778,940, Mr. Hammer's figure, the pressure decline weighted for the field is 8.51; divided into the production gives the total of 72,359,452,000 cubic feet per pound pressure drop. That is all the whole thing is right there.

The Trial Examiner: That is your question, then.

By Mr. Keffer:

Q. Let us assume, Mr. Hammer, that that is correct—

Mr. March: To which we object

The Trial Examiner: Objection overruled.

The Witness: I haven't calculated it.

The Trial Examiner: It will be understood, however, that that figure, in the event it is determined it is erroneous, is subject to correction.

Mr. Keffer: Of course, I am taking that chance.

Mr. March: Also, he is assuming his method is correct.

The Trial Examiner: Irrespective of the method, I mean that the figures should be subject to correction in the event they are found to be incorrect.

Mr. March: We don't want anything to do with these figures.

The Trial Examiner: I understand, Mr. March.

By Mr. Keffer:

Q. Mr. Hammer, that computation was for the year 1935 to 1936. We had already computed it for the years 1936-1937 and 1937-1938 and in each of those years it was 68 billion, plus, as I stated the computation to be, is that correct?

A. Yes, that is what you said it was.

Q. Just one more question and we will be through.

The year from 1938-1939, the pressure drop that years was 10.03 as you gave it?

A. That is right.

Q. And the production for that year was 598,138,886 Mcf. as you gave it?

A. I assume it is. I don't have the figure.

Q. You gave me that figure

A. Well, all right, I don't have the—I don't have anything to check it against.

Q. I wouldn't think you would want to check your own figure. Dividing 10.03, the pressure drop, into the 598,138,886 it gives a production per pound pressure drop of 59,634,979. We will assume that divides out that way, Mr. Hammer.

A. That is your division.

Q. That is right. Upon that assumption when you calculate yours, the basis upon which you calculated the field reserves, you get a pressure drop—I mean, you get a production per acre pressure drop of 72, billion, don't you, plus 72.2 billion?

A. Well, I didn't carry it out. I would say it was 72, plus.

Q. That is right. Now, the calculations we have just made, assuming that they were made correctly, shows your very highest production figure per pound pressure drop to be 72 billion, plus, doesn't it? That is assuming that I calculated it correctly.

A. Assuming that your method of arriving at it was calculated correctly, yes, sir.

Q. And it drops down each year progressively, doesn't it, until in the year 1938-1939 it reaches 59 billion, plus?

A. That is what your tabulation shows.

Q. Assuming that I have figured that correctly, when you say that you took an average of them and came out with 72 billion, that could not possibly be correct, could it? Isn't that obvious?

A. If your calculations are correct there, it would be.

Q. That would be correct?

A. I said it would be obvious if your method is correct.

Q. I used the same method you used a while ago, precisely.

A. No, you did not.

Q. What was the difference?

A. That 29 I gave you as a figure was arrived at by the summation of the calculated reserve by all of the quadrants in the field.

Q. I know. You have stated that a number of times, but still when you calculated the per pound pressure drop, production per pound pressure drop, it was the equivalent of 72 billion per pound pressure drop, wasn't it?

A. Yes, it was 72 according to those—

Q. The statement I made was, if my calculations are correct it is still sound and it was a correct statement?

A. Well, we will say until they are checked that it is.

Q. Let's go to one other phase of this matter, Mr. Hammer. You have already checked your data as to acres and quadrants and as to acre pounds in each year, which was taken directly from your working papers in so far as the Canadian River's area is concerned?

A. I checked all except the totals.

Q. That is correct?

A. I assumed they were correct.

Q. Now, to get the weighted average pressures from year to year of Canadian River, you divided your number of acres into your acre pounds for each year?

A. That is right.

Q. For 1935 that gives you 39.92. That is arrived at by dividing 443,691, the total number of acres in those various quadrants, into 177,440,264 acre pounds?

A. Yes, that is the way you would calculate it.

Q. Then if you had the weighted pressures from year to year on Canadian River's reserves—I don't see how you could fail to have them—we could short-circuit a lot of this, that is, if you will just give them to us, because you had to have them, certainly, when you figured this Canadian River picture, otherwise you couldn't have done it. These are the entire quadrants that the Canadian River acreage is in, which is the way you approached the problem.

A. Well, the weighted average pressures for 1939 are on Table 4.

Q. That is for Canadian River's acreage alone?

A. No, no, that is for the quadrants in which Canadian River's acreage occurs.

Q. I think you are wrong—

A. I know I am not.

Q. Those are weighted pressures for each quadrant but they are not weighted for the area? It is impossible to tell the weighted pressures for the area without weighting those as to each quadrant, that is correct, isn't it?

A. What do you mean by the area?

Q. The quadrants which you considered in making the Canadian River's reserves estimate.

Mr. Spencer: All of them.

The Witness: I never made any such computation.

The Trial Examiner: You mean by that, Mr. Keffer, the group he used in determining one quadrant?

Mr. Keffer: The groups the witness took into account in his balancing operation as stated, to find the Canadian River reserves.

Mr. March: Mr. Examiner, that is all contained and written out in the exhibit.

Mr. Keffer: That is just the point, it isn't.

Mr. March: It isn't?

Mr. Keffer: No.

Mr. March: Why don't you ask the witness whether it is or not?

Mr. Spencer: He has been asking him that.

Mr. March: Did he say it wasn't?

Mr. Keffer: How's that?

Mr. March: He didn't say it wasn't in there.

Mr. Keffer: Yes, he did.

The Witness: I did not. You didn't give me time.

Mr. Keffer: You said you had the weighted average for each quadrant.

The Witness: You didn't give me time to go through it.

Mr. Keffer: I beg your pardon, I thought you were through answering me.

The Witness: They are in Table 3.

The Trial Examiner: Exhibit 180?

The Witness: Exhibit 180.

By Mr. Keffer:

Q. They are separated again. That is the point, they are not weighted. You had them for each separate quadrant but not for the area as a whole?

A. No, I never did that.

Q. On the schedule which I hand to you and which you have already verified, you got it from the group of quadrants by simply dividing the acreage in the total group into the acre pounds?

A. Yes, you could arrive at it that way.

Q. Isn't that the only way you could?

A. Yes, if these calculations are right, you could.

Q. Of course, they are your calculations. You are pretty sure they are right?

A. I am talking about the totals.

Q. Sir?

A. I am talking about the totals.

Mr. Keffer: If the Examiner pleases, in order to have a basis for this calculation I am going to have the tabulation marked as—I don't care whether it is marked as an exhibit. It could be handed to the stenographer to be copied into the record. That is probably the better way to do it.

Mr. March: If there is any exhibit to go into the record that will be identified, we are going to place it in the record. This is the same line of cross examination we objected to a while ago. He even wants to go further. He wants another computation into the record. We wish to interpose an objection to it being placed in the record. It is not being done either in courts or in administrative procedure.

The witness then testified further with respect to the quadrants containing Canadian River's acreage, and there was identified through him and placed into the record the following data taken from the witness' working papers:

		Acres	Acre-Pounds 1935	1936	1937	1938	1939
Hartley	HA	32,906	14,113,298	14,112,147	14,047,499	13,952,964	13,928,532
Potter	I	57,588	24,176,000	23,961,000	23,815,000	23,582,000	23,196,000
	II	44,937	18,966,000	18,869,000	18,628,000	18,497,000	18,191,000
	III	33,389	14,198,000	13,985,000	13,938,000	13,847,000	13,607,000
Moore	I	62,173	23,819,359	23,364,975	23,115,452	22,704,031	22,108,761
	II	61,866	25,624,302	25,396,197	24,933,023	24,248,578	23,238,433
	III	56,614	24,212,903	24,061,291	24,005,464	23,878,600	23,574,156
Hutchinson	III	53,967	15,920,702	15,708,405	15,259,718	15,010,397	14,601,992
Carson	IV	40,251	16,409,700	16,175,600	15,929,200	15,472,200	15,160,100
		443,691	177,440,264	175,633,615	173,671,356	171,192,770	167,605,974

The witness stated that the acre pound factor for each quadrant was determined by taking into account not only the production and pressure drop, but by taking into account also the same data for all surrounding quadrants.

The witness stated that the average weighted pressure of all of the quadrants in which Canadian has acreage may be obtained by dividing the total acreage into the total acre pounds, and that if this is done, assuming the calculation is made correctly, the total weighted pressure for 1936 would be 395.85 pounds; for 1937, 391.42 pounds; for 1938, 385.84 pounds; and for 1939, 377.75 pounds, which would show a pressure drop as follows:

1935-1936	4.07
1936-1937	4.43
1937-1938	5.58
1938-1939	8.09

The witness further testified (Vol. 59, pp. 8418-8429) as follows:

Q. For 1937, making the same calculation, it gives you a decline of 4.43 and for 1938 it gives you a decline of 5.58, and for 1939 it gives you a decline of 8.09. Those are based upon the calculations which the record will show. Assuming that those are correct calculations, Mr. Hammer, is it not true that the pressure decline in the Canadian River area is accelerating also?

Mr. March: I object to that question, if the Examiner pleases. Whatever conclusion can be drawn from that, the Examiner can draw it. Counsel not only wants him to go along with the computation but he wants him to make a conclusion, draw a conclusion from those computations and that is additional grounds for objection upon our part.

The Trial Examiner: Objection overruled.

By Mr. Keffer:

Q. It isn't a conclusion in the true sense of the word. You do have accelerated pressure drop, don't you?

A. The figures indicate that.

Q. And plotting that for each year, letting your coordinate points represent each year during that period, it

shows a very decided acceleration in the decline of that pressure?

A. You can take a group of points of that type and it all depends upon the subdivision that you make on your co-ordinate paper. You can draw any sort of a picture you want to.

Q. You can do that on yours, too, can't you?

A. You can't, no.

Q. All right, now, Mr. Hammer—

A. You only have one factor to consider the way you draw those curves—pressure and years—

Q. Pressure and years are two different factors. I don't see any use of discussing that curve. You have said that it wasn't indicated, haven't you?

A. Those figures you put in indicated it.

Q. Don't you know it is true?

A. I haven't checked those figures.

Q. Don't you know it is true anyway?

A. No, I do not know it isn't true.

Q. Don't you know anything about this after a year and a half work on it?

A. Yes, sir.

Mr. March: I object to the question. This witness has been harangued enough, if the Examiner pleases. A remark like that in the record is not justified and I ask that it be stricken.

Mr. Keffer: I will agree with counsel.

The Trial Examiner: He has agreed to strike it.

By Mr. Keffer:

Q Now, let me ask you a very simple question. The increase in pressure drop from 1938 to 1939 was almost sixty per cent greater than it was from 1937 to 1938, isn't it?

A. I don't know. I haven't calculated it.

Q. Look at it. Assuming my figures are correct, then, it is about sixty per cent greater.

A. I will say that it is, but it doesn't in my opinion mean anything.

Q. All right, it does mean something if the production did not increase anything like sixty per cent during that period, doesn't it?

A. No, I don't think it does.

Q. Well, why doesn't it? Suppose the production did not increase at all, yet your pressure drop did increase sixty per cent, would that mean anything to you?

A. All right. A curve of that type doesn't mean anything unless you bring into it the volume of gas removed.

Q. That's just what I'm doing, and you won't let me.

A. No, you aren't, you're plotting pressures against time.

Q. But now we are bringing production in, Mr. Hammer. Listen to me. That was the basis of the question that I asked you, the production angle. Now, if you have a decline in one year from 1937 to 1938 of 5.58 pounds and then you have a decline from 1938 to 1939 of 8.09 pounds, and if you had no increase in production, if you have had the same production figure for each year, then would a decline like that mean anything to you? That was my question. You have got the production in it.

A. Well, there are so many factors the way you have put that figure, it would have to be checked. You have made a statement there as far as I see it, Mr. Keffer, that there actually has not been any increase in withdrawals from time to time. I don't—I can't look at a thing like that and check it here on the witness-stand when you are talking about—

Q. Now, listen, Mr. Hammer, and listen to this question carefully and see if you can't get it. Let me repeat it again. We have a production decline from 1937 to 1938 of 5.58 pounds. We have a production decline in the same area from 1938 to 1939 of 8.09 pounds. Now, assuming—

Mr. Spencer: You meant "pressure decline" instead of "production decline"?

Mr. Keffer: Yes, that's right.

Q. Now, assuming that the actual production for each of those periods was the same, would that increase in pressure decline mean anything to you. Now, that's a simple question. See if you can't answer that.

A. If the production remained constant?

Q. If the production remained constant for each year.

A. It would indicate something, yes.

Q. All right, what would it indicate?

A. It would indicate greater withdrawals from—

Q. If the production was constant.

A. You didn't let me finish.

Q. All right.

A. That's just one of the things I've been talking about. Locally around the various areas we took into consideration just the thing that you are talking about there, that there was local gas movement from one area to the other.

Q. And we have included all these areas, remember that.

A. No.

Q. All areas in which Canadian River had a foot of acreage is included.

The Trial Examiner: You are speaking, Mr. Keffer, of this calculation which you have just recently gone through?

Mr. Keffer: Yes, sir, that's right. That was the average weighted pressure and the pressure declines from year to year in the group of quadrants in which Canadian River has acreage.

The Witness: Well, let me say this, that I don't believe that that method that you have used there, Mr. Keffer, is—

By Mr. Keffer:

Q. Mr. Hammer, can't you answer a simple question just once in five days?

A. Yes, if I'd answer them the way you want me to.

Q. Answer it some way. Just answer it.

A. All right, I was going to answer it. What I started to say, that drawing this curve as you have drawn it and using the data as you have figured it out, why, the curve is probably—it probably indicates a drop from year to year there. That is to be expected. You get a drop, but the question of the increment of increase of drop this curve doesn't represent.

Q. Just forget about the curve and go back and answer my question some way. Let's dispose of the question by having an answer to it.

The Trial Examiner: Mr. Hammer, he has gotten away from the curve now. Read the last question, please, Mr. Reporter.

(The question referred to was read by the reporter, as set forth above.)

By Mr. Keffer:

Q. Now, will you please answer that question?

A. Well, assuming that your calculations are correct, it would mean an increase in gas taken out of the ground other than the metered gas that we used.

Q. Would it indicate depletion, an increase in depletion at the same volume of production?

A. I don't figure that way, but if you want to figure it that way, it would.

Q. Answer yes or no. Would it or would it not?

A. I don't think you can figure depletion from one year to another. If you want to figure it that way, yes it would.

Q. Could it possibly mean by any stretch of the imagination, Mr. Hammer, that maybe some of the gas going out of those areas underground is a result of drainage?

A. Well, it could mean part that and it could mean something else. In our case if could mean some of the unaccounted for gas; that is, gas other than metered gas that we didn't take into consideration.

Q. You mean they lost all that in blowing wells?

A. No, I didn't say that. I said some of it.

Q. All right.

A. Now, let me finish my answer. There are some wells that I remember in that territory where they were drilled too deep and unless they have been repaired, those nonproductive sands and gravels down in the granite wash have been acting as thief sands to take some of that gas out. How much, I don't know, and no one else knows, but they are factors to consider.

Q. All right, now, Mr. Hammer, you are reaching out, grasping at straws, aren't you?

A. No, I am not grasping at any straws, I am telling you facts.

Q. Isn't the most plausible explanation, the only one that has any reason back of it at all, that in addition to the gas that is coming out through your well bores you are also losing gas by migration from that area, from that group of quadrants to another which has resulted in a larger pressure drop than the same volume of gas had indicated theretofore?

A. I at no time since I have been on this witness-stand denied that there was some local *draiage*. I don't deny it now.

Q. Well, then, I take it that you have finally answered that in all probability it is caused by drainage, is that correct?

A. A part of it could be. I have explained that there are reasons—

Q. How much of it do you think would be caused by drainage?

A. I have no idea, but the causes are there that could account for it.

Q. Well, do you think that the operators in that field are so extravagant that they waste anything like that much gas in blowing wells, for example, which is not metered?

A. I have no idea of what they do in that field on wasted gas.

Q. Let me ask you another thing: Look at your map over here. Could that not also result, as your lower pressures eat back into the higher pressure areas and you get into high pressure areas that were high the year before but are lean, don't have much gas in them, and where a little gas will drop the pressure more than it did back here in the more productive areas? Now, couldn't that have happened?

A. Read that question. I don't think I understood what you are trying to get at.

(The question referred to was read by the reporter as set forth above.)

The Witness: There are so many angles to that question—you are trying, as I see the question, Mr. Keffer, to bring into that question several factors such as drainage and permeability and what-not.

By Mr. Keffer:

Q. No, just one simple factor, whether or not a given production of gas will result in a higher pressure drop in a lean area than it will in a much more productive area. That is all the element there is to that.

The Trial Examiner: That is your question, now?

Mr. Keffer: Yes, it could be stated that way. Really that would hardly be an intelligent question within itself. You would have to read the two together. It is rather an explanation of my former question.

The Witness: What was that question?

Mr. Keffer: It has been suggested that I restate the question.

Q. That larger pressure drop which we have been discussing which occurred in 1938 and 1939 could have been influenced to some degree by the fact that as pressures eat back further and further and further, that is, lower pressures eat back further and further into a high pressure area and began reducing the pressures in areas in which much gas is not to be found, that that fact within itself would have a tendency to reduce the pressures with the same volume of production, is that not correct? It is somewhat in the nature of a statement. It is hard to state it otherwise.

Mr. March: Assuming, Mr. Keffer, of course, that they were eating back.

Mr. Keffer: Well, his own map shows that.

Mr. March: Well, that is a conclusion on your part.

Mr. Keffer: No, that's his conclusion. He made the map, I didn't.

The Witness: Well, I don't know. I am really honest when I say that I can't figure out how to answer that question because I don't understand it.

Mr. Keffer: Well, just strike the question, then. I'm too tired to take any more time on it.

Q. Now, Mr. Hammer, if you have this accelerated drop on Canadian River's acreage which has increased practically sixty per cent from 1938 to 1939 as compared to 1937 to 1938 and which has been increasing every year over the period, would you or would you not expect that acceleration in decline to continue into the future?

A. I have stated previously I do not know what is going to happen in the future. If present conditions continue to exist as they are now, I wouldn't anticipate that it would

materially increase. I would anticipate that it might decrease. I am not going to predict what is going to happen.

Q. What could happen that would cause it to decrease?

A. Well, they might quit drawing so much gas out of that territory.

Q. I am assuming the same volume of production to make it easy for you to answer.

A. Well, even then, not on one year's history, I wouldn't assume any such thing.

Q. I know, but you have a continuous decline for the entire period that you studied.

A. I'll tell you what I'll do, I'll agree to this maybe, that it is a whole lot closer if you would go back over all of your years and figure out what the increment of increase is rather than to take just one year, why, we might be getting closer together, but to take just one year I wouldn't agree to that at all because it isn't fair.

Q. One year doesn't mean anything, I take it.

A. Not when you have a life history of several more years, no.

Q. All right, does five years mean anything?

A. Yes, it means more.

Q. That's what you took.

A. It means more, that's true.

Q. Yet you have a curve that gets a little more sloping each year, each year during that period.

A. The way you have drawn it, that is true.

Q. And it would be that way if you drew it, wouldn't it?

A. Well, I don't think I would draw a curve like this.

Q. No, you wouldn't. You wouldn't draw the curve as it actually happened. You would draw a straight line across there which shouldn't be a straight line.

A. I would draw a curve, using the data necessary.

The Trial Examiner: I think the record is certainly full of that, Mr. Keffer.

Mr. Keffer: I think it is, too. I wonder if we might take a short recess.

The witness stated that although he had used the word "academic" with respect to his fieldwide estimate, there was nothing academic about it in so far as his estimate was

concerned but it was a real figure, and it was his thought that its relationship to the reserves of the Canadian River Gas Company might be largely academic.

The witness had made some references to a 73-year life for the reserves of Canadian, but the figure was used only in an illustrative manner and it was not his conclusion as to the life of Canadian River's reserves because he didn't know what would come in the future.

He was then asked the following questions:

"Q. What is your definite conclusion?

A. I haven't arrived at any.

Q. You just don't know how long it is going to last?

A. All I have attempted to do in this whole thing is to arrive at a reserve beneath the Canadian River acreage.

The Trial Examiner: As of—

The Witness: As of August 1st, 1939.

Q. Do you mean to say in your testimony that the Canadian River will recover that entire figure which you set out there as its reserve as of that date?

A. That question is a question that isn't a question directly associated with an estimate of reserves.

Q. Oh, I'll grant you that, except this, that you have to consider those angles in making your estimate, don't you?

A. No; not in making an estimate of reserves.

Q. In other words, you didn't try to make an estimate of recoverable gas, but rather the gas that is in place there today?

A. That's right.

Q. Without any conclusion that you might recover that much gas or more than that, or what-not.

A. That's it. This whole reserve study, and a reserve study in any case is to arrive at the gas in place on a given date as near as you can.

Q. Well, then, your figure which you use of 3,645,213,000,000 cubic feet as of August 1, 1939 was not intended as a figure representing recoverable reserves, but rather remaining reserve in the ground as of that date?

A. That's right, remaining reserves down to 25 pounds well head gauge."

The witness had computed his reserves down to an assumed abandonment of 25 pounds gauge pressure at the well head, and for the purpose of illustrating the point, stated that the virgin pressure was 430 pounds and in calculating the remaining reserves to 25 pound abandonment he would simply subtract 25 from 430 and determine how much gas there was in place with 405 pounds pressure.

The witness stated that the 25 pound abandonment pressure utilized by him was not intended to be representative of the actual economic abandonment pressure because he did not know what the economics of the thing would be. It is his opinion that the proper abandonment pressure is an economic question and that it will be solved in the light of economic conditions and situations existing at the time the problem presents itself.

He had made no study of the economic situation that might prevail at that time.

The witness was then examined with respect to the matters mentioned in his original statement which tended, in his opinion, to make his estimate a minimum one. He stated that his estimate represented a minimum figure because the pressures of the wells in most cases were not permitted to build up to a normal pressure, but stated, on the other hand, that if the pressures of 1935, for example, were not entirely stabilized, and if the pressures for subsequent years were not entirely stabilized, then this would make no particular difference, but he didn't know whether the proportion of low pressure was any greater in one year than another. His premise assumed the pressures were O.K. in 1935, but began getting too low after that. The witness stated, however, that it might be true that the errors inherent in the pressures for each year might wash out, but he does not know precisely how the closed in pressures would vary from year to year. For example, if the pressures, as actually gauged, were low in 1935, he couldn't assume they might also be low in the same proportion for 1936, but if this were to be assumed, then the drop would be just the same and his estimate wouldn't be affected. He also stated there would be a tendency for the same

error in taking pressures to occur each year and that it would be fair to assume that some error would occur each year, but he couldn't say how much, but if the same error did occur each year, it would completely wash out, and that the overall pressure differential would be the same.

The witness further testified (Vol. 59, pp. 8447-8465) as follows:

Q. All right, now, let's go on to No. 3. Well, we'll take No. 2. You say you haven't considered unmetered gas that was wasted. Do you mean by that, gas used in blowing wells, in wells of that type?

A. Yes, only gas that was metered and reported to the Texas Railroad Commission.

Q. Yes. Now, I can understand very well how that—the fact that you did not consider that might give you a lower production per pound drop in pressure. That is quite true, but on the other side of that thing; if you had considered these sloping lines that we are talking about when you consider production against them, they might have been more slanting than they are, isn't that a fact?

A. No, that is not true.

Q. It isn't?

A. No, not at all.

Q. All right. One further question on that. The fact that you haven't considered it in making your estimates, also if you try to get field life by dividing into those estimates the total production, and you don't count this unmetered gas, that would have a tendency to give you a bigger figure for the life of the field, wouldn't it?

A. You mean if you had this wasted gas in your calculation?

Q. If you left it out of your calculations in the second place just as you did in the first place.

A. Well, now, let's see.

Q. All right, I'll give you a simple illustration on that. Your estimate—oh, we'll say in round figures—well, I don't like to use yours because we may get some confusion in the record—suppose your estimate was a trillion feet and suppose you had a billion feet per year of metered gas. A billion into a trillion goes a thousand times, doesn't it?

A. That's right.

Q. All right, that would give you a life of a thousand years, wouldn't it?

A. That's right.

Q. But if in addition to that billion feet of metered gas there was 250 million unmetered gas which you did not take into account, which if you had added to that metered gas to divide into our reserves would give you a life of, instead of a thousand years, about 800, wouldn't it?

A. No.

Q. Why wouldn't it?

A. Because it wouldn't. The more gas that you take into consideration when you utilize the decline method as against any given set of pressure drops, the greater will be your reserve.

Q. Oh, I understand thoroughly, but I was going to the next point. I was beyond that. When you have your reserves and you want to determine life by dividing into the reserves the annual withdrawals, but you take only the metered withdrawals and not the unmetered withdrawals, then that gives you a bigger figure for life than you would have gotten if you had added the unmetered gas to the metered gas and then divided. Now, that is perfectly obvious.

A. I see what you mean. In other words, you are getting to the point that if you utilized or if you knew all of the gas when you are figuring life—now, mind you, in figuring reserves it is quite a different thing from figuring your life.

Q. I appreciate that, yes.

A. If you knew all of the gas that had not been metered, it would have a tendency to give you a lesser life.

Q. That's right, so that again, figuring from those two angles, one sort of washes out the other, doesn't it?

A. No.

Q. Now, get me straight.

A. Not at all.

Q. I am talking from the standpoint of determination of life in years and not reserves.

A. I have stated a while ago and I will repeat again that in the estimation of a gas reserve of this type I did not take into consideration anything except to determine the amount of gas in place in the ground as of a given date.

[Further Testimony of the WITNESS HAMMER, continued.]

Q. I appreciate that, and that gave you a little lower reserve than you would have gotten if you had taken this other gas into account.

A. That's right.

Q. I understand that perfectly. Now, let's leave that and go over to the point where we are trying to determine life of the field; then, when we divide only metered production into the reserve figure, you would get a longer indicated life than you would get if you divided the metered gas plus unmetered gas into that reserve figure.

A. Yes, that's all right.

Q. Obviously.

A. I will agree with you on that.

Q. That is, from the standpoint—looking at it from the determination of the life of the field, then one certainly would have a tendency to wash out the other, wouldn't it?

A. Well, as I have said, I haven't made a study of the life of the field particularly.

Q. All right, then, we'll go on to the next one. Now, you say that the pressures were not calculated to reservoir conditions, but were well head gauge pressures. Well, I think I understand that, but after all, if you compute down to an abandonment point of 25 pounds well head pressure, why, that is just what it is. You started with a 430-pound well head pressure, didn't you?

A. Yes.

Q. You didn't compute that 430 pounds well head pressure back to reservoir pressure, did you?

A. No, I didn't calculate the reservoir pressure.

Q. And then that one washes out completely, doesn't it, because you started with a well head pressure, so you had to end up with a well head pressure.

A. The point there is, though, that by utilizing this 25 pounds in order to have that 25-pound abandonment pressure at your wells you necessarily have to have a differential pressure in undrilled areas as against where the wells are.

Q. I understand that.

A. Therefore, you do have a larger amount of gas than is indicated, assuming a 25-pound—

Q. That comes under 4. We are talking about No. 3. We haven't got to 4 yet.

A. Oh, I see. Read that question.

(The question referred to was read by the reporter, as set forth above.)

By Mr. Keffer:

Q. Isn't that right?

A. Yes. I started with 1 and ended up with 1, but we must consider that thing when we go on to 4.

Q. Well, I know, but we haven't got to 4 yet. 3 standing alone is not a good reason for a minimum estimate, is it, not a valid reason?

A. It is not particularly pertinent to the thing, anyway.

Q. Well, it just isn't any reason at all, getting right down to brass tacks on the thing.

A. I think I have answered it.

Q. The point is, I want the record to be clear on that. You didn't start with reservoir conditions in your estimate.

A. No.

Q. But you started with 430 pounds well head gauge pressure, as virgin.

A. As virgin, yes.

Q. Yes.

A. That's right.

Q. All right, now, if you had transported that 430-pound well head pressure to a reservoir pressure you would have gotten considerably more than 430 pounds in the reservoir, wouldn't you?

A. Oh, yes.

Q. And then if you would have come back and figured well head pressures in your calculation to get your drop in pressure, you would have a lot bigger drop than what you did have, wouldn't you, if you startted with reservoir pressures and then ended up with well head pressures, you would have a much bigger pressure drop than actually existed, wouldn't you?

A. If I had used reservoir pressures?

Q. Yes, as your starting point and then deducted from that your lower well head pressures taken at a later date, you would have had a much greater pressure differential, wouldn't you?

A. As between original field pressure.

Q. That's right, and the pressure at any given date later.

A. Yes, using well head pressures would give you a greater differential than it would if you used reservoir pressures.

Q. That's right, so as a matter of fact if you had gone back to reservoir conditions as your beginning point you would have had a lot smaller reserve than the one that you did as you calculated it, wouldn't you—very much smaller because you would have a much greater pressure drop?

A. Restate that for me, will you? Read it, please?

(The question referred to was read by the reporter as set forth above.)

The Witness: Well, let's see, we started with reservoir conditions.

By Mr. Keffer:

Q. That's right, and if we would end with reservoir conditions then it would wash out, wouldn't it?

A. That's right.

Q. But if you started with reservoir conditions and end with well head conditions, or pressures, it wouldn't wash out, would it?

A. But if you start with a well head condition of 430—

Q. And end up with a well head condition at whatever it is, 360 or 350 or what have you.

A. The two methods should almost parallel each other.

Q. That is it exactly. That is the whole point I have been trying to make; so reason 3 as to why your reserve estimate is a minimum one just goes completely out the window, doesn't it?

A. Well, we have to tie that in to 4: so let's go into 4 and then I'll answer it.

Q. We haven't come to 4. We'll take No. 5 and come back to 4. You say: "Consideration was given to the deviation from Boyle's law, but was not applied. Its utilization would have given a somewhat higher result."

Now, let me ask you this in connection with that: When you take into consideration deviation from Boyle's law,

must you not also consider your temperature factor and give consideration to that?

A. Yes.

Q. All right, you gave no consideration to temperature, did you, temperature variations from reservoir conditions and well head conditions?

A. Well, I know the difference between temperatures, while it does have a bearing, is so seldom used in a calculation of reserves unless you want to go down and calculate that reserve to reservoir conditions, at the well head that factor is such a variable that you would have to have a recording thermometer on them all the time to tell what they were.

Q. That is precisely correct. All right, but your failure to consider temperature deviations or corrections for temperature washes out your failure in effect to calculate deviation from Boyle's law; now, isn't that correct?

A. I wouldn't want to agree to that statement. I would want to check it if I possibly could. It is my opinion that it does not.

Q. It does not? Say your average pressure in the field in August 1939 was 332 pounds ,approximately,—331, plus—what is the deviation from Boyle's law at 331 pounds?

A. Well, I don't know that I could give you that offhand.

Q. All right, do you know what the difference in temperature would be of reservoir conditions and well head conditions if you adjusted for that?

A. Well, not offhand.

Q. Well, do you know this? Can you answer me this, Mr. Hammer? I am not going to spend much time on it. Can you tell me whether or not engineers and geologists generally consider that in this reservoir that failure to correct for temperature just about offsets failure to consider the deviation from Boyle's law?

A. Well, I wouldn't know what the general opinion is.

Q. Haven't you ever figured that out to find out just what the difference would be?

A. No, I never figured it out.

Q. All right. We'll go ahead. You don't know, then, for sure whether one would offset the other or not?

A. I doubt if they would.

Q. But to approximate it you—

A. I wouldn't even want to say that without—

Q. I thought you liked that word "approximate," and maybe you would use that one all right.

Let's come back to 4. Are you ready for 4?

A. Oh, I've been ready for a long time.

Q. All right, now, I don't understand you on 4 at all.

A. I didn't think you would.

Q. Tell me about it. Maybe we ought to get into the record. You say, giving an added reason in Paragraph 4, that "Utilizing a 25-pound abandonment pressure well head gauge, necessarily means a higher weighted pressure, because there would be no such well head pressure if there were no higher pressure at undrilled points. In other words, to have 25 pounds well head gauge pressures at abandonment, necessarily indicates a pressure differential between the face of the producing formation in the well as against undrilled areas."

I think that explains the thing.

Q. Well, let me ask you some questions, then. Now, you told me a while ago very definitely and very positively that when you figured this 25-pound abandonment pressure, that that represented what was left in the ground at 25 pounds, didn't you?

A. Well head abandonment.

Q. That's right, and you also figured—you took that 25 pounds from 430 and you had 405 pounds left, didn't you, to produce? Now, isn't that right?

A. Well, if you want to figure it back to original reservoir conditions, yes.

Q. All right, now you have produced 405 pounds, haven't you, when you get down to 25 pounds? You just said that.

A. Well, no. The point is that you are dealing here in one case with a well head pressure and there is a reserve left in the producing formation above that.

Q. I understand that. I am going to agree with you on that.

A. All right.

Q. But wait a minute, we aren't quite ready for that yet. Remember you have got a calculated figure here, haven't you?

A. Yes, that's right.

Q. And that figure is calculated down to 25 pounds abandonment on the theory that you have produced 405 pounds, down to that point, isn't it?

A. Yes, but you are overlooking the fact that there is still a lot of gas in that formation above 25 pounds.

Q. We are going to get to that in a minute. From the standpoint of your calculated figure, if you have produced 405 pounds, and that is what your figure is calculated upon, then from the standpoint of calculations, you have a 25-pound pressure straight across from the standpoint of your calculations, as a matter of fact. Now, isn't that true?

A. No.

Q. Now, tell me how on earth you can get any different result than that.

A. We are talking about a reserve in the ground.

Q. I know we are.

A. And in the other case we are talking about an abandonment pressure.

Q. That's right.

A. The two aren't synonymous at all and one is not dependent upon the other.

Q. Let's go over it again, Mr. Hammer. Remember we aren't going down three thousand feet under the ground and actually measuring this gas, are we? We are calculating it, aren't we, from the top of the ground?

A. That's right.

Q. All right. Now, the figures which you have when you assume a 25-pound abandonment, and you have said it a number of times, you calculate your production, your reserves, down to 25 pounds by taking 25 from 430 which was your virgin pressure and assuming, then, if you are going to produce to 25-pound abandonment, that you are going to produce 405 pounds and you make your calculations on that basis. Now, that's right, isn't it?

A. But you have got to consider that you have a lot of gas left in the ground when you get down to 25 pounds.

Q. Well, that reserve left in that, above your 25 pounds, is still a part of your reserve. I will agree with you on that.

Let's take another angle on that. If, then, you are going to leave some of that in there, you aren't going to produce 405 pounds. That would have to follow, wouldn't it?

A. No, it wouldn't have to follow at all.

Q. How on earth are you going to produce 405 pounds out of 430 pounds and have more than 25 pounds left? Now, you tell me that.

A. We are talking about a well head abandonment pressure.

Q. I know we are.

A. All right.

Q. That's the way we have figured always on well head abandonment.

A. I have said before and I repeat again that in order to have that you must have a lot of gas. The whole reservoir away from your wells must necessarily have a pressure above it. How much above it, I don't know and neither do you. All of the gas that is in that reservoir above the 25 pounds is still a part of your reserve.

Q. Surely. Is that all?

A. Yes, that's all there is to the question.

Q. All right, the only difference between you and me—we agree on the facts, Mr. Hammer, entirely so. I agree that for you to have 25 pounds well head pressure you have got to have a higher pressure back from that well, and that is what your argument is based upon, isn't it? I agree with you thoroughly on that.

A. All right.

Q. There isn't any question about that.

A. All right.

Q. The only difference between you and me—

A. You aren't assigning—the only difference between you and me is that you are not allowing or assigning any reserve to that reservoir above 25 pounds.

Q. Yes, I am. There is where you are wrong. We are right together until we get right down to the point of whether we add or whether we subtract. I say we ought to subtract and you say we ought to add. That is the only difference between us.

A. And I am not going to agree with you.

Q. I believe you will. I still don't think you say it. I made a promise a while ago and I am going to live up to it, anyway.

Now, here, let that very true figure represent your reservoir—is that all right, Mr. March?

Now, you are going to produce that. You are going to produce 405 pounds of that, aren't you?

A. No, —now, wait a minute.

Q. Now, wait, don't you change on me, you have said that too many times.

A. Well, I have been referring back to well head, to what you would get at 25-pounds abandonment, well head.

Q. That's right.

A. Now you come along here with a picture illustrating a reservoir, or attempting to illustrate a reservoir, and the condition is not synonymous at all.

Q. Well, now, listen to me, Mr. Hammer. Please don't back up on me this late in the game. You have said two or three times that in your calculated figure the figure which you used in calculating your reserves down to 25-pound abandonment, that you used the figure of 405 pounds that would be produced and made your calculations on that basis. Now, that is a fact, isn't it?

A. Yes.

Q. And you couldn't do it any other way, could you?

A. But—

Q. Now, wait just a minute. Give me this indulgence here. Now, from a calculated standpoint that is what we are talking about. You calculated 405 pounds produced; so from a calculated standpoint you couldn't have more than 25 pounds left because you only started with 430. Now, isn't that just as simple as it can be stated?

A. No, that is not true at all. You are confusing reservoir conditions with well head conditions.

Mr. March: Mr. Keffer, haven't you made a mistake?

Mr. Keffer: No, I haven't.

Mr. March: You have deducted the 25 pounds from 430 instead of the present weighted pressure.

Mr. Keffer: How's that?

Mr. March: You have deducted it from—didn't you do this? Didn't you deduct it from 430 instead of your present weighted pressure?

Mr. Keffer: I didn't deduct from any sort of weighted pressure. I am assuming virgin pressure.

Mr. March: Which the witness has not done for this purpose.

By Mr. Keffer:

Q. Then take your present weighted pressure and deduct 25 pounds from that and tell me what you figured it on. If Mr. March would rather have it that way, we'll do it that way.

Mr. March: Weighted pressure.

Mr. Keffer: Give me that figure.

Mr. March: You are asking the questions. You can find out what it is.

Mr. Keffer: How do you know it is 430, then?

Mr. March: I know it isn't 430.

Mr. Keffer: All right, 333, we'll say, approximately.

Q. We'll say 333 to start with and you are going to produce it down to what?

A. 25 pounds well head pressure.

Q. You are going to produce how much? —let's see 5 from 5 is nothing, 2 from 3 is 1—you are going to produce 310 pounds, aren't you? I used 335. That's all right, that's near enough.

A. You are going to use that pressure?

Q. That's right, and from the standpoint of your calculation you are just going to have 25 pounds in your reservoir from the standpoint of calculations, arithmetic, I am talking. That's what you are going to have.

A. I am talking about reserve.

Q. That is right, from the standpoint of your calculation you are just going to have 25 pounds in your reservoir?

A. I am talking about reserve.

Q. All right. In that reserve you are going to have 25 pounds less?

A. No, that isn't true at all.

Q. All right, I will go ahead.

It is going to hustle me to make this thing good, but I am going to make this stand. If you have 25 pounds left in the reservoir as a calculated figure, yet actually you have

more than that because the pressure is higher between wells than it is at the well head, then the natural result of that it you have got to make some allowance from that and you have to deduct something from your original reserve because you have something there you are never going to produce. It is subtraction and not addition?

A. No.

Q. All right, that is all. I am not going to argue that any longer. It is too obvious.

Witness Hammer further testified on redirect examination, Vol. 60, pp. 8467-8530, inclusive, as follows:

Q. Since you mentioned here Wheeler County, Quadrant 1, I will ask you to turn to your Exhibit 180, Table 1. I believe it was Hartley County 1 you had a particular discussion in regard to.

Now, there was some indication during the cross examination by counsel that you had in this exhibit erroneously added accumulated production to accumulated production to get your figures there, 6,785, for 1939, in Column G, Accumulated Production.

Now—in other words, instead of adding up your production you just added accumulated production to accumulated production to get your erroneous answer here. It ran around something like sixteen million, I think, instead of what you have here. Now, you didn't do that at all, did you, Mr. Hammer?

A. Why, no. That was brought about by the confusion in attempting to get figures together hurriedly. The actual figures used were the figures that are here on Table 1 in Exhibit 180, in Column G, and those are accumulated figures from year to year.

Q. Yes, in order to get that figure you didn't add up your 5,000 and 3,000 and your 7,000—I beg your pardon, your 5 million, your 3 million and your 793,000?

A. No, not at all.

Q. And the exhibit is absolutely correct in that regard?

A. The exhibit is correct in that regard.

Q. The only difficulty in the cross examination, as I understand it, was the fact that you took off of your working papers rather absentmindedly the figures and added them up?

A. That's right. Naturally, I had to do some of that stuff hurriedly and that error was made, but the correct figures used are those figures shown under Hartley, under Column G of Table 1, Exhibit 180.

Q. Now, that was the only direct implication made with regard to that in this exhibit—

Mr. Keffer: If the Examiner please, I don't know what Mr. March is talking about when he says "implications." I think the record is clear that the error was made. I called it to Mr. Hammer's attention. It was just an erroneous calculation, is all it was.

Mr. March: There was quite a point made of it at the time that the exhibit was wrong.

Mr. Keffer: Don't pick out implications where there were none.

Mr. March: If none was intended, I will assume there were none.

Q. All of this came up over a question as to why you left Wheeler County out down here, Quadrant 1. Then the controversy came up in regard to that in an attempt to show that the production in Wheeler County 1 was higher than Hartley County quadrant here (indicating), and therefore, in the same line of reasoning you should have left out your Hartley County quadrant. That is my understanding as to why this arose. Is that your understanding?

A. It is difficult for me to say what was had in mind. The idea I got was that I had deliberately left that out for an ulterior reason.

Q. Yes. That was your impression, and it was my impression, too, that the reason you left out your Wheeler County 1 was that in order to leave out Wheeler County 1 it would necessarily in doing that increase your estimate of reserve?

A. That was the implication as I got it.

Q. And a great deal of argument as I recall followed and you said that was not true?

A. That's right.

Mr. Spencer: May I interrupt you just a moment, Mr. March?

Mr. March: Yes.

Mr. Spencer: Only for the purpose of suggesting this, that the illustrative quadrants used were for the purpose of analyzing Wheeler County Quadrant No. 1 were Gray County Quadrants 1 and 2, and not Hartley.

Mr. March: I am coming to Gray 1 and 2 in a minute. Hartley was mentioned in that connection, too. The record will so show.

Q. Now, I believe that you stated as your principal reason for leaving out Wheeler County 1 was because you didn't have the production data on that county accurately and reliably.

A. I think it was because of inadequate production data.

Q. You went ahead and gave other reasons but that was the principal reason?

A. That was largely and principally reason for leaving out Wheeler County, that is true.

Q. You recall the other night going over your working papers with me and we noted a very significant thing on those working papers. Will you turn to Wheeler County 1? Now, have your turned to Wheeler County 1 in your working sheets here?

A. That's right.

Q. Now, I will ask you if that is your handwriting on that work sheet?

A. It is not.

Q. That is one of your assistant's handwriting?

A. That's right.

Q. Now, I will ask you what is the notation above—below the compilation on that work sheet?

A. The notation says: "Insufficient production data," and down in the corner, "Not used."

Mr. Spencer: Hadn't we ought to identify that?

Mr. March: I am going to.

Mr. Spencer: You should do that before reading it in.

Mr. March: The witness is identifying it first, and then I will identify it.

Mr. Examiner, I would like to have identified for the record the work sheet, Wheeler County 1—Wheeler Quadrant 1, as Exhibit No.—

The Trial Examiner: Do you wish to have it marked as an exhibit, Mr. March?

Mr. March: Yes. The reason I do that is because any court of law would recognize that a notation made in the course of business in the compilation of an exhibit would be the best evidence of the intentions involved.

The Trial Examiner: It will be marked for identification as Exhibit 191.

(Exhibit 191, Witness Hammer, marked for identification.)

Mr. March: I will have to secure copies of this.

The Trial Examiner: What would you title that sheet, Mr. March?

Mr. March: I would entitle it "Work Sheet, Wheeler Quadrant 1, Texas Panhandle Field."

Q. It was brought out in the record here and I believe you agreed in the record here that by using Wheeler County 1—by not using Wheeler Quadrant 1 you increased your estimate of reserves?

A. It showed an increase above that which would have been if I had used Quadrant 1.

Q. A slight increase as compared with the total?

A. That's right.

Mr. Spencer: Excuse me, Mr. March, you didn't understand me before. If you are going to have it identified and if it is going in the record, why not identify the assistant that made the notation at this time?

Mr. March: This witness' assistants that made these notations are in Washington. They are nothing more or less than Mr. Hammer's assistants and a man when he prepares an exhibit has a right to have assistants working under his direction. Every exhibit which the companies have offered here—Mr. Rhodes' exhibit—none of those working papers are in his handwriting. This man had these working papers made in Washington under his supervision. He couldn't make every notation on there.

Mr. Spencer: Granted. All I am asking you is the name of the assistant that made the notation.

Mr. March: Well, I'll give you that.

Mr. Spencer: I want it in the record. That's what I said five minutes ago.

Mr. March: Before I do that—I don't want to be diverted on this point here:

Q. As I said, Mr. Hammer, as you recall, we agreed that by excluding Wheeler Quadrant 1 you slightly increased your estimate of reserves by the pressure decline method?

A. That's true.

Q. Now, there was a great deal of argument that the production in Gray Counties 1 and 2 was slightly less than Wheeler County 1, and then why didn't you take out Wheeler Counties—Gray Counties 1 and 2? Well, now, if you had eliminated Gray County Quadrants 1 and 2, would not that have likewise increased your estimate of reserves?

A. Yes, it would have, on the same principle.

Q. On the same principle?

A. That's right.

Q. And if you had eliminated Hartley quadrant over here it would likewise have increased your estimate of reserves?

A. That's right, for the area considered. In each case, for the area considered.

Q. And you felt that you had here in Wheeler County a unique situatron in the entire field, Wheeler County, Quadrant 1?

A. Yes, it seems that way to me, that's right.

Q. And in your best judgment it could very well be left out in your estimate of reserves?

A. It was a matter of judgment and I felt that way about it.

Q. In other words, that illustrates the point that when you spread this estimate of reserves out over some of these not so productive acreages it has the general effect of decreasing your estimate of reserves, if anything?

A. That's right, because you have taken more acres into consideration.

Q. That's right. In any case, the thing is weighted out, so that when you weight your really productive acreage in with your less productive acreage, the whole thing weights

itself out and gives a fair estimate of the reserves for the entire area?

A. That's right.

Q. Now, Mr. Hammer, there has been some indication here during your cross examination here that you have been coached here from the sidelines. Was this exhibit prepared by you and under your direct supervision?

A. Absolutely.

Q. And the persons working under your supervision were all of lower grade than yourself?

A. Well, that term—

Q. In the classified service of the Federal Power Commission?

A. That's right.

Q. And will you indicate the individuals as near as possible from your recollection who assisted you in this project?

A. Well, do you want me to name all of them?

Q. All of them you can remember, yes.

A. There were A. R. Algier, an associate engineer; Fred Grote—I don't remember his rating—

Q. You don't have to give the titles.

A. Jack Dougherty; Charles Pettingall, and in the compilation of data up to the time when we started the actual estimate of reserves, Mr. H. F. Stevens helped us assemble and get the data together. That's all I can remember.

The Trial Examiner: The same Mr. Stevens that has heretofore testified in this proceeding?

The Witness: That's right. That is all I recall at the moment.

By Mr. March:

Q. Mr. Stevens was an associate of yours in general in this work?

A. In general, that is right.

Q. He is the only person in this hearing room that had anything whatsoever either direct or indirectly to do with this job?

A. That's right.

Q. Besides yourself?

A. That's right.

Q. And when it came right down to making decisions as to how this thing was to be put up, the method employed

and the way it was employed and those decisions, those were made by you?

A. They were my decisions entirely.

Mr. Spencer: Are you all through with the assistants, now, Mr. March?

Mr. March: I am getting to this thing that you wanted.

Mr. Spencer: All right.

Mr. March: I don't want to rush things here.

Mr. Spencer: The only reason I am interjecting is, if the questions and answers with reference to notations on that sheet of working paper relating to Wheeler County, Quadrant No. 1, is not connected with the party that made it, so we can cross examine him, I want to move at the proper time here to strike both questions and answers. That is why I kept interrupting.

Mr. March: You can make your motion at the proper time and we can argue it then.

Mr. Spencer: It was probably proper right after it was done, only I am just waiting.

By Mr. March:

Q. Do you know whose handwriting that is, Mr. Hammer, in the exhibit which has been marked for identification as Exhibit No. 191?

A. To the best of my memory and because it has the initials up here in the corner "C.E.P.," I believe that it is Charles Pettingall's handwriting.

Mr. Spencer: I didn't get that name, Mr. Hammer.

The Witness: Pettingall.

Mr. March: Does that meet with your approval, Mr. Spencer?

Mr. Spencer: Yes. I would like to know what position he occupies or did occupy when he made the notation.

The Witness: I don't recall what his classification is.

By Mr. March:

Q. He was working, though, under your supervision?

A. That's right.

Q. And you did not use Wheeler County Quadrant 1 in your estimate of reserves?

A. That's right.

Q. It was not used in connection with this Exhibit 180 and 179?

A. Well, that is true as far as Exhibit 180 is concerned. In the preparation of 179, why, naturally we isobarred the area. That was the first job, but in 180 we didn't use it.

Q. And you didn't use it in your estimate of reserves?

A. That's true.

Q. You left it out?

A. That is right.

Q. Now, Mr. Hammer, there was quite a bit of discussion here about some cylinder diagrams that had been marked for identification as Exhibit 189. Will you turn to that sheet, prepared by Mr. Hughes?

Now, say we withdraw, as Mr. Keffer had you do, 15,000 from Container No. A, and make your computation as it should be made from there, as you think it should be made, and explain them.

A. This is the problem where you withdraw gas from Cylinder A only?

Mr. Spencer: Which exhibit would that be tied into, Mr. Hammer?

Mr. Lange: 189.

The Witness: That is right. That is the problem that you asked about where you draw from one cylinder only?

By Mr. March:

Q. Yes, sir. I want you to compute your original reserves.

A. Well, if you take the three cylinders, Cylinder A having 30,000 cubic feet; Cylinder B, 20,000, and Cylinder C, 10,000 cubic feet, and you withdraw 15,000 cubic feet out of Cylinder A, you would reduce the pressure from 400 pounds to 200 pounds. Then in order to calculate that back and take into consideration all three cylinders it would be necessary to weight the pressures against the volumes, having in mind that Cylinder A after the withdrawals still

contains 30,000 cubic feet, but at a reduced pressure. You would weight the problem as follows:

30,000 cubic feet times 200 pounds remaining pressure would give 6,000 Mcf. 20,000 cubic feet at 400 pounds pressure would give 8,000 Mcf., and 10,000 cubic feet of gas at 400 pounds pressure would give 4,000 Mcf., or a total of 18,000 Mcf. Then if you calculate that 18,000 Mcf., if you take that and divide it by the 60,000 feet of total gas, you will get a weighted average pressure of 300 pounds. You must bear in mind that the total volume has been reduced from 60,000 cubic feet to 45,000 cubic feet, or 15 over 60, or 15 divided by 60, is one-fourth; also, that the pressure has been reduced from 400 pounds to 300 pounds or 100 divided by 400, or one-fourth. Therefore, the proportion of gas taken out is equal to the proportion of gas—the proportion of pressure taken out, which is equivalent and proves Boyle's law, and, furthermore,—or on a pound loss basis, if you will divide 15,000 cubic feet by 100 pounds loss you will get 150 cubic feet per pound in decline. Then if you will multiply that 150 cubic feet by the pounds in decline you will get 60,000 cubic feet, or the original gas in all three containers.

Q. That is assuming that they are all three inter-connected?

A. That is right.

Q. But that would not satisfy Mr. Keffer. He has another hurdle for you to jump here. That is this: As a matter of fact, that works out, as I understand it—I want to get it straight here first. What you have done is to weight pressures both as to area and content?

A. That's right.

Q. And when you do that you get the right answer?

A. That's right.

Q. But Mr. Keffer would say that the Panhandle field is—you don't have an equilibrium pressure there and these three containers here—and your inter-connected three containers and your pressures are allowed to equalize and you don't have in the Panhandle field—you do not have strictly from Boyle's law standpoint an equilibrium pressure, do you?

A. Not entirely so, no.

Q. In other words, if you secured an equilibrium pressure in the Panhandle field you would have to shut the whole field down for an indefinite period of time?

A. That's right.

Q. And let the pressure equalize?

A. That's right.

Q. And that is both impossible and impractical?

A. Well, under existing conditions that would never be done.

Q. Yes, so you had used the figure which was equivalent to the equilibrium pressure and which will give you substantially the same result, did you not?

A. I used the figure that was the closest approach possible to arrive at the equilibrium pressure, in my opinion.

Q. And what was that?

A. That was the preparation of these maps on isobars of ten-pound intervals and if we had been able to take them on down to five-pound or even on down to one pound, we would have very closely or more closely approached an equilibrium pressure.

Q. In other words, you had the weighted average pressure, as I understand it?

A. That's right.

Q. And the way you have applied that and weighted the whole thing out over your area here, although it is not a perfect answer, it is your opinion that it gives you an answer that for all practical purposes is the correct answer?

A. That is right.

Q. Since you mentioned these 10-pound isobars that you used, will you explain the advantages of using a 10-pound isobar over a 50-pound isobar or a 20-pound isobar?

A. Well, that's just what I had in mind a moment ago. The smaller pound interval you use the more closely you can approach the proper answer. Now, if you took and used 20-pound isobars there are local and sometimes relatively large areas of pressure between that, where you draw a 10 and 20, which would indicate on your ten but which would not show up or be indicated at all if you used 20 or larger.

Q. In other words, when you go down on your isobars to smaller intervals you get a more correct answer?

A. You get a better picture of the areal distribution of pressure.

Q. As a matter of fact; in this exhibit here, by using 10-pound isobars you go further as far as you know in this refinement than anyone else that you know of?

A. I think I have gone farther. I don't know of anyone else that has ever used 10-pound isobar intervals.

Q. What does the Railroad Commission use?

A. I think ordinarily they have used 50 pounds.

Q. Now, since we are on this isobar business, this 10-pound interval, you will recall that Mr. Keffer went at great lengths here to recite to you these pressures beginning at 200 pounds and going up to 400 pounds, at 10-pound intervals. He went over a whole list there. For example, he said from 200 to 210 and from 210 to 220 and right on up the line, and he attempted to show, as you will recall, that 400-pound pressures had just about twice as much weight as the 200-pound pressures.

A. Yes, I recall that.

Q. Assuming all the pressures there in one isobar. Now, as a matter of fact, Mr. Hammer, is this statement not true? If it is not true I want you to tell me.

Mr. Keffer: Just ask the witness a question.

Mr. March: I will ask the witness the questions as I see fit, unless the Examiner rules otherwise.

Mr. Keffer: Mr. Examiner, Mr. March has no right to lead the witness.

Mr. March: I don't have to lead the witness. There is no rule of evidence in the court that I can't lead the witness to a certain extent on redirect.

The Trial Examiner: He is your own witness, Mr. March. However, I will say—

Mr. March: Well, go ahead, make your ruling.

The Trial Examiner: May I rule now?

Mr. March: Yes.

The Trial Examiner: Let me say this, that so far as your leading questions are concerned, the witness is a responsible witness and I don't feel that it is harmful, and

perhaps it will expedite the hearing, and I am sure that Mr. Hammer appreciates the obligation of his oath.

However, I think, Mr. March, that you should bear that in mind and when it is at all possible to let the witness give the facts in the case, and I think you should proceed on that basis. I am not going—

Mr. March: Mr. Examiner, thus far this has been the only question that has been objected to, and it doesn't make any difference how strict the rules are applied in regard to us, we will not lead the witness directly or indirectly in this regard if the Examiner feels that way about it.

The Trial Examiner: I haven't said you could not lead the witness, Mr. March.

By Mr. March:

Q. What have you got to say about that, Mr. Hammer?

A. About that question of 200 and 400 pounds?

Q. That's right.

A. I think the best way to illustrate and define that situation is to state that in any case a segment having 400 pounds pressure considered in that light alone would contribute twice as much to the total factors as would the 200 pounds, but that each of the segments contribute equally to the average and that would hold true of any *infinitecimal* amount of segments.

Q. In other words, it would be likened to a scale, when balanced out it would level itself off?

A. That's right.

Q. Mr. Hammer, there has been some question raised as to whether or not the method which you employed here in estimating reserves has ever been employed before.

A. That question was asked me.

Q. Yes. You recall first that there was a great deal of questioning, though, in regard to the porosity pay thickness method of estimating reserves and you recall that the first question was asked you as to whether or not you recalled an estimate made by C. Max Bauer.

A. C. Max Bauer.

Q. Around 1931 and 1932, I forget which it was, and you said you did, did you not?

Mr. Keffer: Just a moment, Mr. March. Mr. Hammer volunteered the statement about Max Bauer.

Mr. March: You asked him first as to whether or not he knew of any estimates being made by the porosity thickness method in the early days and he answered the question.

Mr. Keffer: He said he understood that Max Bauer made one.

Mr. March: You asked the question and he answered it.

Mr. Keffer: Just a moment, that question was based upon the early porosity thickness method, or was it an estimate?

Mr. March: You can have a chance with the witness on recross. You can ask him about that on recross examination.

Mr. Keffer: I think it was on an early field estimate, regardless of the manner employed to make the estimate. That is rather my definite recollection of it. I could be wrong about it.

Mr. March: The record will speak for itself in that regard.

Q. You do recall a discussion about it?

A. Yes.

Q. You do recall quite a number of questions as to the soundness of the porosity sand thickness method in estimating reserves?

A. That's right.

Q. And I believe your opinion was that in regard to that—

A. That as far as the Texas Panhandle field is concerned it would give an erroneous answer and it really was not applicable in my opinion to an estimation of reserves in that field.

Q. Because you couldn't get adequate cores?

A. Because you couldn't determine the porosity adequately.

Q. You recall thereafter the question was asked you as to any estimate of reserves which had been made previously in which your method was employed or any portion of your method was employed?

Mr. Keffer: I never asked any such question as that.

Mr. March: I suspected Mr. Keffer would raise up and object to this, so I just got the record out here.

Mr. Keffer: All right.

Mr. March: So I want to read exactly what happened.

Mr. Keffer: You read just exactly what happened.

Mr. March: I will read the record on Page 7950. First I will begin reading on Page 7949;

"By Mr. Keffer:

"Q. Mr. Hammer, we were discussing yesterday the matter of quadrants and the way in which you have utilized them. I will ask this in that connection, if your approach to this problem in the application of the pressure decline method has been the orthodox approach to a problem of this character by utilization of that method."

Mr. Keffer: That's right. I asked that question. That isn't the one you asked.

Mr. March: Mr. Keffer, I've got the floor here and you will have the witness on recross.

Mr. Keffer: You state it the way I asked him the question and there will be no objection from me.

Mr. March: "A. Well, it has been used by others in similar proceedings.

"Q. You mean the dividing of a field such as this into quadrants?

"A. Into areas. They didn't call them quadrants, but it has been done."

Q. Now let's take the next question that Mr. Keffer asked:

"Q. Where has it been done?

"A. That has been done in the case of the recent estimate by the Phillips Petroleum engineers and geologists."

Then Mr. Keffer asked the question:

"Q. They didn't divide them into quadrants like you did, did they?

"A. Areas.
"Q. Didn't they follow contour lines pretty well?
"A. In certain instances but not in all instances.
"Q. And you haven't followed them at all?
"A. No."

Then the cross examination in regard to that continues on.

The Trial Examiner: Now what is your question?

Mr. March: I am just getting to it.

Q. You recall that, do you not, Mr. Hammer?
A. Yes, I recall it.
Q. Did the Phillips Petroleum Company use a similar method to yours in estimating the reserves of the Panhandle field?
A. They did, very similar.
Q. And just approximately how did their estimate of reserves compare with yours?

Mr. Keffer: Just a moment, just a moment. If they want to prove the Phillips Petroleum Company's estimate, let them have the man that made the estimate come in here and withstand cross examination. You can't prove a reserve estimate by any such indirect method as that.

Mr. March: We aren't attempting to put on an estimate of reserves of Phillips Petroleum Company. We are attempting to show that the method employed by Mr. Hammer was a well-established method, that it had been used previously, been tried, and that the results were not unlike his. I haven't asked him for the specific estimate of the reserves.

The Trial Examiner: You are objecting to the question, Mr. Keffer:

Mr. Keffer: Yes, I am.

The Trial Examiner: The objection will be sustained.

By Mr. March:

Q. Do you recall as to whether or not Phillips Petroleum Company in its estimate of reserves attempted to employ the porosity thickness method?

A. They did not.

Mr. Keffer: Now, if Your Honor please, even on that, that is a pretty broad question. Mr. Hammer may know and he may not, I don't know, but certainly whether or not they attempted to use the porosity thickness method, the man that did the estimating is the one to answer that. It is wholly hearsay.

Mr. March: This quesion is entirely different—

The Trial Examiner: Mr. March, the witness has answered the question. It can do no harm in the record.

Mr. Keffer: As it stands now, I don't see as it would, really. It is rank hearsay and hearsay testimony I believe proves nothing. I think the courts have held that, and with that thought in mind, it makes no difference, if the Examiner agrees with me.

By Mr. March:

Q. Mr. Hammer, do you know whether or not the Phillips Petroleum Company have substantial acreage in the Panhandle field or not, of your own knowledge?

Mr. Keffer: If the Examiner please, just there, again, this is going far into the night, probably, on this line of—

Mr. March: I have only a few questions here I am going to ask on this.

Mr. Keffer: Whether the Phillips Petroleum Company has much acreage or little acreage could have no possible effect on an estimate of reserves made by them or anyone else. That doesn't affect the reserves to the slightest extent and I, therefore, object to that question as wholly irrelevant, incompetent and immaterial.

The Trial Examiner: Well, if the witness knows—the witness has gone over the field—he may answer.

The Witness: Well, I did have occasion, Mr. Examiner, to check roughly the acreage that the Phillips Petroleum Company have in the Texas Panhandle field in connection with the application of the Independent Natural Gas Company that was made to the Federal Power Commission. At that time I was requested to check the acreage that they

held in the Texas Panhandle field. I don't recall offhand the figure at which I arrived, but I do know that they have a very large and substantial acreage in the Texas Panhandle field.

By Mr. March:

Q. Mr. Hammer, I am going to read you a quotation and I am going to ask you if you agree with it. If you don't agree with it you can say you don't agree with it. This quotation is one I will read to you. It is contained in the physical transcript of the record in the matter of Independent Natural Gas Company, Docket No. G-178, Federal Power Commission, Page 305 and 306, and I just want to know whether or not you agree with that portion of the testimony of Mr. C. E. Turner. Do you know who Mr. C. E. Turner is?

A. I know he is an engineer with the Phillips Petroleum Company.

Mr. Spencer: Now, Mr. March, before we start reading into the record—

Mr. March: We can always strike. If the Examiner rules, it will be stricken. I have a right to ask the witness whether he agrees with a certain statement or not.

Mr. Spencer: We are getting right down to the thing the Examiner ruled on.

Mr. March: It is not getting to the estimate of reserves at all. I am just reading from this authority here and asking him if he agrees with the authority. That's all I'm doing.

Mr. Spencer: Well, I think very early in these proceedings we had a discussion about reports made by experts and as I recall you objected, that you did not have any opportunity to cross examine the expert and the Examiner agreed with you.

Mr. March: That's right.

Mr. Spencer: Now, we do not want you to read anything into the record from any expert on this subject that we cannot cross examine.

Mr. March: There has been read into the record here and prepared in exhibit form even quotations from tax reports in regard to technical matters. This porosity thickness method is a technical matter, and anybody can read from the sworn statement of an expert and ask a witness on the stand whether he agrees with him or not. I am not putting in evidence here the testimony of a witness here which is not permitted to be cross examined. I am merely asking him whether he agrees with this expert or not.

The Trial Examiner: Let's get this straight, Mr. March: You are trying to put into the record in a backhanded manner testimony of some other witness before the Federal Power Commission. Now, the Examiner is not going to permit it and there is no use of taking up time on matters of that nature.

Mr. March: The Examiner can say so and that is all there is to it. However, it was not with the intention of putting in evidence in a backhanded manner. Commission's counsel accedes to that because it was merely an attempt to here quote from an expert just like I would quote from a text book. I can quote from text books here by any individual as to the definition of permeability and porosity, can I not? I want to know because I may want to take a quotation from a text book and ask him if he agrees with that definition.

Mr. Spencer: A recognized text book is a whole lot different than reading out of another proceeding before the Federal Power Commission. The testimony is for one purpose and the text book is for another.

By Mr. March:

Q. Mr. Hammer, on yesterday we went over in the record—Mr. Keffer went over in the record a long series of reasons you have—five reasons you have on Page 15 of your written statement as to why this reserve figure that you have up here is a minimum estimate of reserves. Will you get your written statement out so we can go over those points at this time? Have you got those out, Mr. Hammer?

A. I have.

Q. Now, I believe the first reason here that you gave as

the reason for this minimum estimate of reserves is (1) "Stabilization of pressures are seldom if ever reached during the 'closed-in' period prior to determination."

A. That is the first one.

Q. Will you explain it just exactly for the Examiner—simply show everybody here just exactly what you meant by that.

A. Well, I meant, as I stated yesterday, that closed-in pressures in a field are seldom if ever obtained up to the maximum that might be delivered. I mean the maximum pressure that might be obtained at the well head when all other wells are producing gas or in the immediate vicinity of the wells where the pressure is being taken, and the location of the wells. There are all sorts of variabilities in the permeability fa[illegible]r.

Pressures might build up rapidly in one area and take a longer time to build up in another area because of the permeability factor. Under conditions of that type the wells never are on the average allowed to remain closed sufficiently long to get a real stabilized pressure. Now, if you take the question as it was discussed yesterday as to the fact that the isobars which we used based on closed-in well head pressures and as to whether the curves that we projected were based on minimum pressures, that is true, but that is just the point I want to make and I thought I had made it yesterday.

If your isobars are low and if a pressure decline curve is low, the facts are that if you had the better pressures, then they would be—your curves and your isobars would be drawn on that higher pressure. Now, you project a curve—

Q. You so projected a curve for illustrative purposes here?

A. I have projected a curve for illustrative purposes, yes.

Q. Let's describe your curve that you have drawn.

Mr. Keffer: Let him finish his statement.

Mr. March: I object to the interruption by opposing counsel. I want to ask the witness to illustrate this curve here. I have asked him whether he drew the curve or not.

Mr. Keffer: You broke in in the middle of the witness' answer of the other question.

The Trial Examiner: Had you completed your statement, Mr. Hammer?

The Witness: Well, will you go back and see when I quit?

(The record referred to was read by the reporter as set forth above.)

The Witness: I will make just one more short sentence to finish that statement: You project a curve on the higher pressures and its intersection will hit farther out, always, on your volume ordinant.

By Mr. March:

Q. Now, as I understand this, Mr. Hammer, in regard to your first reason here you have, we'll say right here in the middle of this piece of paper a well, and you have formations all out around that well. You tell me whether I am right or not—formations all out around the well. You have gas in that formation.

A. That's right.

Q. As I understand it, when you gauge these pressures you don't shut the well in and let the field equalize. You don't have an equilibrium pressure?

A. Not a true equilibrium pressure.

Q. That's right. As I understand it here—

Mr. Keffer: If Your Honor please, I don't know what he is leading to. I don't think it makes a lot of difference, but I want to call the Examiner's attention and Mr. March's attention to the fact that he is making a statement and putting the answer in the witness' mouth. So far it doesn't hurt.

The Trial Examiner: Go ahead, Mr. March.

By Mr. March:

Q. As I understand it, in view of the fact as you have stated here that you don't shut in the wells and let the pressures all equalize, that the pressures in these surrounding formations are always higher than the pressures are at the bottom of the hole.

A. In general I think that is true.

Q. And so even if you take your measurements by dead weight measurements, which is actually absolutely accurate, assuming that, the measurement of the gas pressures at the bottom of the hole here would be lower than in this surrounding—in these surrounding formations, is that right?

A. Yes, if your pressures had not reached stabilization, that would be true.

Q. And they haven't reached stabilization in the Panhandle field to your knowledge, have they?

A. I am speaking now about where you take pressures locally in a given area of two or three miles around a well. In discussing the thing with engineers of the Texas Railroad Commission I got the impression that they did not close wells down over great areas in order to take their closed-in pressures, and if they didn't close in considerable areas all at one time, their closed-in pressures as taken would be a minimum.

Q. And the pressures here at the bottom of the hole would be naturally, since they weren't allowed to equalize and come up in the hole, would be lower than in the surrounding formations?

A. That would be true.

Q. In other words, as I understand it, in every case that is the reason you stated that in practically every case you would get a minimum pressure?

A. That is I think true.

Q. Now let's go to this diagram which you say you have drawn here which illustrates that very well, as to the results as I understand it, and you may explain that as to what type of diagram you have here and what it illustrates.

A. Well, it is simply illustrative. I have just projected two lines, one representing a curve drawn on the pressures, say, that we took, and one drawn at a pressure somewhat higher, the lower one representing the pressures as we realized them and the upper one representing the pressures that would approach more closely to stabilization. In other words, the higher pressures.

Now, if you project a curve, using the somewhat lower pressures, it will hit at a less distance from the zero point

on the volume ordinant than it will if you utilize the higher pressures that would exist. In other words, your point using the higher pressures would hit the volume ordinant at a greater distance from zero, giving you in volume a larger reserve.

Q. In other words, you have drawn a diagram there which, as I understand it, and see if I understand you correctly, on which you have your pressures and production applied against your pressures.

A. Diagrammatically, yes.

Q. Diagrammatically, and roughly for illustrative purposes?

A. That's right.

Q. And then you have that diagram there and you extend a line diagonally down across this paper making a rectangle. The line which you extend down is illustrative of the pressures actually taken at the lower levels?

A. That is right.

Q. In other words, the pressure taken without shutting in the whole field or the whole surrounding territory and allowing them to equalize which would naturally, as you state, be a lower pressure?

A. A lower pressure, that's right.

Q. Now, if the field had been shut in or if the pressures had been allowed to equalize, as I understand it, you state that the pressure at the bottom of the hole in the well would have been higher, therefore, you would draw another line to illustrate these entire pressures?

A. The pressures at the well head or the bottom of the hole, each one would have been higher.

Q. That's right.

A. The point is that with those higher pressures plotted against whatever accumulated production you would have, you would get a greater distance projected out on the volume ordinant of your coordinate paper, thus on pressures alone giving you a greater reserve.

Q. And so that is the reason why, as you have stated here in your point 1 that this is a minimum estimate of reserves?

A. That would be one of the reasons.

The Trial Examiner: We will stand in recess for five minutes.

(At this point a short recess was taken, after which proceedings were resumed as follows:)

The Trial Examiner: The hearing will be in order.

By Mr. March:

Q. Mr. Hammer, in my question a few minutes ago I spoke of the bottom hole pressure. What I meant I think was—tell me whether I am right or not—well head gauge pressure.

A. That is what I used throughout, well head gauge pressure.

Q. That is the correct terminology?

A. That is right.

Q. I was mistaken on the bottom hole. Now, Mr. Hammer, your second reason here as to why this is a minimum estimate of reserves, Page 15 of your written statement, as I read it is as follows:

"During the period used for determination of reserves, only metered gas was employed. No estimate of wasted gas was made."

Now, will you explain what you mean by that in your own words.

A. Well, just exactly what the thing itself states, that we did not take into consideration anything except metered gas. Now, anyone who has studied the Panhandle field knows that there was an enormous wastage of gas beginning probably in its worst state—oh, between the years of 1926 and 1929, and that it became so bad that the Texas Railroad Commission felt justified in doing something about it and in 1935 they took steps to try to prevent that sort of wastage.

Now, as I understand it, while the orders promulgated by the Texas Railroad Commission were effective as of August 1, 1935, that actually the wastage continued throughout, but maybe with somewhat less degree, throughout the remainder of 1935 and well into 1936 and it took some time after that before the wastage was eliminated. In fact, even as late as 1939 there was considerable gas reported as gas that was not metered, by the Texas Railroad Commission.

The point I am trying to make is that even after, or during the period from 1935 to 1939, there was a considerable amount of gas which no metered record existed, but the only thing we took was the metered record, and any amount of gas coming out of the ground unmetered, if we had utilized that gas in our estimate of reserves we would have undoubtedly had a larger estimate that we have submitted.

Q. Have you prepared a diagram similar to the diagram that you had a few moments ago which illustrates generally and roughly just exactly why this is an estimate in that respect because of that reason?

A. Yes, I have.

Q. Will you describe it and discuss it here?

A. Well, I have drawn an illustrative curve showing that although—if it had been possible for us to get the more accurate pressure and would have projected that through with some more accurate pressures, yet if we did not have the total gas withdrawn, that the accumulated points on the volume ordinant in the projection of a curve at the same pressures would have extended further out on the ordinant from zero and when projected through would have given you a very much larger estimate of reserves.

Q. Now, let's see if I understand this: Here you have drawn a rectangle, as I understand it—

A. No, it is a triangle.

Q. I mean a triangle, with pressures on the left-hand side and your volume at the base of the triangle.

A. One is the pressure ordinant and the other is the volume ordinant.

Q. This line runs across intersecting the two ordinants. The first line here represents roughly the production figure that you did use, just for illustrative purposes.

A. That represents—that line represents an accumulated production against a pressure decline.

Q. Was that the recorded production?

A. The lower one would represent the recorded production.

Q. And the higher one represent the—

A. Would represent roughly the condition that would exist if you had taken into consideration all unmetered gas.

Q. In other words, as I understand you to say there

that there has been considerable gas produced since 1935 which has gone unmetered, there is no record of it.

A. I think that is a true statement.

Q. Some of it has been blown into the air and *other* disposed of without any reliable data as to the accurate amount.

A. That's right.

Q. And it is simply your contention here that this is a minimum estimate of reserves because if you had had those figures, the complete figures as to all the gas which had been produced, your estimate of reserves would have been higher?

A. That's right.

Q. Now, is it your position, though, that since 1935 there has been such reliable data as to production that you are enabled, taking the five-year period, to make an accurate estimate of reserves by the pressure decline method?

A. As I see it, we made an estimate based on metered gas only which in my opinion gives us a minimum estimate.

Q. However, Mr. Hammer, what if you had—oh, yes, I believe you testified on cross examination that you did not take the period beginning 1928 and extended to 1939 because of the unreliable information back of 1935, is that right?

A. That is right.

Q. That is still your opinion?

A. That is still my opinion.

Q. And you have made some effort to ascertain whether or not you can get reliable data prior to 1935?

A. I think I have made as much of an effort as anybody could.

Q. And would you yourself as a geologist and engineer want to rely upon an estimate of reserves by the pressure decline method taking the entire production of the wells—

A. From the beginning?

Q. Yes, with the data that is available.

A. No, I would not. That is the reason I didn't use it.

Q. Well, then, Mr. Hammer, I want to dispose of the other three. You have three other reasons here, three more, as to why you consider this a minimum estimate of reserves.

Now, what have you got to say about those three reasons? There has been some confusion about those three reasons on cross examination—three, four and five, Page 15.

A. Well, those three are not the important three. Really the two reasons obtaining the minimum estimate are those covered under Items 1 and 2. I put them first because I felt they were the important ones.

Q. So far as you are concerned, the last three reasons there can be disregarded?

A. That's right.

Q. In other words, then, as I understand here as your testimony, you consider that you have given sufficient reasons in 1 and 2 to sell this proposition?

A. I think so, with the exception, Mr. March, I think that the information contained in one or two instances, one in particular, and I think in another, are the annual reports of the Texas Railroad Commission which indicate rather definitely something about the wastage of gas during the—particularly during the latter part of 1935 and the first part of 1936. For instance, in the 1937 annual report of the Railroad Commission of Texas and on the sheet following Page 14 of that report under the general heading of disposition there is a series of graphs—or, rather, a graph that shows that the Commission's orders for the utilization of available casing head gas did not occur until April or thereabouts in 1936 and that during the latter part of 1935 and up to about April 1936 there was a lot of gas blown into the air. This is simply in the form of a graph. It shows the withdrawals to be estimated in millions of cubic feet representing one ordinant of the graph and the years and months representing the other ordinant of the graph.

Now, it does show the reason is due to carbon black beginning in 1935 and going on through, but it also shows that during the latter part of 1935, particularly, that there was a considerable amount of gas which was not utilized even for carbon black. I can't state definitely how much of the gas that came from the ground actually was blown into the air during that period of time, but the interesting thing is that the Commission's orders for the utilization of available casing head gas apparently weren't issued until about April of 1936; so during the time between August 1935 and April 1936 there was unquestionably a lot of gas that was not metered and of which we had no record.

Mr. Keffer: May I make a statement with respect to the graph?

Mr. March: Go right ahead, Mr. Keffer.

Mr. Keffer: As a matter of fact, Mr. Hammer—

Mr. March: Are you going to cross examine the witness?

Mr. Keffer: I am just going to call his attention to what the map shows.

Mr. March: Well, you can do that on recross.

Mr. Keffer: All right.

The Trial Examiner: Did you state the year of that report, Mr. Hammer?

The Witness: Yes, August 1937.

Mr. Lange: You mean the date of the Railroad Commission report itself—November 1938.

Mr. March: You can ask one question, Mr. Keffer. A series of questions is what I had reference to.

Mr. Keffer: As a matter of fact, doesn't the graph show that the gas blown into the air started down *precitously* from shortly before October, probably about the middle of September 1935?

The Witness: No, I think you are a month or two off—well, it would be up here some place in November.

Mr. Keffer: All right, November 1935, and hit the bottom in April 1936 and then started up a little.

The Witness: Yes, that's what the graph shows.

Mr. Keffer: And from November 1935 to April 1936 the volume of gas blown into the air decreased from more than 600 million in November of 1935, to probably no more than a hundred million in April 1936?

The Witness: That is true.

Mr. Keffer: All right, then, the statement that you just made that it didn't start until April 1936 is hardly a correct statement.

The Witness: I made no such statement. I said the

Commission's orders were to put into—were exercised about that time.

Mr. Keffer: What started it down back in April of 1936—

Mr. March: All right, I object to that. I was only consenting to a question here. If you want to argue with the witness you can argue with him when I am through.

Mr. Keffer: All right.

By Mr. March:

Q. I gather that all of those reasons are to be applied under your No. 2.

A. That's right.

Q. In other words, your position is that even since 1935 there has been a considerable wastage and unrecorded volumes of gas which you did not consider in your estimate of reserves?

A. That is absolutely true.

Q. Now, in regard to the statement you make on Page 15 of your written statement, they are merely observations as I gather it, are they not?

A. That is right.

Q. They are not an essential part of your estimate of reserves, are they?

A. No, they are not.

Q. All right, I next direct your attention to Exhibit 180, to the diagram on Page 4-B, entitled, "Illustration that Calculated Pressure Decline Conforms to the Pressure Decline Plotted Against Accumulated Production."

Have you turned to that yet?

A. Yes.

Q. Do you recall the discussion in regard to that, with Mr. Keffer, in regard to making a straight line—I mean a crooked line straight? You recall those discussions, do you not?

A. Yes, sir, very well.

Q. All right, Mr. Hammer, I will ask you with regard to that top line extending across the diagram there, from which side of the paper you started drawing that line?

A. Well, in this particular instance I plotted those points giving the slope of the curve on the calculated accumulated

withdrawals as against pressure declines, the calculated accumulated withdrawals being computed by the factor of 35.1 Mcf. per acre pound decline as applicable to the area covered by this curve.

Q. My question was, from which side of the paper you started drawing that top line extending across the diagram there.

A. It doesn't make any difference. I simply drew the curve through those points established by the method as I have indicated.

Q. Yes.

A. Then later on I plotted on there the actual accumulated production against the weighted pressure decline and the points thus plotted fell at their proper position on the curve.

Q. Those latter are represented by those little dots, is that right?

A. That is right.

Q. And the large circles represent your previous calculation?

A. That's right.

Q. So as a matter of practice, while it does not make any difference whether you start drawing the line—actually, you started, did you not, and you tell me whether I am right or wrong, from the right-hand side of the page and extended it over to the left-hand side of the page?

A. As I say, that makes no difference. The point is that I could have plotted those points on the production—the accumulated production—against the weighted pressure decline, either before or after the production projection of this curve and you would have had the same result.

Q. I notice all the large circles, they go right through the center.

A. That's true.

Q. Why is that?

A. Because the calculation of those points is an accurate mathematical calculation.

Q. Which is well established in the engineering fraternity?

A. That's right.

Q. Mr. Hammer, have you had a great deal of experience in calculating just such sorts of graphs such as this here?

A. I have made a great many graphs over a long number of years.

Q. In your experience have you had any graph that comes out any more nearly in a straight line than this graph comes out—I mean the points plotted there on that, speaking of the left-hand side, the little points up there?

A. No, that is the reason we utilized the method that we did use, and that was to eliminate the personal element in the construction of a curve and relied solely on the mathematical determination of the proper slope.

Q. In other words, on the left-hand side of the page the little dots, although they do not fall exactly through the center, the line doesn't—as I understand it—that is, as I observe the thing here, every one of them at least touches the line?

A. They fall in their proper position to the line, either above or below.

Q. Now, why would you say that they did fall, some just slightly off the center of the line?

A. For the reason of the variations in the actual accuracy factors entering into the problem from time to time.

Q. In other words, on the left-hand side of the page here as I see it you have an indicated slope here which in so far as these mathematical calculations are concerned, they are used in the engineering fraternity, it is an excellent slope from which to determine—to project an accurate line?

A. I say, that it is the best slope that it is possible to devise to a given set of points that do not fall on a straight line.

Q. Now, you recall yesterday that there was a graph drawn for you by opposing counsel on which he plotted his pressure on one side of the rectangle and on the bottom of the rectangle he plotted years. Now is that sort of a graph in any respect comparable to this sort of a graph?

A. No. As I stated yesterday, from any practical standpoint on the question of estimation of gas reserves, the plotting of pressure points against time alone is of no value.

Q. This chart doesn't do that, doesn't attempt to do that?

A. No, not at all.

Q. Now, is this diagram here on Page 4-B a part of your estimate of reserves?

A. No. It wasn't necessary at all to even construct that. The only reason for constructing that was to illus-

trate the method used to determine a proper slope of a curve, and if that were calculated out it would give the proper answer as determined mathematically. It is simply illustrative of the method used. It was not necessary.

Q. You merely prepared this as a matter of accommodation?

A. That is right.

Q. To simplify the understanding of what you had done, and the same is true in regard to 4-C, is that right?

A. That is right.

Q. Now, Mr. Hammer, we have heard a great deal about drainage here. As I understand your position, and I think you have stated it several times in the record—if I am not right in my understanding I want you to correct it—that you did not consider separately and specially the problem of drainage in this exhibit. However, you had to, as I understand it, in drawing isobars, you automatically took into consideration dranage.

A. Well, the isobars is a misconception. There is a misconception about what isobars are. Isobars simply show lines of equal pressure. Now, when you step from one isobar line to another, either up or down, it simply shows the differential in pressure between those two isobar lines. If one will keep in mind the fact that you must make an estimate of reserves as of a certain time, then in utilizing the isobars in the determination of reserves as of a given time, it is not necessary to take into consideration, except as it may affect things locally, the question of any regional drainage.

Q. You recall that there was some discussion about this Lefors area, I believe it is, up here in Quadrant 6. I believe as I recall, and you correct me if I am incorrect, that you testified and you and Mr. Keffer agreed that there is a low pressure area there caused by excessive withdrawals, is that correct?

A. Yes, in the Lefors area there has been enormous withdrawals of gas and the pressures as of 1939 were quite low.

Q. Why, Mr. Hammer, if the gas moves freely from the high pressure to the low pressures, as Mr. Keffer assumes, why is it that this Lefors area in your opinion did not maintain its pressure? In other words, why didn't it drain to terrtory surrounding it and maintain its high pressures, and the high pressures be reduced around there?

A. That is simply—I think we can clarify that somewhat by stating that we take the area just along west and southwest of the town of Lefors. Now, it is a noticeable fact that although there have been enormous withdrawals of gas out of that area just west of the town of Lefors due to the large number of oil wells that exist there, it is a noticeable fact that the pressure gradient up against that low pressure area has been a steep gradient over a period of years, for several years, and that there still remains relatively high pressure areas up close to it.

In other words, it did not all rush into that area just west of Lefors because of a great pressure differential that existed there. It is a case, I think where the history of the last five years at least is that that pressure gradient has maintained approximately the same position throughout the five years, although there has been a decline for the region.

Q. So if there had been a free movement of gas in this one case here; for example—just take that exception—from the high pressure to the low pressure, then as the gas is withdrawn from this low pressure zone here causing the low pressure zone, the high pressure should have been maintained there because the gas would be coming in from all directions there?

A. The point there is that if there had been rapid gas migration the areas of low pressure would not have reached the low pressure that now exists because gas would have moved in and replaced it.

Q. All right, now, Mr. Hammer, would you say that this area down here in the east end of the field could drain gas from the Canadian River acreage?

A. Most certainly not.

Q. Would you say that it could drain gas from the west end of the field at all for any practical purposes?

A. Not at any time when any of ourselves would be living, no, or maybe a good many generations.

Q. Your position is—is it your position that for all practical purposes in estimating reserves that so far as Canadian River acreage is concerned that you can forget all about the eastern part of the field?

A. Oh, yes. It hasn't any bearing on it whatsoever. I agree with the position of the Texas Railroad Commission that for all practical purposes there is no direct actual con-

nection between the two, between the area from Lefors east and Lefors west.

Q. Is that your principal reason for stating that in estimating the reserves for the Canadian River acreage which is in the west part of the field that it is not necessary to make an estimate of the reserves of the entire field?

A. That is true.

Q. Now to bring this drainage problem home, Mr. Keffer tried to, when he said the Borger area here caused this—indicated on your map, Exhibit 179—the pressures in the Borger area were substantially lower than the pressures in the Canadian River acreage, that that was according to your map an indicated drainage, and as I recall you stopped him at one place and went over to the map here and pointed out that as a matter of fact—actual fact, the pressures in some of the Canadian River acreage was being maintained in practice in spite of the pressure differential.

A. I pointed out certain factual things there.

Q. You don't have to go over them. Is that generally true?

A. That is true.

Q. And in regard to your general knowledge, would you say, or could you state as to whether or not that if pressures were being maintained—high pressures were being maintained reasonably well in this Canadian River acreage in spite of the pressure differential between some of it and the Borger area?

A. Read that question.

(The question referred to was read by the reporter as set forth above.)

Mr. Spencer: Before you answer, Mr. Hammer, we have no objection to the question, but can you make it a little more definite as to what you mean by "reasonably well," so there will be no misunderstanding later, Mr. March?

Mr. March: Well, I'll let the witness answer the question and then I will ask a question in that regard. He can answer the question, if the question is clear to him.

The Witness: A question of that kind is a question of several factors which must be taken into consideration to arrive at a proper answer.

By Mr. March:

Q. You don't feel, then, that you want to give it?

A. At the present moment I would rather reserve my answer on that question.

Q. Well, you will not be expected to answer the question because as I understand you have not made a detailed study of the drainage problem.

A. No, my study has been a reserve study.

Q. And you would rather just let your testimony stand specifically in regard to certain parts of this acreage which you have already given?

A. For the present, that is right.

Q. Now, Mr. Hammer, one other question on this and that's all I have.

Now, if in spite of the pressure differential down here in the Lefors area the pressures did not build up enough there to maintain the pressures and they were not substantial reductions in pressures all around there as a result of that low pressure, is it reasonable to assume—is it less reasonable to assume that there would be any different situation in regard to the Borger area draining the Canadian River acreage?

A. That is a comparison again of so many factors entering into an answer it would have to be a relative answer. I would say, as I have tried to say before, and on which point I have a very definite impression, that if it had not been for the development of gas back from these oil fileds and if the gas withdrawals from the oil fields alone had been taken—had been the only cause of pressure decline, a great part of the entire Texas Panhandle field in my opinion would still have its original pressure.

Q. That's all of that I want to ask you, but I want to ask you one question in regard to sour gas.

There has been some question indirectly raised about the commercial utilization of sour gas for pipe line purposes. Do you think that sour gas can be utilized commercially for pipe line purposes?

A. Oh, yes, it is being done.

Q. By what process?

A. Well, there are several processes.

Q. I mean, what general process—desulphurizing?

A. Desulphurizing.

Q. Where is that being done?

A. It is being done by the El Paso Natural Gas Company.

Q. In your estimate of the reserves, therefore, you have included both sweet and sour gas?

A. That's right.

Q. From your study of the Panhandle field, would you state that if conditions continue as they are, assuming they do, that less and less sour gas will be utilized for carbon black purposes and more for pipe line purposes?

Mr. Keffer: Now, if the Examiner please, I would like to now what—if the witness is qualified to express an opinion as to what is going to be the future of sour gas service.

Mr. March: No, I said "assuming." I didn't ask him to give any—I said "assuming," like you did here yesterday time and time again, assuming that conditions remain as they are today, assuming that the trend continues as it is today, as to whether or not it is reasonable—whether or not in his opinion it would be a reasonable assumption to assume that a larger volume of sour gas would be utilized for pipe line purposes and that less volume would be utilized for carbon black purposes.

As a matter of fact, your company is going to put in a desulphurizing plant.

Mr. Keffer: You are getting away from your assumption, Mr. March. You first start out with an assumption and then you ask the witness to make still another assumption.

Mr. March: Read the question.

Mr. Keffer: I think it follows that you cannot base an assumption on an assumption.

Mr. March: Let's read the question and see how many assumptions I have got in the question.

(The record referred to was read by the reporter, as set forth above.)

Mr. Spencer: Now, Mr. Examiner, he has assumed the

conditions will continue, but those conditions I assume involve the market for carbon black. If so, I would like to know what the witness knows about the carbon black industry.

Mr. March: You can have him on redirect, Mr. Spencer. You can ask anything he knows about the carbon black business and the weight can be given the testimony as the Examiner sees fit. He has been asked lots of questions about carbon black, where it is located, and he has been examined for days about some of these very things. They can ask the witness whether he knows anything about it.

As a matter of fact, he was even required to state the process for the manufacture of carbon black, going through the various steps.

Mr. Spencer: I object to the question until Mr. March lays a proper foundation as to the witness' qualifications to answer.

The Trial Examiner: Well, I question whether or not a proper foundation for the question has been laid. However, the Examiner is perfectly able to weigh the evidence and Mr. Hammer, if he has an opinion, he may state it.

The Witness: Well, actually, I thought I made that clear previously. I will admit that I would have liked to have had time to make a study of the carbon black industry but I did not have time to, so I don't propose to set myself up as an authority on the carbon black industry in the Texas Panhandle. That's my position exactly.

By Mr. March:

Q. And you would rather not answer that question for the reasons that you have given to Mr. Keffer from time to time as the reason for not answering questions about these particular matters?

A. That is right.

Q. In your study, as I understand it, you did not give any consideration so far as this exhibit is concerned, as to where the gas went to?

A. That's right. My problem was to take the gas as near as I could as it came from the wells regardless of the

disposition of the gas afterwards. I made no study of disposition of gas.

Q. Now, there has been some questions asked you about permeability and porosity here. In your opinion can you express one of those in terms of the other?

A. Not at all.

Q. In your opinion that would be ridiculous, is that right?

A. Yes. There is a relationship, of course, but you can't express one in terms of the other.

Q. That is a fundamental law of physics, is it not?

A. That's right.

Mr. March: Now, I am just about through, Mr. Examiner, but I want to get a final ruling here as to whether or not in spite of the fact that the witness was interrogated regarding the Phillips Petroleum Company estimate of reserves, the method employed; whether or not the ruling is that I can't ask any questions in regard to that.

The Trial Examiner: Well, Mr. March, there is no connection between the Phillips Petroleum Company and the respondents in this proceeding. It is my opinion that it is highly improper to take a proceeding—

Mr. March: I don't mean that. I am forgetting about that. I am talking about something else. In other words, the witness was asked questions as to the method employed as to whether or not they were the same method and whether or not the field was divided up into quadrants and, in fact, as I read a few minutes ago—I am not going to read any testimony. I accept the Examiner's ruling on that, but I want to find out the extent of the Examiner's ruling. I want to know if I am going to be precluded from going into these things I have mentioned on redirect examination.

The Trial Examiner: That is not the question. You haven't been precluded from going into the proper redirect, Mr. March. That is not the situation at all, but the question here is the propriety of the use of testimony.

Mr. March: I accept the Examiner's ruling on that. We have forgotten about that now. I want to know the extent of the Examiner's ruling. I didn't want to ask the witness until I found out because I thought it wise not to

impose on the Examiner in that regard if the ruling is that we are not to ask any questions in regard to the methods of the Phillips Petroleum Company estimating reserves in spite of the fact that those questions were brought up themselves by opposing counsel.

The Trial Examiner: Mr. March, it had been brought out that the Phillips Petroleum Company utilized the pressure decline method for estimating reserves in the field. At least, Mr. Hammer has testified to that. Now, if you have any redirect on that sort of thing, it is perfectly proper and the Examiner will go along with you on it.

* * * * *

The witness further testified on redirect examination, Vol. 61, pp. 8531-8540, as follows:

Q. Mr. Hammer, I believe you testified the other day that the Phillips Petroleum Company made an estimate of the reserves employing the pressure decline method very similarly to the way you employed it in your estimate.

A. That's right.

* * * * * *

Q. Mr. Hammer, do you know of your own knowledge of anyone since 1935 who has attempted—who has made an estimate of reserves of the Panhandle field on the porosity thickness method other than Mr. Peterson and Mr. Thompson who are in this hearing room right now?

A. To my knowledge I don't.

Q. There is one other question, I believe, Mr. Hammer that you were requested to give the Canadian River—give the Canadian River a statement of original reserves under the Canadian River's own acreage. I believe you did comply with that request, did you not?

A. Yes, I gave them a sheet in tabulated form.

Q. Have you got that here?

A. It is on a yellow sheet, a long yellow sheet.

Mr. Spencer: I don't seem to have it.

Mr. March: He can get along without it.

Q. Mr. Hammer, in spite of the fact that the figures which you say that you gave to the Canadian River in the hearing room, will you state for the record the original

reserves under the Canadian River acreage as you found them, such explanation in regard thereto as you see fit?

A. The calculated original reserves in place beneath the Canadian River Gas Company's acreage as of August 1st, 1939, is 4,058,700,000 Mcf.

Q. Do you desire to make any explanation in regard thereto, Mr. Hammer?

A. Yes, I would like to make a comparison.

Q. You may proceed.

A. The calculated remaining reserves beneath the lands controlled by the Canadian River Gas Company as of August 1st, 1939 was 3,645,213,000 Mcf. at 25 pounds abandonment pressure, and on a pressure base of 14.65 pounds per square inch absolute.

The calculated original reserves in place beneath the same lands at the same pressure base as of the same date of August 1st, 1939, 4,058,700,000 Mcf.

Now, there had been withdrawn metered gas from the Canadian River Gas Company and predecessor company wells on the Canadian River leases from the beginning of operations up to August 1st, 1939, a total of 379,085,559 Mcf. of gas, calculated to a pressure base of 14.65 pounds absolute per square inch.

The remaining reserves beneath the Canadian River Gas Company lands as of August 1st, 1939 are calculated by the summation of reserves of that company's lands in each quadrant in which such lands exist and is 3,645,213,000 Mcf.

Mr. Keffer: What was that again? I'm not sure that I understood you, Mr. Hammer.

The Witness: 3,645,213,000 Mcf.

Mr. Keffer: Oh, yes. That's the figure you gave a while ago.

The Witness: Yes. If there be added to this sum the total gas withdrawn up to August 1st, 1939, or 379,085,559 Mcf., there results an original estimated gas in place of 4,024,298,000 Mcf. To recapitulate the ultimate original reserves in place by calculation, that is, by the summation of the calculations of their lands in various quadrants, 4,058,706,000.

Then the ultimate original gas in place by adding the past withdrawals to future reserves, 4,024,298,000 Mcf., a difference of the ultimate reserve calculation of 34 billion cubic feet—the percentage of difference in the two methods of arriving at the original reserves in place is 85/100ths of one per cent.

By Mr. March:

Q. In your opinion, does that prove the accuracy of your method?

A. I think without any question it proves the accuracy of it. I submit that the method I have used is, therefore, accurate, fairly determined and that the principles used in the determination of the gas reserves are as accurate as it is possible to be done by the available supporting data. Had it been possible to get the past withdrawal from each total quadrant, or for the entire field, as in the case of the Canadian River withdrawals, it is my opinion that equally close results would have been attained. Now, that, I believe, sums up the accuracy of my calculation as far as reserves of Canadian River Gas Company are concerned.

Q. And, likewise, furnishes the information requested by the Canadian River Gas Company?

A. Well, I assume that that is what they want it for. I gave them the information, but this is my summation of what the data shows.

Now, with not so much certainty, but, nevertheless, with considerable accuracy, the same statement can be made as regard the reserves of the field as a whole.

Q. Is that all, Mr. Hammer?

A. No, I'm not through. As a matter of a similar check on the field as a whole, I wish to submit the following: The estimated future reserves by the summation of all quadrant reserves for the entire field, 22,599,000,000 Mcf.

Mr. Keffer: That's remaining?

The Witness: That's remaining, that's right. The estimated total withdrawals — no, the estimated total withdrawals for the entire field up to August 1st, 1935, amounts to a figure of 4,833,608,743 Mcf. The total withdrawals from the field from August 1st, 1935 to August 1st, 1939, amounts to 2,430,370,036 Mcf.

Now, if we will add the future reserves plus the estimated field withdrawals to August 1st, 1939, plus the withdrawals from August 1st, 1935 to August 1st, 1939, the sum of these three items amounts to 29,862,978,779 Mcf.

Now, the total estimated reserves by the summation of all quadrants, including Wheeler County 1, is 29,979,000,000 Mcf., a percentage difference between the two methods of computation of 38/100ths of one per cent.

Now, there is one point here that I want to clear up. The total field withdrawals—I beg your pardon. The estimated total withdrawals for the entire field up to August 1st, 1935, were—or, rather is an estimate that I secured from the Phillips Petroleum Company late in 1940 at the time I was sent to Bartlesville for the purpose of investigating certain records in connection with the application of the Independent Natural Gas Company. That figure was taken from their records with a photo record machine and the data I give here were taken from an enlargement of the photo record taken from the Phillips Petroleum Company.

The Trial Examiner: Are you sure you gave the right date there, Mr. Hammer? Did you mean 1939 or 1935?

The Witness: Total withdrawals, 1935, from the beginning up to 1935.

The Trial Examiner: You said 1939 and I thought that—

The Witness: That's right. Now, it is my opinion that having checked ultimate reserves in two cases, one by the summation of the ultimates for individual quadrants and the other by adding past withdrawals to future reserves, eliminates the possibility of any great error in my estimate.

Mr. March: That's all.

* * * * *

The witness explained that in order to get a calculated reserve figure he takes the drop in pressure between any two given points and divides this into the production for the same period, which gives him the volume of production represented by each pound lost in pressure, and then multiplies this by 430, the original virgin pressure in the field. The acre pound factor is simply a factor for weight-

ing the pressures and pounds, but it is also necessary to multiply by 430 after the value of each pound of pressure has been determined in order to get the original reserves.

Witness stated that he procured the Phillips figures in 1940, and also he had not used the Phillips figures in any manner in making his estimates. He did not know how he would have checked his work if he had used them. He stated that if he had used the Phillips figures he would have gotten about the same answer, but in that event his calculations would have had to check with the Phillips figures. In other words, if the Phillips figures had been utilized to determine the production per pound lost in pressure and then multiplied back by 430, the original field pressure, the matters would necessarily have checked because they were based upon the same thing whether the calculations were right or wrong.

The witness then stated that the assumption of accurate production figures in the Texas Panhandle Field from the beginning to August 1, 1935, was a theoretical thing because data was not available during that period, but assuming that the figures were available and had been utilized in making his estimate, his calculation figure as to past production would have to check with the actual figures of past production and neither could be a check upon the other because they are the same in both cases.

Witness further testified on recross examination (Vol. 61, pp. 8562-8576) as follows:

Q. That's the whole point. All right, now, when you get down to the point where you have one pound, weighted the way you have weighted it, one pound represents so much production; then if you had 430 pounds to start with, the original reserve would have to be 430 times that. It just couldn't be anything else but that, could it?

A. You have got to have in there the acreage, though.

Q. How do you mean, "the acreage"? The only thing you used the acreage for was in your weighting process. Now, we have the weight. You have used your acreage for that. Now we are beyond that.

The Trial Examiner: Mr. Hammer, for example, if you wanted to go back and ascertain the original reserves, what would be the last step in your method of computation?

The Witness: Well, we would take the difference in pressure between any two given periods of time and on the determination of the production per acre pound for the area considered we would utilize the difference in pressure, weighted against the acreage involved and from that determine the ultimate reserves in place.

By Mr. Keffer:

Q. All right, just take a very simple example and illustrate it, will you please, Mr. Hammer? I think we can all save time and all understand it better.

A. Well, the whole thing is that you have to have the difference in pressures, and you have to have the amount of acreage. Now, if you will multiply your acreage by the difference in your pressures and then multiply that by your production per acre pound decline, you will get your figure.

Q. Will you take just one of the Canadian River quadrants—any one you want to select, and show us just how that works on there, one that will work out the easiest?

A. There is an illustration right there all worked out in my exhibit.

Q. Not to get back to original reserves, Mr. Hammer. I am quite certain of that.

Mr. Spencer: Mr. Hammer, while you have been testifying here I have gone through these papers that Mr. Keffer has and I believe I have located the schedule that you handed to us, if it will help you any in this.

The Witness: That's it.

By Mr. Keffer:

Q. All right, now, let's take Hartley County, unless you would rather take another one—Hartley County. If it would work on one, the same thing would work on all the others, I take it. Now, show me how you got that original reserve figure.

A. Well, it is very plain here just as I described it. You have your Canadian River acreage; then you have your acre pounds as of 430, original.

Q. As of 430?

A. Yes.

Q. How would you get that as of 430?

A. Well, when you get—that means the difference between the pressure as of 1939 and the original pressure.

Q. All right, but you had to multiply somewhere in there by 430 to get that, didn't you?

A. Oh, no, you didn't.

Q. How did you get it?

A. By plain unadulterated subtraction.

Q. All right, subtraction from what?

A. The difference between the weighted pressure for 1939—August—and the original field pressure of 430 pounds.

Q. All right, we have 14,358 acres—Canadian River acreage, County 1, is that right?—Hartley County 1.

A. That is right.

Q. All right, then you have acre pounds of 430 in your next column, which is 6,173,940. Now, I want to know how you got that figure.

A. I have explained that so many times I don't think it is necessary.

Q. If you will just be patient with me, I'll try to be patient with you.

A. Well, in this particular case here it was calculated from 430 to well head abandonment, I think.

Q. That's right.

A. And in that case it would be your acreage and your difference between 430 and 25.

Q. Well, now, you just did that and didn't get the right answer, did you, Mr. Hammer?

A. Well, in that Hartley there, there is apparently a slight error.

Q. Multiply the 430. I don't know what you get. Let's try it. You got close on 405, you might get it on 430 if you multiply that. I don't know that you would. I haven't tried it.

A. That's right, I see where the error is.

Q. Then you do admit you multiplied by 430?

A. That gives it down to zero well head.

Q. That's right, that's what we have been talking about.

A. That's right.

Q. Well, then, are we agreed that even on your method you have got to multiply in there somewhere by 430 to get your original content at zero well head pressure?

A. That's right, you multiply. The only confusion here was that I thought it was down to 25, you see.

Q. I see.

A. And actually that column is to zero.

Q. Yes.

A. And then that zero was calculated back to 25.

Q. All right. Then when you get your pressure drop as related to your production and divide your pressure drop into your production you multiply back by 430 to get original content, zero well head pressure?

A. That's what this amounts to. Of course here after you get your acre pound factor, then, of course, you have to multiply that by your production per acre pound.

Q. That's right.

A. And that gives you your answer.

Q. Your acre pound is just the method you have of weighting the pressures, isn't it?

A. Weighting the pressures and the pounds.

Q. And getting your pressure drop with respect to your pressures.

A. That's right.

Q. But you always have got to come back and multiply by your 430 when you get that down to one pound pressure drop whether you do it one way or the other way?

A. You have to utilize, of course—if you are figuring back to any place you have got to utilize that pressure.

Q. We're together on the thing we have been arguing about most of the morning, I guess.

A. If you state your problem a little more clearly—

Q. I stated it as clearly as I could. I'm sorry if you didn't understand it.

The Trial Examiner: We'll stand in recess for five minutes.

(At this point a short recess was taken, after which proceedings were resumed as follows:)

The Trial Examiner: The hearing will be in order.

There is no question pending, is there?

Mr. Keffer: No. I thought that Mr. Hammer was figuring something. That's the reason I hadn't asked a question.

Q Are you ready?

A. Yes, I guess so.

Q. Now, Mr. Hammer, we have got some of the underbrush out of the way. Let's go back to this original matter.

When you get your pressure decline over a period, whatever that period is, and if it is over several periods, and average them in, or weight them in as you have done and get your average weighted pressure decline and have your production for that period, you divide your pressure decline into your production and get the pressure decline, or get the production, rather, per pound decline, don't you, and multiply that by 430 and you have got your original reserves at zero pound well head?

A. I think that's what I have done here, that's right.

Q. That's right, all right. Now, the next question—then if you had gone back to the beginning of the field and taken Phillips' figures, for example, as the production prior to 1935 and taken your figures for production since 1935, thus having total production for the field as you have taken it and applied your method which you have done, I take it you would have come out with about the same figure that you have had?

A. I imagine I might have. The point there is, of course, I couldn't for the reason that the great part of all the calculations were completed before I ever got hold of the Phillips estimate of past withdrawals. I didn't get it until late in 1940 and the utilization of that was an afterthought, after I had secured the others—the principal calculations were all complete.

Q. Then, if you had done that, how would you have checked your work?

A. I don't know. I never used it.

Q. Well, I know, but if you had taken that figure and run it through together with your figure which you did, that is, the estimate for those prior years, plus your actual production figures as you have them for the later years, that is, from 1935 on to 1939; then on your theory, assuming that your method is right, you would have still come out with about 29 billion plus at 25 pounds abandonment, wouldn't you?

A. I think that is right.

Q. That's right.

A. The point is I didn't have them so I didn't use them.

Q. I know, I appreciate that. Now, that gets right down to this point: Then I take it you would have taken the

Phillips figures plus your own figures since 1935 and added them together and then added that to your remaining reserves on August 1, 1939 and you would have gotten the same figure, wouldn't you?

A. Well, now, aren't we getting a calculation and a summation mixed up?

Q. No, I don't think so. Maybe I can make it a little more clear to you. I have been trying to save time and take shortcuts. I'll break it up into sentences. All right, we'll take the Phillips production of—I mean the Phillips estimate which you have used here which is 4,883,680,740—somebody add that for me as we go along—up to August 1, 1935, and then we'll take your production figures as you have arrived at them since August 1, 1935 which is 2,450,370,036. Both of those are Mcf.

Now, the product of those two are what? That is, the sum is what? —All right, the sum of those two, someone tells me here, is 7,263,978,779. Now, that would have been your production figure as related to your pressure decline, wouldn't it?

A. From the beginning to—

Q. From the beginning to 1939, August 1, 1939.

A. If that figure is right, yes.

Q. All right, then, you have got your production per pound decline pressure drop; you have taken your decline over that period, weighted as you have weighted it, divided it into that 7,263,978,779, plus, Mcf., and you would have gotten your production per pound drop in pressure, wouldn't you?

A. That's right, taking into consideration all of the factors including your acreage.

Q. Then you would have multiplied back by 430, wouldn't you, to get your original zero pound content of the reservoir or the quadrant, or whatever you were working on. In this case it would be the reservoir.

A. In other words, we are now talking about taking the production from the beginning to 1939?

Q. That's right, 1939.

A. And arriving at a factor there instead of using the latter part.

Q. That is it exactly.

A. I think in general—I think that is a true statement.

Q. All right, then you have come out—

A. If you were sure of your original data, or could be reasonably sure.

Q. Oh, yes, I understand that. All right, now, suppose that came out in round figures, to make it easier to keep in mind, 29 billion Mcf., when you multiplied back by 430. All right, when you made your original estimate of remaining reserves in 1939 you would still have had approximately—these are round figures—22 trillion remaining reserves, wouldn't you?

A. I think that's right.

Q. That's right. The difference calculated, we'll say, is 7 trillion, but the figure that you based the calculation on was also 7 trillion, wasn't it?

A. Under the conditions you are using, that is right.

Q. Under the conditions that I named. You based your calculation on 7 trillion, didn't you?

A. Under the conditions you mentioned, that's right.

Q. That's right, so, therefore, your calculations, right or wrong, would have to check with that method of checking, wouldn't it?

A. Under the assumption you are making, that's right.

Q. All right, have I made an unfair assumption?

A. I wouldn't say you had made an unfair assumption, but in this particular case and under the method that we have used, we could not arrive at the figure according to that method, because it could not—this production we are talking about prior to 1939 is a lump sum thing and could not under any conditions be properly allocated to the areas from which it came. In other words, it is a lump sum figure rather than a figure that can be properly distributed to the areas.

Q. I understand you could have broken it down had you been sufficiently interested to have gone back—

A. No, it couldn't have been done.

Q. Well, why couldn't it?

A. Well, that is a lump sum figure.

Q. All right, I don't know that that is so important anyway.

Now, this is the whole thing about it, Mr. Hammer: Let's assume a situation where you do have accurate figures from the beginning; you use those accurate figures as related to

your pressure decline. In other words, you divide your pressure decline into those accurate figures and you get so many billion feet for each pound loss in pressure; we multiply that back by 430 and get the original content of the reservoir at zero pounds well head; then that figure that you have used as a basis of that calculation, whether it is 7 trillion, whether it is 10 trillion; or whether it is 5 trillion, or whatever it is, is a constant figure in there, isn't it?

A. If you assume a theoretical proposition where you—

Q. I am not assuming a theoretical proposition, I am assuming a situation where you do have accurate records from the beginning, that's all I am—

A. As far as the Texas Panhandle field is concerned, it amounts to the same thing. It is a theoretical thing because you didn't have that data.

Q. If you want to call it theoretical, then we'll call it that, but that figure which you utilized to determine original content as well as remaining reserves, is the same figure, wasn't it? It is the only figure you had.

A. Yes, that is true.

Q. So when you added in the one case to original reserves to get original and deducted it in another from original content to get remaining reserves, the thing has got to balance one thousand per cent if you made your multiplication and division correctly?

A. If you did that, and not subject to any further check, I think that is true.

Q. That's right. All right, then you at least agree with me that on my theoretical figures here, as you prefer to call them, that you are comparing similar things and neither certainly could be a check upon the other since they are the same in both cases?

A. Under that sort of a condition I think so.

Q. That would be right?

A. I said it would.

Q. I beg your pardon, I didn't quite get it.

Then, if we assume for the sake of argument, which is a matter that, of course, will have to be determined in this hearing among others, that the pressure decline method does not operate properly in the Texas Panhandle field and gives you an erroneous figure, then the check which we have used here would not disclose the error, would it?

A. Under the method that you have set up, that is right.

Q. That is right. All right. Now, you have already stated, I believe, Mr. Hammer, that you did not consider any of the early estimates reliable; that is, estimates of production up to August 1, 1935.

A. In general that is true.

Q. Well, I take it that follows for the Phillips, or does it? Do you make an exception as to the Phillips?

A. That is simply a general check. I am not certain of it. No one can be certain of it but the position I took there was this: that if there is anybody operating in the Panhandle field that should have a fairly accurate check, I don't know how accurate it is, it would be the Phillips Petroleum Company.

Q. How about Canadian River? Don't you think we are pretty good, or not?

A. They're pretty good operators, I think.

Q. That's right.

A. The only thing is, though, that their interests are not scattered so thoroughly over the field and they are not in the same line of business in a big way that the Phillips are.

Q. But if the Canadian River had tried awfully hard over a period of years to get accurate figures on the field, you would think that they are entitled to some consideration, wouldn't you, Mr. Hammer?

A. Well, yes, perhaps some, but not as much as an operator where they had been operating in all phases of the industry right from the beginning.

Q. Well, suppose Canadian River had put more time on it than Phillips had, would you still think that bigness ought to control over the little pebble on the *beech*, such as Canadian River?

A. Not that, but the point is that—I remember very well at one time the Phillips Petroleum Company had the largest number of men employed in—what they call scouts, watching every conceivable condition throughout the field—the largest number of any company in there, and talking to these fellows, they admit that while theirs is the best that they can get, it is a long way, one way or the other, from being an exact figure.

The witness further stated that he could not be certain

about the Phillips figure for production prior to August 1, 1935, and that, as a matter of fact, Phillips admits that the figure is a long ways from being exact.

The witness stated that the east Texas Panhandle field was much more nearly depleted than the west Texas Panhandle field, but he did not think that operators in the east portion of the field would move to the west portion of the field for a supply of gas, but would more likely go to Hugoton, Kansas.

Witness further stated that he knew very little about conditions in the west Texas Panhandle Field with respect to shifting production from the eastern areas into the western areas, and that he did not know that as gas pressures became low along the northeastern flank of the structure that there was not enough gas produced in those areas for carbon black, and stated also that he did not know whether carbon black production in Moore County had increased since 1935. He just didn't check the carbon black production.

The witness further testified on recross examination (Vol. 61, pp. 8582-8588) as follows:

* * * * *

Q. All right, you don't know. Now, Mr. Hammer, you made the statement on your redirect examination on Saturday that every segment between your isobar lines contributed equally to the total average for each particular quadrant; that is, total weighted pressures for each particular quadrant.

Mr. March: I object to that. The question I asked was, on your hypothetical illustration of isobars every ten pounds on a hypothetical situation, not on this map up here.

Mr. Keffer: Your question was hypothetical.

Mr. March: Why, your original question was hypothetical and my questions here are hypothetical.

The Witness: May I explain what I think that was?

Mr. Keffer: All right.

The Witness: The only place where I utilized that expression as I remember was where we had that container

and were taking out a half of the gas and we got 200 pounds and 400 pounds and the point there was that they both contributed equally.

Mr. Keffer: I think that came later. I could be wrong about it, but I am just speaking entirely from memory. I haven't checked the record on it, but as I recall from your cross examination, I went into some detail and used Quadrant 1 of Potter County, not a hypothetical quadrant at all, Mr. March, but the actual quadrant with the isobar lines drawn on it just as Mr. Hammer drew them.

Mr. March: Oh, no, that wasn't the intention of the question at all. Here is what I really asked, if you want me to give it to you in the record to straighten it up. You will recall, Mr. Keffer, you said, "Let's assume that we have a quadrant with isobars on there all the way from 200 pounds to 400 pounds."

Mr. Keffer: That's right.

Mr. March: "And that you go in between 200, 210—" you recited the whole group in the record there.

Mr. Keffer: And which was Potter County Quadrant 1 as taken from his map.

Mr. March: I never used that at all.

Mr. Keffer: Those were the figures taken right off the map here.

Mr. March: Here is what I really asked him: The point was there that I was bringing out in the 400-pound segment that it contributes twice as much to the total factors as does the 200-pound segment, but each segment contributes equally to the average and you can read the record on that, and that is what I was bringing out.

Mr. Keffer: That's right. Now I want to take that up and see if it is. Now, a 400-pound segment—in fact, you have 430 in the southernmost segment of Quadrant 1 of Potter County—would contribute considerably more than the segment from 370, or 360 I should say, to 370 in the northeast corner of that segment, wouldn't it, simply because the pressures are greater; you have got a bigger multiple.

The Witness: It isn't comparable because you are leaving out a lot of other things there.

By Mr. Keffer:

Q. I am taking your segment here. By the way, before I forget it, I want to correct a statement. The 200 to 400 was not identical with the Potter County Quadrant 1. It runs, it looks to me like here, 360 to 435. There is that variation.

A. No, there is no 35 on there.

Q. I mean 430, I beg your pardon. Now, the higher the pressure in your quadrant—I mean in the segment, between isobar lines, the greater the, acre for acre—the greater acre for acre factor you would have for the—no, strike that. I'm getting a little balled up.

This is what I am trying to state: If you assume an equal number of acres in any particular quadrant—I mean in any particular segment of the quadrant, then the higher the pressure the greater will be the weight given to a particular segment?

A. No, they are all weighted out so that the segments contribute equally to the average.

Q. I know that is what you stated on your redirect Saturday. However, two or three days ago, after spending two or three hours on it, I think you finally said that a segment containing a thousand acres with 400 pound pressure would contribute just twice as much to your total aggregate figure as a segment of a thousand acres containing 200 pounds pressure, and we worked it all out to demonstrate it for your satisfaction.

A. That was your demonstration. As a matter of fact, the same statement would hold true there that while the 400 might contribute more, but when you come to the average of your 400 and your 200, they both contribute equally.

Q. Oh, I'm glad you made that statement. Then they both contribute 300, is that right—4 and 2 is 6, divided by 2 is 3.

A. That's right.

Q. All right, but in getting that 6 you multiplied your 200 by a thousand acres, you multiplied your 400 by a thousand acres, didn't you? You had, say, 400,000 in one, if it figures out that way, and 200,000 in the other, being 600,000 in all with an average of 300,000.

A. In your theoretical proposition, that is true, but as a practical matter in this Quadrant 1 you are talking about, or any other quadrant, it is not applicable.

Q. All right, now, just why isn't it?

A. Well, you are leaving out all of those intervening pressures there.

Q. I know, and that is what you said the other day.

A. I still say as far as I am concerned there is no use to argue about that.

Q. So we took time off, I went—I took segment after segment with 10-pound intervals and had you figure it all out and then had you compare the 200 with the 400 and it showed for the same acreage that the 400 was contributing twice as much to your total down there as the 200 was didn,t we?

A. Yes, but these are all weighted averages.

Q. I know, but if you will just follow me—but the 400 did contribute twice as much as the 200 to the product from which you obtained the average?

A. Yes, but each contributed equally to the average.

The Trial Examiner: How could they?

Mr. Keffer: How's that?

The Trial Examiner: I asked Mr. Hammer how could they.

The Witness: Well, if you—

The Trial Examiner: Assuming, now, that your acreage is the same.

The Witness: Well, take—

The Trial Examiner: I think what you have in your mind, Mr. Hammer, is that by taking your 10-pound steps the degree of difference is not so great as when you jump from 200 to 400, but it remains that if your acreage is the same that your acreage with the 400 pounds pressure contributes twice as much to your total as the acreage with the 200 pounds pressure

The Witness: Isn't it also true that if you strike an average, they both contribute equally?

The Trial Examiner: They may contribute equally in this way, that—

Mr. Spencer: They both give all they have.

The Trial Examiner: That's just the point. Isn't that the point, Mr. Hammer?

The Witness: Well,—

The Trial Examiner: But you feel that because you have taken these 10-pound steps that your weighted average brings the proper average, but nevertheless, it is also true, is it not, that your acreage with 400 pounds pressure contributes twice as much to your total as the acreage with the 200 pounds pressure?

Mr. March: Mr. Examiner—well, pardon me, you're not asking me the question.

The Witness: Well, I think perhaps the best way to answer that is this: We'll go back to Mr. Keffer's cylinder, and you take out—assume that cylinder was a thousand acres, and under his theoretical setup, you took out 1500—15,000 cubic feet and you had a pressure left of 200 pounds. Now, that 15,000 cubic feet was half of the gas. There also remained in that one-half of the gas, but at a changed pressure.

Now, the same amount of gas was in that container, but a changed pressure from that which had been drawn out of it; so the remaining gas in that contributed equally to the gas withdrawn.

Mr. March: Mr. Examiner, in your question did you assume that there would be more 400-pound acreage than 200-pound acreage?

The Trial Examiner: No, assuming the same acreage, a thousand acres.

The Witness: Does that clarify the situation?

The Trial Examiner: It doesn't clear it to me, but you can go on. Go ahead, Mr. Keffer. Pardon me.

The witness again stated that there was a great deal of unmetered gas in 1935 and 1936 which was not reflected in his production figures for that period, but that all of the gas shown by the Railroad Commission report for 1937 was metered gas.

The witness further testified on recross examination (Vol. 61, pp. 8590-8603) as follows:

A. I don't know how much of that gas from gasoline plants was going into the air. I do know that, except a lot of gas that was wasted, that the gas that went to the gasoline plants was, I think, without exception metered gas. The point is, though, that what I wanted to illustrate there was that although this order came into effect in 1935 and the law came into effect—I simply wanted to use this as an illustration—that it took from 1935 way over in to 1936 and then declining on beyond that, to the point where the Railway Commission had got more or less control of the situation. Now, during that early time while all of the gas to the gasoline plants—I think out of necessity was metered, at least the greater part of it was, there was also during that time a continued great wastage of gas that wasn't metered because control had not been had of the situation. Now, that's all I had in mind to illustrate.

Q. All right, then, to clarify the record, the chart which you referred to in the Railroad Commission report of 1937 and the observations you made with respect to the total volume of gas that was going into the air, had nothing to do with your estimates.

A. No, except that I wanted to illustrate that the Railway Commission, although it took some time after they had put in both of their orders, before they got control of the situation and during that time, outside of the gas that was metered, there was a very large wastage of gas.

Q. But all of the gas shown on the graph which you are referring to was metered gas?

A. I think that is true.

Q. In other words, they couldn't have shown it if it hadn't been, could they?

A. The point I wanted to make is to illustrate that they didn't get control of the situation.

Q. Well, I don't hardly see how that has anything to do with the problem. The impression I had, Mr. Hammer, and that is the only reason I went into it, was that you were referring to that large volume of gas as an evidence of great volumes that you had not taken into account in arriving at your estimate which would have a tendency to make it more conservative.

A. I think if you will go back over that, I attempted to correct that impression but the questions were shot at me so fast I was never given an opportunity.

Q. Well, I am sorry that I misunderstood. The whole point is that the gas you are referring to in the graph in the 1937 report was metered gas?

A. That is true.

Q. And, consequently, was considered in your estimate?

A. Yes, it was, but as I said, the thing was that it was during that period that there still was great wastage that was not metered gas.

Q. Now, as to the gas that was wasted into the air, unmetered gas, that was wasted during that period, do you have any idea about how much there was of that?

A. I haven't been able to check it out accurately. Sometimes the reports of the Commission give you figures that you can take off and sometimes the way they are set up they are so confusing that at least I haven't been able to interpret accurately what they mean.

Q. Well, all right. Now, you used Quadrant 3 of Potter County, Mr. Hammer, in constructing the curve which you have in your Exhibit 180, I guess it is.

A. Yes.

Q. Now, why did you pick out Quadrant 3, Potter County, upon which to construct that curve?

A. No particular reason that I remember. We just said, "We'll take Quadrant 3. It's as good as any."

Q. Take what?

A. We said, "We'll just take Quadrant 3 for example," and that's all.

Q. Did you try it on any of the rest of them before you selected Quadrant 3?

A. No, I'll tell you, we didn't have time to do a lot of trying.

Q. I see.

A. We just picked out a quadrant and worked it through.

Q. Now, the fact that Quadrant 3 has had a rather even decline in pressure would tend to make your line which you have drawn on the graph a straight line where some of the rest of them wouldn't, wouldn't it?

A. I don't think that is true.

Q. Well, isn't that obvious?

A. No, I don't think it is even obvious.

Q. Oh, it isn't. Well, tell me why it isn't, then.

A. Well—

Q. I say, if your pressure decline in Quadrant 3, Potter County, was more or less on a straight line, of course, when you plot it out it would give you a straight line, wouldn't it?

A. Well, the same thing would apply to any of the rest of them.

Q. If you had another quadrant that didn't plot out on a straight line, but a crooked line, with a curve tending to go down, down, down, much more than Quadrant 3, Potter County, you would have a harder time at least getting a straight line out of it, wouldn't you?

A. No, we are coming back to that old curve idea of yours about plotting pressure drop against time and that, it seems to me at least, is not applicable to a determination of gas reserves.

Q. Well, if you will answer me just this one question, we'll leave it. If you could pick out a quadrant where the decline did give you virtually a straight line and I could pick out a quadrant where the decline didn't give virtually a straight line, why, then there would be something there, wouldn't there?

A. Well, what do you mean, "be something there"?

Q. You would have a straight line in your case and a crooked line in mine.

A. No.

Q. Wouldn't we?

A. Of course, if you drew them you might, but not if I drew them.

Q. You can always draw a straight line even though it's a crooked one, is that the point?

A. Well—

Mr. March: I object to this line of questioning. We have gone far enough, I believe, with this fun. I'm having a lot of fun out of this myself.

By Mr. Keffer:

Q. As I understand, you didn't draw any curves on any of the rest of them?

A. Oh, yes, on two or three, just as a test, sure, but I

couldn't go ahead and project a curve on every darn group.

Q. How's that?

A. There is no necessity of going ahead and projecting a curve on every group. The only reason one was picked out was by way of demonstrating the method used.

Q. That's right. Of course, just as between you and me, we don't agree even on the one you picked out. That's clear to both of us, I guess.

A. You mean as between you and I?

Q. Yes, that's right.

A. I don't think—that isn't pertinent to the question.

Mr. Keffer: The only point, Mr. Examiner, I think the record is clear on it—I have contended that Mr. Hammer doesn't have a straight line even though he has drawn one, that he has ignored the points in order to draw a straight line and he says he hasn't, and there the record stands and there I am willing to leave it.

The Trial Examiner: Are you going to leave it there, Mr. Keffer?

Mr. Keffer: Yes.

The Witness: That's all right with me.

Mr. Keffer: All right. Now we'll go to something else.

Q. Now, Mr. March went into some detail with you on the matter of the Lefors area in Gray County, Mr. Hammer, with respect to the drainage question, do you recall that?

A. Well, there was some discussion about that, yes.

Q. That's right. You stated that the Lefors area had a very low pressure existant at this time.

A. That's right.

Q. And I believe either you or Mr. March stated, one or the other—I am pretty sure it is in the record—that there was no more reason for gas to drain from the Canadian River in the low pressure Borger area than it was for the Lefors to be repressured from the surrounding—

Mr. March: Let's get the record straight. I tried to get the witness to make that statement.

Mr. Keffer: Now, you did make the statement, I believe, also, Mr. Hammer, that if there had never been any produc-

tion in the Panhandle field except from the oil wells and other gas wells, some of them would be gas wells but primarily oil wells along the northwest flank of the structure, that there would today be great areas in the field that have virgin pressures, is that right?

A. Yes, I made that statement.

Q. And did you or did you not make the further statement that those pressures would always remain high in the absence of production, back in the higher pressure areas?

A. No, I don't recall making such a statement.

Q. All right, you do think, then, that even though there might have been high pressure areas in portions of the field that the production—heavy production along the northeast flank which created low pressures in that area, would in time have eaten its way back and destroyed the high pressures back to the southwest, even though there had never been any production from that area?

A. There the question of relative time comes in. Let me answer that this way: Ordinarily I wouldn't even have referred to the thing, but in this hearing so far I have heard so many judgment figures put in that I didn't see where it would do any harm for me to put in a judgment figure. Now, that was simply a judgment figure.

Q. And you yourself wouldn't want to rely much on it?

A. Well, that is my judgment, just like it is any man's judgment, and to go ahead and elaborate on it, I don't think it is necessary to elaborate on a person's judgment on a problem of this kind.

Q. Even though the judgment is bad?

A. I think it is better than some other judgments that have been put in this hearing.

Q. Well, if somebody expresses a bad judgment, still since it is his judgment, should it stand there at its face value?

A. Yes, it is his judgment, whatever it is.

Q. All right, now, when you did express that judgment, though, you were expressing some judgments about drainage, weren't you, unavoidably?

A. Yes, certainly.

Q. Now, you state that you made no study of drainage, and where it gets into other portions of the field you say you just can't answer because you haven't studied drainage.

A. That was just a general statement that anyone could go up there and study this thing a while and arrive at a judgment and say, "That's my idea."

Q. That is the very point I am coming to. Since it is a judgment figure as you have stated and not based upon any study, then you wouldn't expect the Examiner to take it as evidence. Now, isn't that a fair statement of your position?

A. Well, I think this, to be absolutely frank with you, that after having worked approximately two years on a program of this kind and whether or not you made a study—a particular study of drainage, you simply got certain impressions during that time of conditions that exist. You couldn't help it and I got a certain impression about a lot of things that aren't included in my estimate of reserves.

Q. I understand, but you, as an engineer—and an engineer must not make too many mistakes, to say the least of it—as an engineer, would not ask the Examiner or the Federal Power Commission to take your offhand impression as to what would happen to this high pressure?

Mr. March: Now, Mr. Examiner, at the very beginning of this cross examination he asked him if he made any special study of the drainage problem and the witness said no, yet Mr. Keffer is asking him what his opinion would be.

Now, Mr. Keffer has asked for his offhanded judgment and he has got his offhanded judgment and I will say that can stand in the record for what it may be worth in the Examiner's consideration. That's all anybody can do. If he is going to—maybe he will prepare an exhibit in rebuttal to your drainage exhibit, I don't know what he will do, but this drainage problem has nothing whatever as a separate problem to do with the exhibit under consideration here. The witness has said he has taken it into consideration in his isobars automatically. I object to any further questioning along that line, Mr. Examiner.

Mr. Keffer: I feel very much gratified that I have been referred to in a general way as Mr. March. Now, Mr. March said that I got that question out of the witness. As a matter of fact, it was Mr. March on his redirect examination, and that is the only reason that I am going into it. I didn't elicit it. Mr. March on Saturday morning in his redirect

examination got an answer from Mr. Hammer, if my memory serves me correctly, to the effect that if there had never been any production except along the northeast flank of the Borger area that great areas in the Panhandle field today would have virgin pressure.

The Witness: I think, Mr. Keffer, that I can clarify that.

Mr. Keffer: Sir?

The Witness: I think I can clarify that.

Mr. Keffer: All right.

The Witness : And I believe my clarification of this will relieve all stigma from either you or Mr. March. I volunteered it myself and no question was asked.

By Mr. Keffer:

Q. But Mr. March was asking the questions when you volunteered that, isn't that right?

A. Yes.

Mr. March: But you already asked a dozen questions about the same thing.

The Trial Examiner: Perhaps we can strike it and go on.

The Witness: As far as I am concerned, it can be struck out. I wasn't asked a question. I volunteered it, as I remember.

Mr. March: Let him stand on his own statement in the record.

Here it is on Page 8523 in the record:

"I would say, as I have tried to say before, and on which point I have a very definite impression, that if it had not been for the development of gas back from these oil fields and if the gas withdrawals from the oil fields alone had been taken—had been the only cause of pressure decline, a great part of the entire Texas Panhandle field in my opinion would still have its original pressure."

The Trial Examiner: Is that the statement you are referring to?

Mr. Keffer: That's right. That is the one I was examining him on.

Mr. March: We will agree that that may be stricken if there will be no more cross examination about drainage here in regard to this exhibit.

Mr. Keffer: I'm not going to make any agreement such as that.

Mr. March: All right. We object to any further cross examination about drainage.

The Trial Examiner: Well, the situation, Mr. March, is that this did creep in on redirect examination and I can't cut Mr. Keffer off on cross examination.

Mr. March: All right, we'll leave this right here, then, as far as we are concerned. We'll let it stand like it is in the record.

Mr. Keffer: All right. It is in and out and in and out and now it is in?

Mr. March: Now it is definitely in as far as we are concerned.

Mr. Keffer: All right.

Q. Now, Mr. Hammer, we can finish that in just a statement or two, I think. As I understand, you have already stated that that is based on no particular study on your part, purely an offhand impression.

A. That's right, a judgment figure like Mr. Rhodes put in and these others.

Q. But there was no study behind the judgment?

A. That's right, the same as in the other case.

Q. It's just like somebody out in the street or a tool dresser or somebody else might make the same statement, it gets down to about that point?

A. It is comparable to statements that were put in by Mr. Watson and Mr. Rhodes.

Q. By whom?

A. Mr. Watson and Mr. Rhodes' judgment figures.

The Trial Examiner: Never mind that, Mr. Hammer.

The Witness: All right, strike that out.

Mr. March: The question was asked whether or not it

was just like a tool dresser—in regard to a tool dresser in the oil field. He asked for that sort of an answer.

The Trial Examiner: Perhaps that question was out of place.

Mr. Spencer: I suggest that they both be stricken and let Mr. Keffer start again.

Mr. March: That is satisfactory.

The Trial Examiner: Very well.

The witness then again referred to the container examples and solved the problem contained in Exhibit 189 correctly by going back first to the original volumes and then using original volumes as the weighting medium and not the surface area, and also his computations were based on the known original content. He said it was not necessary to know this in estimating the future reserves in the Texas Panhandle Field.

The witness was then asked to solve the problem just as he did in estimating reserves in the field, which was as follows (Vol. 61, pp. 8607-8648):

Q. Now, Mr. Hammer, on redirect examination you worked one of the problems that I gave you but let the other one go unsolved. The other one was this, referring to Exhibit 189. I gave you a situation—

A. Just a moment until I get the exhibit out.

Q. The problem was this, take each of the three quadrants shown on Exhibit 189, and you had this problem: From Quadrant A there had been produced 15,000 cubic feet and there was 200 pounds remaining. In Quadrant B there had been produced 5,000 cubic feet and there was 300 pounds remaining. In Quadrant C there had been produced 2,000 cubic feet and there was 320 pounds remaining. Your original pressures in all three quadrants, your virgin pressure, was 400 pounds. Now, I want you to solve that problem just precisely as you solved the problem on the Panhandle field, with those known factors.

Mr. March: I object to that question: The witness has said a dozen times that these three containers aren't comparable to the detailed method with which he solved the problem. He can apply the principles he applied to the

whole field but to say he went through every movement he made in computing the reserves of the entire field would be to put the hypothetical to the real on which there has been an argument and haranguing about that for at least a half day on that very proposition.

Mr. Keffer: Let him apply the principles that he applied to the field.

Mr. March: In any case, it is clear in the record already that he is not going to be drug into a statement here that this is the field here, these three containers.

The Trial Examiner: I think the record is quite clear on that, Mr. March, and as I understand it, Mr. March, it is the mechanics of the calculation that Mr. Keffer wants.

Mr. Keffer: That is it exactly.

The Trial Examiner: Well, now, Mr. Keffer, didn't he work that very same problem for you on cross examination?

Mr. Keffer: He did, and he got an erroneous—I say, "an erroneous" answer, he got an answer of 69,000 plus where the answer only ought to be 60,000.

Mr. Spencer: 60,000.

Mr. Keffer: 60,000, yes. On redirect he didn't take up that particular problem but he did take up another one, and I am wondering if the same principle he used in the other one would apply to this one.

The Witness: I have that problem worked out.

By Mr. Keffer:

Q. How's that?

A. I have it worked out.

Q. Just like you worked it on the field?

A. Just as I would apply it to the problem you submitted.

Q. No, just apply the same principles you applied on the field.

Mr. March: Mr. Keffer is trying to force this witness to say that he is making the application as if he were making it to the field. Now, he will work the problem out—

The Trial Examiner: I think it is clear, Mr. March.

The Witness: Now, this is the problem where we had three cylinders?

Mr. Keffer: Quadrants.

Mr. March: Cylinders, we'll call them.

Mr. Keffer: Go ahead.

The Witness: —of different sizes, but with unknown content.

By Mr. Keffer:

Q. That's right.

A. But which have known original pressure.

Q. That's right.

A. And known pressure after the gas had been withdrawn.

Q. That's right.

A. 15,000 cubic feet withdrawn from Cylinder A; and the pressure gauge shows 200 pounds instead of 400 lbs. There has then been a decline of 200 pounds against a withdrawal of 15,000 cubic feet, or 75 cubic feet for each *pound* decline. 200 times 75 equals your 15,000 cubic feet. One-half of the pressure has been used; so there must be 200 pounds remaining or a volume of 2 times 15,000 or 30,000 at original pressure of 400 pounds. From Cylinder B—

Q. Now, wait just a moment. You are to apply the same principles you applied on the field and that is weighting them all in one against the other, Mr. Hammer.

A. That's what I'm getting to, but you must let me go through and arrive at this thing.

Q. Is that the way you did the thing on the field?

A. According to my own method of determination.

From Cylinder B there have been removed 5,000 cubic feet with an original pressure of 400 pounds and the metered pressure of 300 pounds. In that case one-fourth of the pressure, or one hundred pounds had been lost; then 5,000 cubic feet divided by 100 pounds equals 50 cubic feet per pound of pressure drop; then a hundred times fifty is 5,000 cubic feet. The remaining pressure is 300 pounds; then 300 times 50 is 15,000 cubic feet remaining. Then 15,000 cubic plus 5,000 cubic feet equals 20,000 cubic feet in Cylinder B at original pressure at 400 pounds.

In the case of Cylinder C there was also an original pressure of 400 pounds, the volume unknown, 2,000 cubic feet of gas was the remaining pressure gauge—no, and the pressure gauge showed 320 pounds or a decline of 80 pounds from the original pressure of 400 pounds. Then 2000 cubic feet divided by 80 pounds is equal to 25 cubic feet per pound pressure decline. 80 times 25 is 2,000. The gas withdrawn is then equivalent to the pressure loss. 80 pounds equals one-fifth of the original pressure, four-fifths or 320 pounds remain. 320 times 25 cubic feet equals 8,000 cubic feet which added to the 2,000 cubic feet withdrawn gives the 10,000 cubic feet originally in Cylinder C at 400 pounds.

We are back now to the point of where we know the original volume. We know the original pressure. It then resolves itself into this: We have three cylinders, one of 30,000 cubic feet, one of 20,000 cubic feet and one with 10,000 cubic feet or 60,000 cubic feet in all. From one—from the —well, I think I'll refer to these as A, B, and C, and that will keep it straight.

From Cylinder A we drew 15,000 cubic feet or the equivalent of withdrawing 15,000 feet from them. From Cylinder B we drew 5,000 cubic feet and from Cylinder C we drew 2,000 cubic feet. Now, all cylinders have their original volumes, but at a reduced pressure; hence, to properly solve the problem we have to weight each original volume against the reduced pressure as follows:

30,000 times 200 equals 6,000,000;

20,000 times 300 equals 6,000,000; and

10,000 times 320 equals 3,200,000, or a total volume pound factor of 15,200,000. Now, 15,200,000 divided by the 60,000,000 cubic feet originally in all three cylinders gives the weighted average pressure.

Then, 400 pounds minus 253.33 is equal to 146.666, or the weighted average pressure decline. The total gas withdrawn against this pressure decline is 22,000 cubic feet, which divided by 146.666 equals 150 cubic feet per pound pressure decline. Then 400 pounds times 150 cubic feet equals 60,000 cubic feet, the original gas in place at original pressure.

Q. All right, Mr. Hammer. You took each quadrant

separately and worked back to get its known content; then you took the known content and averaged it in, didn't you, to get the correct answer?

A. Let's see, now, you mean—

Q. In fact, you already had the correct answer way back in the middle by taking each one of them separately, didn't you?

A. No, I didn't. Taking each one of them separately I just had—

Q. Now, then, you got back to the original content and then you averaged the known original content, didn't you, of each quadrant?

A. No, of each cylinder.

Q. All right, of each cylinder, isn't that right?

A. No, in weighting them I weighted them all together.

Q. I know you weighted them all in on a volume basis and not on a pressure basis on this case here, yes.

A. On both a volume and pressure basis.

Q. Now, let's take that a step further and do it. Now, that isn't the way you did it in the Panhandle field, is it, or in any particular quadrant of the field, as you have explained many times?

A. Eventually we arrived at the future production, the future reserves, and in arriving at the future reserves by the method we used, it was not necessary to know the original content.

Q. That's right, and shouldn't be necessary here to know it, should it?

A. Well, it was my impression that you wanted this same figure back to original.

Q. I want the same principles that you applied in the Panhandle field with known pressures and known production records and known original pressures and see if you came back to the right answer, applying exactly the same principles you did on the Panhandle field, and that way we can test your principles as applied to the Panhandle field. That's all there is to it.

Mr. March: Is there a question pending?

Mr. Keffer: Yes, an explanation by Mr. Hammer.

Mr. March: What do you want him to explain?

Mr. Keffer: I want him to solve the problem exactly as

he solved the reserve problem on the Panhandle field and not in some other way.

Mr. March: This is his problem, of the Panhandle field. He has solved the problem on the Panhandle field here in his exhibit. He has testified time and time again as far as these three cylinders are concerned. That's just a hypothetical problem. Now, if you want to know his result of the entire field on the pressure decline method—you have been looking at this exhibit now for a week here, and you can look at it. We object to any further questioning along that line.

By Mr. Keffer:

Q. Mr. Hammer, let us take any quadrant—I am pointing to Quadrant 1 in Potter County, and we'll say—we'll say "cylinders" as a *compplimeni* to you, and Mr. March, on the exhibit 189 that you were looking at. Let's say those three cylinders constituted one quadrant all interconnected.

Now, I want to get the weighted average pressure in that quadrant just as you did on Potter County 1.

Now, what you did there, as in all quadrants, was to take the area in each segment between each isobar line and multiply it by the pressure, wasn't it?

A. Yes, that is right.
Q. And you added them all up together, didn't you?
A. That's right.
Q. And then you divided by the acreage?
A. That's right. It gave you a—
Q. Weighted pressure?
A. That's right.
Q. Now, do that on this problem, just precisely that way.

Mr. March: I object to that. That has all been gone over before, Mr. Examiner. Even Potter County 1 was mentioned in this hypothetical situation. He has worked his hypothetical problem here for him and now he wants through implication and other direction, he is attempting to lay down a hard and fast rule covering this exhibit here, as a matter of fact where the exhibit speaks for itself.

Mr. Keffer: There is no question about the method. He is applying that method precisely to this problem that I have given him here, that's all there is to it, Mr. March.

Mr. March: He is computing the reserves in each one of these, in each one of—the reserves for each one, that's all been gone over.

The Trial Examiner: The objection will be overruled.

Mr. Keffer: Sir?

The Trial Examiner: The objection will be overruled.

Do you recall the question, Mr. Hammer?

The Witness: You want those weighted in?

By Mr. Keffer:

Q. Yes.

A. You mean to find the—

Q. Weighted average pressure just as you did on the Panhandle field.

A. I am assuming that each of these areas as we originally assumed is of equal size in acres.

Q. That's right.

A. Then, of course, it would be equivalent to multiplying each of them by one.

Q. That's right.

A. Which would give your acre pound factor.

Q. That's right.

A. Then I divide that—no, I take the summation of those acre pound factors and I divide it by the three acres which gives 273.33 as the weighted pressure.

Q. As the weighted pressure of the three?

A. Of the three.

Q. That's right. Now, you had 400 pounds pressure to start with, didn't you?

A. Yes.

Q. And 273 1/3 from 400 gives you 126 2/3 left as your weighted decline in pressure, doesn't it?

A. Covering that problem, yes, that is the difference.

Q. You have an average weighted decline of 126 2/3 and you have a total production of 22,000, don't you?—15 in A, 5 in B, and 2 in C?

A. Yes.

Q. All right. Then to get your production in pound decline you would divide your decline in weighted pressure, which is 126 2/3, into 22,000, wouldn't you?

A. By that method of calculation—if I have made my

calculations right, it would come out approximately 107—is that right?

Q. 107—173, isn't that right?

A. I hadn't carried it on out.

Q. Well, you can look at it. It ought to be 173.

A. Wait a minute, it is 107.

Mr. Spencer: Oh, no, it isn't.

Mr. Keffer: Oh, no, it wouldn't be 107.

Q. 173 cubic feet of production per pound decline in pressure as weighted, is that correct?

A. That is the way it figures out in that problem.

Q. Then to get your original content you would multiply that 173 by 400, wouldn't you?

A. Yes, on that problem.

Q. And that would give you a total of 69,200, wouldn't it, cubic feet original?

A. Yes, that comes back to the old thing, though, that we are only dealing with three of them here and there is an infinitesimal number of them in the field.

Q. Now, it is admitted, of course, that we are only dealing with three. Now, the way you have those averaged, those three, is just the way you averaged 789 or 10 in Quadrant 1, Potter County, isn't it?

A. Yes, against the acreage.

Q. And if you had only three quadrants—I mean, segments in that quadrant, then it is this—certainly as to the number, it would have been identical, wouldn't it?

A. Yes, but that's just the point. They weren't identical and they weren't—they aren't identical.

Q. Sir?

A. They weren't identical and they aren't identical, because if you go ahead and take enough of these containers or segments you eventually get to your—to the same figure. In other words, it will check out. It is not synonymous at all.

Q. I will ask you just one more question, Mr. Hammer:

If the principle would work on 10 it would work on 3, wouldn't it?

A. Yes, but you go on through with that to an infinity of containers and you will gradually approach—you will eventually approach a true figure.

Q. Well, now, as a matter of fact, I have given you in this assumed problem figures that do not vary as widely as the conditions in the field vary. I think you admitted that the other day when we were on it.

A. Well, that is an assumption. I don't think you can fairly draw a parallel.

Q. You don't think what?

A. I don't think you can draw—you can fairly draw a parallel.

Q. Well, the variation in pressure here was only from 200 to 320 and it is far more than that in the field, isn't it—pardon—more than that in practically every other quadrant up there?

A. If you are looking over a wide area proposition, yes, but of a local condition, no.

Q. Well, do you refer to a quadrant as a local condition?

A. Well, the term is relative. What I am talking about is a field-wide proposition without local areas. There are so many factors there, when you consider the thing as a whole, that aren't applicable local areas.

Q. Well, how did you take those different problems into consideration?

A. Just as I have previously, by grouping and by process of eliminating everything except adjacent areas eventually cover the whole field.

Q. That's right. Well, isn't that just all there is, haven't you gone the whole route now?

A. No.

Q. All right, what—

A. Oh, we are coming back to the number of these cylinders that you have to weight.

Q. Weight in—well, you say, then, that Boyle's law will not work on three cylinders but will work on ten, is that the point?

A. No, I made no such implication.

Q. What did you mean to say, then?

A. Just as I said before that you take enough of these things, of the so-called cylinders, and eventually weight them out properly as against the acreage and you will approach a true answer and eventually get it.

Q. How many do you need?

A. Well, I don't know. I never figured it was necessary to figure out how many you would need.

Q. Well, do you think five would do the job?

A. I don't know.

Q. Would you like to try it on five? Well, we can both do that some time when we have more time. I am willing to let the record stand on that as it is, Mr. Hammer.

Now we'll go on to one or two other matters. You made the statement—I'm not sure whether it was Saturday or whether or not it was some time during the course of your testimony—yes, I believe it was Saturday—that pressures were taken on wells sometimes before they had a chance to build up.

A. Yes, I think I made that statement.

Q. Now, in what kind of formation does that most likely occur?

A. Well, in general in an area of low potentiality I would say.

Q. That's right. The reason they don't build up is because of the tightness of the producing formation and maybe permeability or both?

A. And draw gas out rapidly and it takes a long time to get it back.

Q. It takes a long time to build it back up, doesn't it?

A. Yes.

Q. Now, does that indicate that those areas aren't as productive as some others?

A. No, not necessarily.

Q. What does it indicate?

A. It just indicates an area of low permeability.

Q. How is that—just an area of low permeability, is that your answer?

A. Yes.

Q. Does that indicate to you that the areas around the well are rather lean?

A. Well, it just indicates that.

Q. If permeability and porosity vary directly, it would indicate they were rather lean, wouldn't it?

A. Well, I have stated before that while there is a general relationship you can't convert one to the other. They aren't similar. They are two different things entirely.

Q. What is going to happen when the production shifts to those particular areas, Mr. Hammer?

A. Well, several things may be. Among other things, the first thing they will probably do on all those wells is

acidize all of them to increase the permeability around the hole.

Q. They didn't seem to see fit to do that over in Gray County as yet, I take it?

A. I don't know as to that. I think there has been some of it done, but I don't recall exactly the locality.

Q. Then apparently it would work?

A. I wouldn't say that.

Q. Well, you have that Gray County Quadrant 2, I believe it is, or 1. It is one of the other, Gray 1 or 2, that for the last three years of your study there hasn't been a foot of gas produced from it, yet there were wells there, isn't that true?

A. I think that is true maybe. My remembrance of it—

Q. Yes, I think that is very definitely the record in that case; so they haven't been able to do anything about it, or at least haven't done anything about it, have they?

A. Well, I think it was partly a case of where there wasn't any immediate demand.

Q. Well, of course, they drilled the wells for something, I take it, for some reason.

A. Well, naturally they were looking for gas. Probably some of them were looking for oil, I don't know.

Q. All right, let me state it this way, then: Those areas that you are speaking of where your pressures have not built up, the pressures have all gone down so rapidly with the production of gas, haven't they?

A. Yes, I think that is probably true.

Q. As a matter of fact, that is the reason they haven't built up, isn't it?

A. It indicates—it would indicate a slow movement of gas.

Q. All right, then; if you go to withdrawing heavily from those areas, won't your pressures drop more rapidly than would be true in the more prolific areas?

A. Well, I would say there that what you would have to do would be to drill more wells in an area of that kind.

Q. Well, the more wells you drilled the still more rapidly your pressure would drop?

A. It would all depend on your withdrawals.

Q. How's that?

A. It would all depend on your withdrawals.

Q. Well, I know. Maybe we were together. If you had

100,000 acres here in this tight formation and you pulled, say, a hundred million feet of gas out of it over a period of time and the pressures dropped very rapidly and never did build up—

A. They eventually build up.

Q. I know, but they build up slowly and drop rapidly.

A. All right.

Q. Then, if you had a well on every section in that one hundred thousand acres, wouldn't they drop more rapidly and build up still more slowly?

A. No.

Q. Why not?

A. If you took the same amount of gas out of each well—

Q. Why doesn't it drop more rapidly if you only had one well in that wide area?

A. Because you would be distributing the take from one well rather than from one or two.

Q. I don't think you understood. I am assuming the same volume of gas out of each well, not out of the area.

A. Well, you had not stated that.

Q. Well, I intended to. I thought you misunderstood me, the way you answered it.

A. Well, that's a difficult question to answer directly for the reason that you don't know and I don't, and no one knows what those wells are going to be until they are drilled.

Q. Oh, I know. I mean that judging from the wells we have. That's the only thing we can adjust it by.

A. Well, there has only been one or two places where wells have had much production taken out of them. I don't feel in position to judge what would happen to the others.

Q. Well, assuming that the others were of the same characteristics as the one well that you predicate your opinion upon; then the more wells you had in a given area the faster would be your production drop. Certainly it wouldn't be any slower.

A. If you took an equal amount of gas out of each well.

Q. That's right.

A. The drop would probably be more rapid ordinarily.

Q. And the buildup would be slower, too, wouldn't it?

A. Yes, I think that is true.

Q. So the net result of the whole thing is, when those areas come into production you are going to have a more

rapid pressure drop than you have in other areas where that situation does not exist. That is an *inescapible* conclusion, isn't it?

A. Well, as far as discussing that area down there, well, yes, that's all right.

Q. Wouldn't that apply to any other lean area of the field which has high pressures today?

A. Probably would.

The witness further testified (Vol. 61, pp. 8644-8648) as follows:

Q. All right, Mr. Hammer, the fact that in balancing your quadrants and to figure them out you necessarily use the inner quadrants sort of down the axis of the field as you referred to a while ago, which is admitted as the most productive area, wouldn't that have a tendency to make your reserve a little high?

A. There is a point where I can't agree with you.

Q. All right.

A. I have made a check on the famous Quadrant 2 that you mentioned in your previous questions, and if I have checked them properly, and I believe I have—

The Trial Examiner: Quadrant 2 where?

The Witness: In Moore County.

Mr. Spencer: Moore County or Potter County?

Mr. Keffer: Moore.

The Witness: Moore. Well, I can't find it, but I do recall this, that I think the record shows that you pointed out that I had used Quadrant 2, I believe.

Mr. Lange: Moore County?

The Witness: I think the record said nine times.

By Mr. Keffer:

Q. I think that's right.

A. Now, every time I used Moore 2, and not considering the quadrants in Potter County, but just the others, I use what you term the outside lean, ten times. Now, if I would use the Quadrants 1 and 2, say, in Potter County, I would have used the outside quadrants in my grouping more than

I did Quadrant 2. In other words, I would have used the leaner one more than I did the richer one.

Q. All right, now, just there, can you give any reason why you got a larger remaining reserve in Potter 1 and 2 than you have in Moore 1 and 2?

A. Well, that is because, particularly because of the lack of withdrawals. Those are future reserves only.

Q. High pressures, isn't it?

A. Yes, higher pressures.

Q. In weighting the higher pressures in there with large volumes of production up in 1 and 2 Moore County, now, isn't that the answer?

A. No, I don't think that can be interpreted that way.

Q. How would you intepret it?

A. Just as I have interpreted it in my—

Q. All right, now, you didn't apply a recovery factor to your figures. Wouldn't that have a tendency to make your figures too high?

A. Recovery factor isn't necessary when you are—there's no need of applying a recovery factor when you have already taken care of it automatically.

Q. I want to go a little further with that, Mr. Hammer. It has just been suggested that I should have asked you what outside quadrant did you use ten times. I believe you made that statement.

A. I didn't say I used any particular one, but I said I used outside ones, not necessarily the same one, but outside ones, what I think you considered and have mentioned as lean quadrants.

Q. Well, you used, then—it is all right, just so the record is clear—you used no particular outside quadrant, then, ten times that you know of?

A. I wouldn't want to say that I have without checking that.

Q. I don't see how you could, hardly.

A. But it doesn't make any difference whether I used a particular one or not if every time you used one of your what you term a rich one, you also used a lean one. It wouldn't make any difference whether it was the same one or not.

Q. All right. I don't mean to say I agree with you on that, but again I am letting the record speak for itself.

A. All right.

Q. So we can hurry on.

Now, on this recovery factor that we touched on just a moment ago, you said you didn't have to apply a recovery factor where you have an abandonment pressure.

A. As high as 25 pounds.

Q. And yet in your own written statement you have stated that 25 pounds at the face of the well, you are going to have considerably more pounds out away from the well, didn't you?

A. Yes, that is true.

Q. So in producing to 25 pounds at the well, you are going to have a lot more gas left in the reservoir than what that 25 pounds straight across would indicate, wouldn't you?

A. The estimate as set up here is an estimate of recoverable reserves to 25 pounds abandonment.

Q. Down to 25 pounds?

A. Well head gauge.

The witness further stated on redirect examination (Vol. 61, pp. 8653-8654) as follows:

Q. You remember that last little container problem that Mr. Keffer brought up, do you not?

A. Yes.

Q. I believe you stated time and time again that those little container problems that applied to your estimates here, it was ridiculous to make the application with them?

A. That is my judgment on it, that is right.

Q. Can you state in just a few words, not going into detail, just exactly and finally what that is?

A. Actually, by utilizing ten-pound isobars and using every effort possible to balance out and carefully weigh all of the factors affecting a given quadrant, every time we utilized a group of them it had the effect of reducing any infinity of these tanks to one tank, so that ultimately it came down to the problem of being comparable to a one-tank problem. It then simply became a problem of gas out as against the pressure drop. Every time we moved from one to the other to determine one group, or, rather, to determine the reserves for one quadrant in a group, it was equivalent to setting up a new one-tank problem. By the process of elimi-

nation we automatically carried out tanks step by step across the field and every time we worked out a problem we had a one-tank problem and it was just as though in applying the production per acre pound factor, you had taken a small part of a large tank and applied that to the weighted pressure for the quadrant in question. That is the whole thing and that is all there is to it.

The witness further stated that when lean areas come into production the pressure drop will be more rapid than in the case of areas of higher productivity.

The witness then gave the production figures on Wheeler County Quadrant 1 which had been requested, and which were 523,042 Mcf. for the four years ending Aug. 1939 (p. 8628). The production figures, acreage and acre pound factor of this quadrant are shown by Commission Exhibit 191, which is as follows:

This is the best this can be photographed because it is very tightly bound.

The production for each yearly period may be determined from the above Exhibit. The total acreage in the quadrant is 23,576, and the acre pound value for the quadrant is 30.24.

The witness was excused.

Some three days later the witness was again placed on the stand by Commission Counsel and gave some further testimony with respect to the question of reserves, and over the objection of counsel for Canadian River, the following proceedings were had (Vol. 64, pp. 9187-9188):

"Q. (Mr. March Commission Counsel) Mr. Hammer, does your Exhibit 180 show in your opinion the remaining recoverable reserves of the Canadian River acreage?

A. I think so. That is what I intended. As a matter of fact, I think the record will show that Mr. Keffer asked me on cross examination the other day if I considered a recovery factor and at that time I said I considered that by choosing an abandonment pressure that that abandonment pressure automatically took care of recovery factors and I hadn't used one.

Q. I understand your estimate of reserves is not only the remaining reserves that the Canadian River has under its acreage but likewise reserves which could be recovered?

A. That was the intent of the entire thing, the recovery to 25 pounds.

Q. I would like to ask you the same question in regard to your exhibit which shows the estimate for reserves in the field as a whole.

A. That would apply the same."

Thereafter the witness HAMMER identified his Exhibit No. 294, entitled "Basic Data on Quadrants in which Canadian

River Gas Company Leases are Situated," and Exhibit No. 295, entitled, "Production Data, Hartley, Moore, Potter, Hutchinson and Carson Counties, Texas," which exhibits were subsequently admitted in evidence.

Exhibit 294 contains all of the wells in Canadian River Gas Company quadrants up to August 1, 1939. Exhibit 295 contains a breakdown by years of the production data which is recorded in previous exhibits.

The witness testified with respect to Exhibits Nos. 294 and 295 (Vol. 101, pp. 15567-15591) as follows:

* Well head gauge closed in pressures from Texas Railroad Commission official records.
* Well potentials (open flow) from Texas Railroad Commission official records.
Note: All volumes of gas in MCF. Prior to August 1, 1935 pressure base unknown. Subsequent to August 1, 1935 all gas on a pressure base of 14.65 lbs. per sq. in. absolute.

1936 marked (1) First pressure and potential
1937 " (2) " " " "

Exhibit No. 294

Well head gauge closed in pressures from Texas Railroad Commission official records.
Well potentials (open flow) from Texas Railroad Commission official records.
All volumes of gas in MCF. Prior to August 1, 1935 pressure base unknown. Subsequent to August 1, 1935 all gas on a pressure base of 14.65 lbs. per sq. in. absolute.

1936 marked (1) First pressure and potential.

Well head gauge closed in pressures from Texas Railroad Commission official records.
Well potentials (open flow) from Texas Railroad Commission official records.
Wells probably have been transferred to some other company - do not have any record; therefore, cannot identify well in Texas Railroad Commission report.

All volumes of gas in MCF. Prior to August 1, 1935, pressure base unknown. Subsequent to August 1, 1935, all gas on a pressure base of 14.65 lbs. per sq. in. absolute.

marked (1) First pressure and potential.

ase unknown. Subsequent to August 1, 1935

1936 marked (1) First pressure and potential.
1937 " (2) " " " "
1938 " (3) " " " "

He explained Exhibit 294 as follows:

Going from left to right by columns, the first column gives the name of the Company, well name and the number, and the year of first withdrawals. It must be remembered, however, that these data and schedules are all based upon the period from August to August, rather than by calendar years. Column 4 shows the total gas metered from the beginning of production to August 1, 1939. Column 5 shows the total gas metered from August 1, 1935 to August 1, 1939. Column 6 shows the gas metered prior to August 1, 1935. Column 7 shows the section upon which the well is located. Column 8 shows the block number, and Column 9, the survey. Columns 10 to 15, inclusive, represent the pressures of the various wells listed from 1935 to 1940, inclusive. Column 16 shows the well potentials as of 1935. Column 17 shows the well potentials as of 1939. Statement 1 in the footnotes to the Exhibit refers to the first pressures and potentials that were recorded in 1935 and 1936. Statement 2 of the footnote refers to the potentials and pressures first recorded in 1937. Statement 3 in the footnote refers to the first pressures and potentials recorded in 1938. The pressure base was unknown prior to August 1, 1935, but subsequent to August 1, 1935, the volume of gas is shown on a pressure base of 14.65 lbs. per square inch absolute.

The witness then testified further with respect to Exhibit 294, as follows:

"Q. (Mr. March) I notice there is another footnote at the bottom. What is the significance of that?

"A. (Hammer) Well, the significance of that is this: I had no definite information and could secure no definite information on the pressure base prior to August 1, 1935 and that footnote was put in there to segregate the 1935-1939 data from that prior to 1935.

"Q. I believe you have heretofore made explanation in regard to that data prior to 1935, have you not?

"A. I have.

"Q. As I understand it, this exhibit contains all of the wells in the Canadian River Gas Company's quadrants?

"A. To the best of my knowledge and belief, it contains all of them, that is right. Those are all of the

wells upon which I could secure data up to August 1, 1939.

"Q. All of the gas wells?

"A. Yes.

"Q. Do you make any inspection (construction), interpretation or argument in regard to the significance of any of this data?

"A. No. None whatsoever. * * *" (P. 15569).

Hammer again testified as follows:

"Q. Mr. Hammer, do you make any constructions, interpretations or arguments as to the significance of the data contained in Exhibit number 295?

"A. None whatsoever." (P. 15572).

On Tuesday, March 21, Counsel for Canadian requested that cross examination be deferred on the exhibits until the recessed hearing in Washington. Mr. Marsh, Commission counsel, objected to this, his objection (Vol. 101, pp. 15574-15582) being as follows:

Mr. March: Now, Mr. Examiner, I would like to state for the record before cross examination of the witness by Mr. Keffer that I discussed the matter with Mr. Spencer, having given him the exhibit last Saturday. Arrangements between counsel was the cross examination would be had and the Examiner would act upon the exhibit with the understanding that after it is cross examined upon that a motion to strike would be in order.

In other words, if there are any errors contained therein, it can be brought to the attention of the Examiner.

The Trial Examiner: You mean by that, Mr. March, errors in calculations, for example?

Mr. March: There are no calculations there. In other words, the company will have a complete opportunity to check it to see if there are any errors in it. We don't think there will be but there may be.

The Trial Examiner: It just isn't clear to me, Mr. March, as to what you intend to do here.

Mr. March: This exhibit was handed to Mr. Spencer Saturday. The arrangement was for cross examination to be had upon this exhibit and if the Examiner admits it into

evidence, the motion will be reserved—there will be a reservation made to make a motion to strike when this has been thoroughly checked by counsel.

Mr. Keffer: I am wondering, Mr. March, if we wouldn't arrive at the same conclusion, if ruling is just suspended on it until later.

Mr. March: We object to that. That is not the arrangement at all.

Mr. Keffer: Please let me finish, Mr. March, and then you can talk all you want to.

I understand in substance that the agreement was made between Mr. Spencer and Mr. March, as Mr. March has just stated, and I am not going back on any agreement. What I am getting to is the cross examination of this witness. I didn't understand that that was a part of the agreement. I don't know that it will even be necessary after this exhibit is checked, but, obviously, you can see by looking at either one of the exhibits that it will take almost as long to check it as it took Mr. Hammer to make it, because you have to go back and check every one of those wells. It is going to be a tremendous job. That checking may develop some matters we want to cross examine upon. I don't know that it will. The exhibits have been marked and they are in the record. If we can have until the next session to check it over, we believe it would facilitate things. We could do that, making some sort of a check on it, and then we could cross examine upon it then. It wouldn't embarrass or delay you any. In other words, in that manner you can accomplish the same thing.

Mr. March: We object to the withholding of the cross examination of this geologist until we get to Washington. This is the same type of exhibit as 259 was. I cross examined upon that without any delay. There were a bunch of wells, two or three hundred listed thereon. They obtained these exhibits Saturday and there is no reason we can't have the cross-examination upon them now. If we wait until we get to Washington, it may be reopened again. My arrangement with Mr. Spencer was, as I stated, clearly understood. There is a simple cross examination that should be had upon

it now. If there are any errors in here, a motion will be in order to strike if it is admitted in evidence. Commission's counsel absolutely takes exception to any dilatory delay in the cross examination. There is no reason for it.

Mr. Keffer: There is nothing dilatory about it, Mr. March, as I am trying to expedite the matter.

Mr. March: It is coming to the matter of a stall when another arrangement was made.

Mr. Keffer: Mr. March, there is no basis for that statement.

Mr. March: This is basic data. Mr. Peterson prepared an exhibit of gas produced by the field. I subsequently found that I forgot to ask him for the working papers that he used. I cross examined Mr. Peterson and I didn't hesitate about doing it, either. Our witness is not making any construction of the data. The interpretation there *speak* for itself.

The Trial Examiner: Well, I think perhaps, Mr. Keffer, if you have any questions of Mr. Hammer as to the foundation for the exhibit, you might proceed in that manner at this time. Then, as I understand it, if upon checking the data it is shown that an error has occurred, the error may be either corrected or stricken from the record. Is that the situation, Mr. March?

Mr. March: Or the correct figures may be given by Mr. Keffer.

Mr. Keffer: That is perfectly all right, Mr. Examiner, but my only thought was this: I didn't hear the agreement between Mr. Spencer and Mr. March, but as I understood it, as Mr. Spencer detailed it to me, there was to be no cross examination at this time.

Mr. March: Mr. Spencer has specifically stated that the Examiner would rule upon the thing and it was predicated upon a motion to strike. As a matter of fact, the only cross examination that would be appropriate would be where he got the information and data.

Mr. Keffer: I don't know that it will be, Mr. March.

Mr. March: That is an old thing, to delay this proceeding. The time has come that Mr. Keffer might cross examine here for a change. He has had since Saturday to look over this and if there are any errors, as I discussed it with Mr. Spencer, if any errors develop, they may be brought to the attention of the Examiner in Washington and a motion lodged to strike if the Examiner admits the exhibits in evidence. It is perfectly in order, and for Mr. Keffer to try to keep this geology open and hold up the cross examination of one of our witnesses, Mr. Hammer, we most vigorously except and we urge that Mr. Keffer proceed with the cross examination. That was not my agreement with Mr. Spencer.

Mr. Keffer: My only point is this: I can't tell whether there would be any cross examination upon this or not but I think it is obvious to anyone looking at those two exhibits, to have checked them since Saturday—that is preposterous. I think Mr. Hammer will agree with me on that. My only thought is, I certainly wouldn't want to waive the right to cross examine. Everything else is perfectly satisfactory to me. There may not be any cross examination on this exhibit or these exhibits, but I can't tell as I haven't the slightest thought on the matter at this time.

The Trial Examiner: Well, Mr. Keffer, supposing if you have any questions as to the foundation, you ask those now and the Examiner will then act upon the offer of Commission's counsel, and the reservation that has been made may serve to eliminate any possibility of inclusion of errors in these particular exhibits. It seems to me on that basis there is really not much harm that could come from the exhibits themselves.

Mr. Keffer: I appreciate that. As I stated a moment ago, my only thought was, as we do get into checking these items it may develop from the Examiner's standpoint, as well as our own, to have some cross examination upon those things. The chances are there will be none. In fact, I can't see right now that there will be, but there might be, and it is a matter that I haven't explored yet.

Mr. March: As the Examiner can see, it is just like the other exhibits put in by counsel for the companies. It is just statistical data. In fact, some of the basis statistic data

was used in the estimate of reserves subsequent to 1935. There is no construction being made of this. The only type of cross examination there could be on exhibits of this nature would be as to the source of information and where he got the data. If there were errors made, there could be motions made to strike. To leave that open until we get to Washington and reserve Mr. Keffer the right to cross examine there, this thing might go on for weeks.

"What do you know about that well, Mr. Hammer? What is your construction of that well there, Mr. Hammer?"

Mr. Hammer hasn't made any construction of the exhibits. The figures speak for themselves, and there is no reason in the world why Mr. Keffer, as able a lawyer as he is, knowing about these wells and living in that vicinity, can't proceed with the cross examination here when I cross examined upon the other exhibits right off the bat.

Mr. Keffer: I'm not as smart as you are, Mr. March, and I can't do it that way.

I am going to cross examine, Mr. Examiner, reserving the right by reason of the matters stated here in open court, for future cross examination if an inspection and test of the exhibits would lead me to believe that further cross examination would be necessary or desirable.

Mr. March: We object to that. He can cross examine now and make his motion to strike in Washington if there appears to be errors in the exhibits.

Mr. Keffer: I don't see how we can make a motion to strike under the circumstances. Mr. Hammer has one set of figures here and should we say there should be something else and we should strike Mr. Hammer's figures?

Mr. March: You had six months to bring in the data on the wells. Why didn't you bring that data in here?

The Trial Examiner: I think we are spending considerable time on a matter that can be worked out to the satisfaction of all concerned. I don't think, Mr. Keffer, the Examiner is going to take any step that might jeopardize your rights in the proceeding. On that assumption, as I have stated, I think if you have any questions as to the founda-

tion, you may ask them and we will act upon the exhibit now and we will cross the next bridge when we come to it.

Mr. Keffer: All right.

Cross Examination

By Mr. Keffer:

Q. Now, Mr. Hammer, I note that you show production prior to August 1, 1935. When you were speaking about it a while ago, you were speaking a little low and I didn't quite hear you. You might have stated how you got that, but I didn't catch it.

A. All of the data on all of these sheets are data that were taken from the records of the Texas Railroad Commission.

Q. Well, take wells over in the Sanford area, for example, and perhaps some other wells which you have included on this statement where production records were not complete prior to August 1, 1935. How did you handle that?

A. The only thing is, these represent the records of the Texas Railroad Commission. If there were wells where the records weren't complete, naturally this doesn't show it.

Q. Did you find any that were not complete?

A. That would be a hard thing to answer on all of the wells there.

Q. But you spent quite a little time gathering this data and I wonder what you found in that respect.

A. I couldn't go back and give you definite information on wells and I don't intend to do that.

Q. I haven't asked you to do it. I am just asking what you found in that respect.

A. Unquestionably there are some wells upon which the data are not complete and I know that. I lay no particular stress at all on this data prior to 1935.

Q. The upshot of it is that you will acknowledge on your production records, at least, that your data is incomplete?

The Trial Examiner: Prior to 1935?

Mr. Keffer: August 1, 1935.

The Witness: Yes, there is that possibility.

By Mr. Keffer:

Q. Not only a possibility but a probability?
A. That is right.

Hammer again testified with respect to the production data as follows:

"Q. You did have complete production figures?

"A. I didn't have, no, and I have so stated to you.

"Q. Did you mean to say here that your production figures back of 1935 have no relevancy?

"A. Nothing particularly—no particular relevancy as far as these exhibits are concerned." (P. 15588).

Mr. Hammer again testified:

"Q. Mr. Hammer, I take it you yourself wouldn't want to rely upon those figures?

"A. Prior to 1935?

"Q. Prior to 1935.

"A. Well, I didn't." (P. 15589).

Mr. Hammer again testified on redirect examination (Vol. 101, pp. 15590-15591) as follows:

By Mr. March:

Q. Mr. Hammer, you did make an effort, did you not, to get reliable data prior to 1935?

A. I made every effort possible.

Q. You were unsuccessful?

A. That is right.

Q. You believe that the data which you got prior to 1935 is the best data that can possibly be gotten in regard to metered gas?

A. Yes, I do.

Q. Mr. Hammer, there have been some questions here raised as to the fact that you leave off certain pressures. As a matter of fact, the only thing you vouch for here is the figures you have recorded here?

A. That is right.

Q. In other words, if it should happen there are some pressures which are recorded by the Railroad Commission which you do not have, it would be merely an oversight on your part and you are merely testifying to the figures which you have here in the exhibit?

A. That is right. Where certain data isn't contained here, it is simply a case of where the records of the Texas Railroad Commission showed no data for those periods.

Mr. March: That is all.

Mr. Keffer: That is all.

The Trial Examiner: You may step down, Mr. Hammer.

(Witness excused.)

Mr. March: I move for the admission of the exhibits, Mr. Examiner—I think the relevancy is obvious of Exhibits 294 and 295—with the understanding that the motion to strike will be in order when we reconvene in Washington, as agreed by Commission's counsel and Mr. Spencer.

Mr. Keffer: I have no objection, Your Honor, to the admission of the exhibits as such, except as to the stock objection as to the relevancy and materiality, but with the reservation to cross examine further concerning them if upon further check it is deemed desirable.

Cotner and Crum Report

Commission Counsel introduced into evidence an article entitled, "Geology and Occurrence of Natural Gas in Amarillo District, Texas," by Victor Cotner and H. E. Crum in collaboration with other geologists, and which article was published in August, 1933, in Volume 17, Number 8, of the Bulletin of the American Association of Petroleum Geologists. This article has been designated as Exhibit 215. Said publication, in so far as pertinent in this proceeding, is as follows:

Volume 17 Number 8

Bulletin of the American Association
of Petroleum Geologists
August 1933

Geology and Occurrence of Natural Gas in Amarillo District, Texas*

Victor Cotner** and H. E. Crum***
Amarillo, Texas, and Charleston, West Virginia

Abstract

Natural gas is found throughout an almost continuous belt extending from central Beckham County, Oklahoma, northwestward to northern Moore County, Texas, and thence northward to and including Morton and Stevens counties, Kansas. This belt of productive gas territory is more than 200 miles in length and ranges from 5 miles to 40 miles in width and embraces an area of proved and semi-proved gas territory of more than 2 million acres, one of the largest and most important gas areas in the world. Gas is produced from beds of Permian and Pennsylvania age. Accumulation of gas is closely associated with deposition and folding of these beds in relation to a buried mountain range known as the Amarillo Mountains. Natural gas has been known to exist in this area since 1918. From that time it has developed in economic importance until today it occupies first place in production of natural gasoline and carbon black and is rapidly becoming the largest producer of natural gas for domestic and industrial use. Natural gas is now being transported from this district by pipe lines to such distant points as Chicago, Indianapolis, Denver, and Fort Worth. The writers discuss the geologic occurrence of the gas and set forth production data in connection with its utilization.

*Presented before the Association at the Oklahoma City meeting March 24, 1932. Manuscript received, March 10, 1932. Reprinted from Geology of Natural Gas, a special symposium on world occurrence and geology of natural gas which will include authoritative papers on the gas fields of North America, Europe, and Asia. Geology of Natural Gas, now in manuscript form, will contain more than a thousand pages.

**Columbian Carbon Company.
***Idem.

Acknowledgment

The following geologists have contributed material or criticism in the preparation of this paper, to all of whom the writers express their appreciation: L. M. Oles of the Prairie Oil and Gas Company; J. D. Thompson, Jr., consulting geologist; W. E. Hubbard of the Humble Oil and Refining Company; T. F. Newman of the Skelly Oil Company; Frank T. Clark of the Empire Gas and Fuel Company; and Richard W. Camp of the Consolidated Gas Utilities Company.

Introduction

The Amarillo district embraces the Hugoton district of southwestern Kansas, the Oklahoma Panhandle, the Texas Panhandle, and the Sayre district of southwestern Oklahoma. This area, with the exception of the Sayre district, lies in the High Plains Province. The Sayre district lies just below the rim rock which borders the High Plains Province on the east. The High Plains Province is an almost treeless plain covered with alluvial deposits except along the larger streams where erosion has cut deep canyons in which the underlying Triassic and Permian strata are exposed.

Production of gas in this district is closely associated with a system of buried mountains or granite ridges extending northwestward from the Wichita Mountains of Oklahoma. The sedimentary formations which overlie these buried mountains have been folded into an arch over the granite core and form an immense anticlinal fold into which the gas and oil have migrated and accumulated. From the crest of the anticlinal fold the beds dip away northeastward into the Anadarko basin, southwestward into the West Texas Permian basin, and westward in the Dalhart basin. Separate domes and basins occur within the area, but these features are probably related to the principal mountain system. On the northwest insufficient drilling has been done to define clearly the limits of the district. Figures 1 and 2 set forth these relationships.

Economic History

Gas in this district was discovered in northern Potter County, Texas, in December, 1918. This discovery was on a surface anticlinal fold surveyed by Charles N. Gould, geologist, and called the John Ray dome. Drilling of the

discovery well was recommended by Gould, and gas was encountered at a depth of 2,605 feet. The first commercial well in the Sayre district, Beckham County, Oklahoma, was completed in July, 1922, gas being encountered at a depth of 2,755 feet. Gas was discovered in Seward County, Kansas, in December, 1922, but not until May, 1927, when the first gas well of Stevens County was brought in by the Independent Oil and Gas Company at a depth of 2,617 feet, did this district become important. In 1925 and 1926 several gas wells were completed in Texas County, Oklahoma. All of the discovery wells were similar in that they started at or close to the same geologic horizon, penetrated similar strata, and encountered the first showings of gas in the dolomite series of Permian age. This similarity was readily noted at the time but that these wells had roughly defined the extent of the immense gas field which we know today was not recognized until long afterward. They were considered to have opened separate and local fields.

The discoveries of gas in this district were made during the search for oil, and the finding of gas was not hailed with enthusiasm. The search for oil continued with the result that the proved gas areas have expanded to their present known limits. Only since trunk lines have been laid to distant markets has an effort been made to develop the gas reserves. Immense volumes of gas were encountered in wells which succeeded in producing oil. In the early development of the oil fields, little effort was made to conserve this gas and the wastage was enormous. Later the operators adopted conservation methods of drilling through the gas strata with less wastage of gas.

There are now eight counties in the Texas Panhandle from which gas is being marketed, while in four others gas has been found in commercial quantities. Gas has been found in two counties in the Oklahoma Panhandle, one of which is marketing its product. The Sayre district, in Beckham County, Oklahoma, has been marketing gas in limited quantities since 1923. The Hugoton district, in southwestern Kansas, has many shut-in gas wells which are being connected to trunk lines. Lines are now carrying gas from the Amarillo district to such distant markets as Chicago, Des Moines, Indianapolis, Denver, Midland, Wichita

Falls, Enid, and Kansas City. This marketing development has taken place principally during the past four years. Lines under construction will soon extend the markets to include St. Paul and Minneapolis.

Geology Pertaining to Occurrence of Natural Gas

Regional Stratigraphy

Table I shows a correlation of geologic formations which are found in the Amarillo district and the neighboring districts. Gas occurs in the lowest formations of the Permian and the highest formations of the Pennsylvanian, these beds having been deposited in and along the southwest flank of the Anadarko basin and the north flank of the West Texas Permian basin. The Granite wash and the "Gray lime," both of Pennsylvanian age, show definite evidence of shoreline deposition. Along the flanks of the buried mountain range, there is a progressive overlap of formations against the granite core (Fig. 2). The "Gray lime" is confined, except in the low gaps, to the flanks of the ridge, while the dolomite and anhydrite series, both of Permian age, were deposited over the mountain ridges. There are two known possible exceptions where the granite peaks are found in contact with the "Red Cave" and even in these localities there is evidence that the dolomite and anhydrite have been removed subsequent to deposition. There is an unconformity at the top of the anhydrite and possibly an unconformity at the top of the "Gray lime."

Producing Horizons

The producing horizons of this district are the dolomite series of Permian age, the "Gray lime" of Pennsylvanian age, and the granite wash of Pennsylvanian age. Figure 2 shows cross sections of the gas-producing counties. These sections are built up from wells logs and sample data and show the structural attitude of the producing horizons, erosional and depositional features and their relation to the granite ridge.

The most widespread gas-producing horizon is the dolomite series, which is productive in the higher portions of the

Amarillo arch and northward across the Oklahoma Panhandle and into the Hugoton district of Kansas. This horizon consists of buff to white crystalline dolomite interbedded with gray shale. The dolomite has an colitic phase throughout the Texas Panhandle, though in the Hugoton district sands appear locally at this horizon in this series.

The "Gray lime" is less widespread, being absent in the upper parts of the Amarillo arch, in the eastern counties of the Texas Panhandle, and in the Sayre district. In the western and northern counties of the Texas Panhandle this horizon is the source of the largest gas wells. Close against the Granite ridge it contains lentils of granite wash and in other localities it shows evidence of local fracturing, faulting, and solution cavities which when encountered yield the larger wells.

The Granite wash lies immediately over the granite mass except toward the basins, where it has been found to overlie beds of probable Mississippian or Ordovician age. Granite wash is the resulting material derived from disintegration of the granite mass following mountain-building movement. The granite gravels have been washed out from the main granite mass and have accumulated in the valleys and depressions and as alluvial deposits along the lower flanks of the mountain range. Local deposits of granite wash are found high on the granite slopes. Granite wash production is confined to the Texas Panhandle.

Gas wells have been found locally in fractures and the weathered surfaces of the granite core, the most notable being in Gray County, Texas.

Structural History

It is agreed by those who have studied the Wichita Mountains of Oklahoma and the Texas Panhandle that uplifting of this mountain system has occurred at several periods since the first movement in early Pennsylvanian time.

The uplift in the early Pennsylvanian was followed by partial erosion of pre-Pennsylvanian sediments from the uplifted portion. A barrier was formed separating the Anadarko and West Texas basins. Deposition in these basins continued until, in the later Pennsylvanian, another uplift

occurred along the mountain chain. Erosion following this movement completely denuded the granite ridge of Pennsylvanian and older sediments and the granite core itself was attacked by the forces of weathering and erosion. Oscillating shore-line conditions were brought into existence along the mountain front, and sands and arkoses from the granite ridge were being carried outward and intermingled with the shales and limestones being deposited in the basins. Arkosic limestones, shales, and dolomites are characteristic of the late Pennsylvanian sediments (Cisco-Wabaunee) close to the Amariflo Mountains.

Interfingering of arkosic material with basin sediments continued during the subsequent deposition of Permian dolomite and anhydrite until the granite peaks were entirely covered. By this time all but the very highest peaks on the ridge had been covered by dolomite.

Following the deposition of anhydrite which marked the close of the "Big lime" time another upward movement of less magnitude occurred which was accompanied by faulting and folding of the sediments. Subsequent erosion removed the anhydrite and dolomite from the highest peaks and removed part of the anhydrite from less lofty parts of the buried mountain chain. This erosion is testified by finding pieces of anhydrite and dolomite embedded in the lower part of the "Red Cave" section near and on the highest peaks. The cross sections of Figure 2 show that faulting occurred following "Big lime" time. Increase of the throw of those faults with depth indicates that this faulting occurred in the granite basement rocks during earlier movements and that the later faulting had occurred along the old lines of weakness.

The arching of Permian and Triassic beds into the anticlinal fold which is superimposed above the Amarillo Mountains has been brought about largely through subsidence of the basins and compaction of the basin sediments. Lesser movements along old lines of weakness are also indicated as having taken place during and following the deposition of these younger beds.

Structure

The structure of the sedimentary rocks which contain gas and oil in the Amarillo district consists of a broad arching of these beds over the buried Amarillo Mountains. Local structure is influenced by irregularities of the mountain range such as peaks, gaps, valleys, and fault scarps. The overlying sedimentary beds have been warped to conform with these irregularities upon which they have been deposited. The arching of the beds has been accentuated by successive uplifting of the mountains and by settling of the basins. Some minor folding along the flanks of the main uplift may be due to lateral pressures induced by the uplift of the ridge or by faulting at these periods. Figure 1 shows the regional structure of the district based on elevations on the top of the anhydrite series ("Panhandle Big lime"). Figure 2 shows cross sections of the various gas-producing counties.

It is a coincidence in the Amarillo district that the water level in each porous horizon occurs at or close to sea-level. Above the water level a band or zone of oil occurs and the upper portions of the anticlinal fold contain gas only. With this simple structural arrangement of the water, gas, and oil it is necessary only that the porous horizon lie above sea-level at the site of the test well in order to secure gas or oil production. The amount of production obtained in the proved area depends solely on the local porosity. Perhaps nowhere in the world is there an area of comparable magnitude in which oil or gas operators may proceed with their development with such assurance of obtaining the desired result. In the oil- and gas-producing counties of the Texas Panhandle, the ratio of dry holes to producing wells is 1:15; for the entire district, the ratio is 1:11. In the defined gas areas, the number of dry holes is practically negligible.

Along the general course of the main Amarillo anticline there are several local domes. The discovery well of the district was drilled on the John Ray dome in Potter County. The first oil well of the district was drilled on the flank of the 6666 dome in Carson County. The LeFors dome in Gray County is noted for its large gas wells, as is likewise the Lela dome in Wheeler County. Other domes which are

closely associated with the main uplift are the Bush dome, in Potter County, which is noted for its helium gas production, and the Sayre dome in Beckham County. The last named domes are separated from the main uplift by faults as shown by the cross sections. The Bravo dome, in Oldham County, has been tested by drilling and found to be nonproductive of oil or gas. The "Big lime" is entirely missing, the "Red Cave" resting on the Granite wash. It is an accepted belief that the Bravo dome was a land mass during "Big lime" time. Minor folds and flexures occur along the flanks of the main uplift, notably in southwestern Hutchinson County and eastern Moore County.

In the northern Texas Panhandle, the Oklahoma Panhandle, and the Hugoton district of Kansas no anticlinal folding is known to exist which is comparable in area or in structural relief with those here described. In these areas the structure appears to be monoclinal with the gas accumulating up-dip in porous dolomite or sandstones which lens out up the dip westward. However, further development of these areas and the drilling of magnetic "highs" may yet demonstrate some anticlinal folding.

In determining the location of buried granite ridges in this district the magnetometer has proved very accurate and, because of the close association of gas and oil occurrence with these granite ridges, this instrument has demonstrated its commercial value. Magnetometer surveys in the Amarillo district have not only delineated granite ridges, but they have also indicated the location of faults. The northern portion of the district has been mapped in great detail by the magnetometer, but insufficient drilling has been done to demonstrate whether the "highs" which have been found reflect the presence of similar granite ridges. South of the Amarillo Mountains several test wells have been drilled on magnetic "highs," but the drill failed to show other than normal conditions. Whether other influences than the granite basement were affecting the instrument or whether the interpretation of the readings in these early surveys was at fault is not known.

Reservoir Rocks

The reservoir rocks of the gas and oil fields of this dis-

trict consist of dolomite, limestone, sandstone, and arkose (granite wash). The dolomite is white to buff crystalline or colitic. It occurs as a blanket formation over almost the entire district, retaining an average thickness of 250 feet. In a driller's log the first recorded showing of gas generally marks the top of this formation. Because of the variability in thickness of the overlying anhydrite series, geologists are noting carefully this datum point for constructing contour maps. The largest production comes from the colitic zones. As shown by the cross section in Figure 2, the dolomite thickens basinward. The limestone is referred to locally as the "Gray lime." It lies next below the dolomite series in the geologic section. It does not produce oil or gas east of central Gray County, Texas. Production from the "Gray lime" is due to the presence of dolomitic and arkosic phases and to the occurrence of fractures. In Moore County this formation accounts for the oil production and for most of the gas production. This formation likewise thickens rapidly basinward.

The arkose in this district is known as Granite wash. It varies in character from fine granite sand to large granite boulders. Where most productive of gas and oil, it consists of coarse arkosic sand and gravel. Its porosity is highly variable along the flanks of the anticline, due to its being impregnated locally with red shales or lime cementing materials. Where no red shales or cementing materials are present, this formation is the most highly productive in the entire district. The gas of the eastern Texas Panhandle comes almost entirely from the Granite wash, because throughout most of this area the dolomite and "Gray lime" are missing at the gas-producing datum levels. The Granite wash is also important as a gas producer in northern Potter County. It is known to exceed a thickness of 700 feet locally.

Closely related to the arkose horizon, and difficult to distinguish from it, is the zone of weathered and fractured granite in place. A study of the granite surface at the outcrop in the Wichita Mountains of Oklahoma shows that

weathering has produced a large number of fractures and joints in the granite and also that leaching out of the ferromagnesian minerals has left cavities in the granite which are an ideal reservoir for gas and oil accumulation. Large wells have been encountered in this zone, notably in Gray and Wheeler counties.

A striking feature of the producing horizons is their remarkable continuity. The dolomite is practically continuous and its porosity is notably uniform throughout the area. The "Gray lime", although not present except locally over the ridges, produces gas or oil in a continuous band 60 miles in length. The Granite wash, although present only locally on the ridges, produces gas or oil in a continuous band for a distance of more than 70 miles.

Reservoir Cap Rocks

The reservoir cap rocks of the Amarillo district may be classified as primary. Gas or oil is found in the dolomite when the drill has penetrated through the impervious anhydrite series. In the "Gray lime" producing horizon, the gas is found usually beneath a bed of shale or dense limestone which constitutes the cap rock. As a general rule, the upper part of the Granite wash contains beds of red shale and it is only after the drill has passed through these red shales that oil or gas is encountered. It would seem, therefore, that the cap rock beneath which oil or gas is found in this district is in its original state and has not been altered to its present impervious condition.

Oil

In this district oil occurs within the same reservoirs as the gas and water, there being no classification of "oil sands," "gas sands," and "water sands."

To date no oil has been encountered in the Hugoton district, and the Oklahoma Panhandle has had but one showing of oil, while the Sayre district had two or three commercial wells during its early life. The Panhandle of Texas

has been a major oil-producing district since the fall of 1925. The oil is produced from twenty-seven localities or so-called "pools" distributed throughout a narrow band 90 miles in length and lying along the north flank of the Amarillo arch. One minor discovery of oil has been made on the south side of the arch in Carson County in close proximity to a probable fault. No oil has been found to date on the Bush dome in Potter County, but this is not conclusive evidence that oil will not yet be found on this fold. The encountering of a small quantity of oil in the dolomite close to the Potter County fault indicates that oil may yet be expected whenever further development is carried on.

Migration of Oil and Gas

From the fact that the Anadarko basin contains carbonaceous formations in the Pennsylvanian and in the older Paleozoic rocks, though neither the presence nor absence of such beds has been demonstrated in the West Texas Permian basin adjoining the Amarillo Mountains, it is assumed that the gas and oil have migrated into the anticlinal folds from the Anadarko basin. The further fact that all of the important oil fields of the Texas Panhandle lie on the flank of the arch toward the Anadarko basin supports this view. The reservoir rocks are of late Pennsylvanian and early Permian age and the principal uplifting and folding of these beds has occurred at various times since early Pennsylvanian. Considering the origin of the reservoir rocks, it seems plausible to assume that the accumulating gas has displaced water within the reservoirs.

* * * * * *

Volume

Many wells capable of producing large quantities of gas have been drilled through the gas to the oil "pay." In the following tabulation, only wells completed as gas wells are listed. Wells have not been segregated as to the different zones from which they may be producing. Initial open flows of gas wells vary from two million cubic feet in a few small wells to wells in excess of 100 million. The production is dependent upon local porosity. Wells near to each other may vary considerably in open flow volume, but their rock pressures are the same. Certain areas develop large open

flows, but almost in the center of such areas very small wells may be encountered, which is due either to a granite peak cutting out the porous zones or red shale cementing the Granite wash or the dolomite zone being less porous. The 703 gas wells of the Panhandle district show an average open flow of 26.8 million cubic feet per day.

Table II

Annual Completions, Texas Panhandle

Total	414,180,047	2,064,285,155	592,940,000	135,000,000	233,200,000

Total estimated withdraws from field 3,439,405,202 thousand cubic feet.

During 1931 there were 69 gas wells completed for an average open flow of 26,262,000 cubic feet per well.

During 1932 there were 27 gas wells completed for an average open flow of 23,215,000 cubic feet per well.

Annual withdrawal figures are not available in accurate amounts. Many statements have been made as to gas flowing to waste in the Panhandle field, but, due to the large area included in the drilling operations, the figures have probably been only a rough estimate.

Table IV shows an estimate of the total gas withdrawn from the Panhandle field from its first development until January 1, 1933. The estimate presents an idea of the probable total amount of gas withdrawn from the field. Several of the items in the estimate are comparatively correct, but others are speculative and may vary considerably from the true amounts. Withdrawals by public utilities companies from 1932 show an increase over 1931 due to the completion of several major gas pipe lines during 1931. During the same period there has been a reduction in casinghead gas volume.

The producing area of the Texas Panhandle field is estimated at approximately 1,300,000 acres (Fig. 3). Of this amount, 100,000 acres has been drilled for oil production, although this has not been fully drilled up and may not all be productive of oil in paying quantities. Of the total gas area, that part on which initial volume of 10 million open flow per well or larger may be expected consists of approximately 896,500 acres. Initial volume contours of the field would show that a belt of small volumes extends around the outer edge of the producing area. Some small areas of less than 10 million volume exist within the larger open flow areas, being due to porosity factors previously mentioned.

Pressures

The rock pressure of Panhandle field is sub-normal, being less than half the normal hydrostatic head, and is uniform throughout the area, excepting the Bush dome in Potter County. The fact that pressure is equal and uniform in all productive zones indicates communication of the porous strata at the unconformity along the surface of the buried granite ridge.

The controlling pressure factor is not definitely known. The porous strata of the producing zones do not crop out at any known place in the form in which they are found in the wells. The character of the producing strata changes to shales and non-porous materials where their equivalents crop out. It is therefore assumed that at this time the producing zones are not exposed to a definite known hydrostatic head as a source of supply and that the pressure now existing was created when the producing zones were exposed to sea waters of former times. However, some geologists attribute the pressure to the hydrostatic head originating where the sedimentary rocks are in contact with the granite in the Wichita Mountains in Oklahoma at approximately 1,000 feet above sea-level.

The initial rock pressure of the Panhandle field was 430 pounds per square inch. Variations of 10 pounds have been noted on well completion records which may have been due to inaccurate gauges.

Decline in pressure is greatest throughout the areas developed for oil. This has been caused by the withdrawals of immense quantities of casinghead gas as well as gas wasted when drilling through gas strata to the oil "pay." From the developed oil fields the pressure increases rapidly into the main gas-producing areas.

The following data give some idea of the present rock pressures in the gas-producing areas. The pressures were taken in June, 1931, at gas wells only.

Most of the rock pressures in the producing oil areas are considerably lower than those given in Table V.

The Bush dome in Potter County had an original rock pressure of 723 pounds. The pressure in December, 1931, was approximately 710 pounds.

Table V

County	Maximum Pressure in Pounds	Minimum Pressure in Pounds	Number of Wells Gauged	Average Pressure in Pounds
Carson	430	300	88	353
Gray	425	245	32	355
Hartley	426	425	4	425
Hutchinson	410	155	28	363
Moore	430	374	33	420
Potter	428	400	33	418
Wheeler	430	314	86	386

Recoveries

The great variation of open flow of wells in the Texas Panhandle indicates considerable differences both in porosity and thickness of the pay strata. Porosity is the main factor. This is probably substantiated from well-log records on pay thickness. Also with the different pay horizons it can readily be seen that estimates of reserves in the field should be calculated by the pressure-decline method. With this method it will prove difficult to obtain accurate results due to the fact that the area of the field is so large that simultaneous records of the wells are difficult to obtain as to withdrawals and pressures. Many estimates have been made on recovery

per acre by engineers for the pipe-line companies, the more recent estimates ranging from 12 million to 17 million cubic feet per acre. In 1927 C. Max Bauer, assuming that the ultimate recovery would be 50 per cent, estimated the total recoverable gas in the reservoir at 4,436 billion cubic feet, but there are more data available at this time. Accordingly the Bauer estimate of total gas per acre was 9.2 million cubic feet.

As no water is present, on structure, in the gas pays or directly under them, the Panhandle field will no doubt have an ultimate recovery of all gas in the reservoir with the exception of a very small percentage.

It is now estimated that there are 896,500 acres in the Amarillo district in which wells will be completed with an average initial open flow of 10 million cubic feet or more; that the average thickness of "pay" is 65 feet; the average porosity is 20 per cent; and the initial reservoir pressure was 430 pounds per square inch. Reduced to a 2-pound base, the preceding data give an estimate of 15,289,000 cubic feet per acre, and an original reservoir content of 13,706,588.5 million cubic feet of gas.

In addition to the foregoing area, there are gas-bearing areas of smaller open-flow volumes and oil-field areas in the Amarillo district which must be considered. These areas are estimated to cover 403,500 acres. They include localities where wells are expected to produce less than 1 million cubic feet on completion. It is estimated that 6 million cubic feet of gas per acre will be recovered from these areas, giving an additional reservoir content of 2.4 trillion cubic feet, and a total original reservoir content of 16.1 trillion cubic feet or gas in the Amarillo fields.

The foregoing figures are simply an estimate and must be considered as such, but are given in order to show the tremendous amount of gas within this great reservoir.

If it is assumed that estimates of gas withdrawals in Table IV are approximately correct, there is now an approximate reserve of 12.7 trillion cubic feet of gas in the Panhandle field at this time, or about 79 per cent of the original amount.

Ultimate recovery per well will no doubt show marked variations. The following data are from a gas well in Gray County and are given as an example of recovery per well in an area where there are no near-by offsets. The records show that 4,327 million cubic feet of gas were withdrawn in a period of three years; rock pressure declined 20 per cent; and the open-flow volume declined 42 per cent. A gas well in Potter County has produced 14,840 million cubic feet of gas to date, while the pressure declined from 430 pounds to 395 pounds. A gas well in Wheeler County has produced 7,970 million cubic feet of gas to date. These wells are special cases and do not represent an average.

During 1931 the Panhandle field produced 21,137,355 barrels of oil. During 1932 it produced 18,014,920 barrels of oil making a total to December 31, 1932, of approximately 194 million barrels of oil produced from this field.

Utilization of Gas

Table VI shows that approximately 4,200 miles of major gas pipe lines have been built to take gas from the Panhandle. This does not include any lateral or branch lines. The major gas lines have an estimated daily capacity of 887 million cubic feet per day and the local lines a capacity of 80 million cubic feet per day, or a total pipe-line capacity of 967 million cubic feet per day.

There are several other smaller pipe-line companies serving local towns in the Panhandle district.

Gasoline Plants

Most of the casinghead gasoline plants are of the absorption type and are operated on direct well pressures and by compressors. On January 1, 1931, there were 50 casinghead gasoline plants in the Texas Panhandle, estimated to have a daily capacity of 1,024,500 gallons and capable of treating 1,407 million cubic feet of gas daily.* There are also 5 gas-

*Editor's Note.—According to testimony at a hearing before the Texas Railway Commission at Pampa, Texas, February 15, 1932, about 1 billion cubic feet of gas is passed through natural gasoline plants daily. About 530 million cubic feet of the residue gas is used daily for the manufacture of carbon black and sold to gas transmission lines, and approximately 470 million cubic feet of residue gas is wasted to the air or burned by flares.

Table VI

Pipe Lines Obtaining Gas From Panhandle Field

Company	Size in Inches	Length in Miles	Daily Capacity Thousand Cu. Ft.	Withdrawal for 1932 in Thousand Cu. Ft.	Terminal

U. S. Government	6		10,000	848,146	U. S. Helium Plant

oline absorption plants on natural gas lines in the district having a daily capacity of 357 million cubic feet.

Not all plants are now operated at capacity. Because of the decline of flush oil production, and proration of oil properties, the casinghead plants operated at only 4/5 of their rated capacities during 1931. Gasoline recovery plants on natural gas transmission lines operate according to gas passed through the pipe lines.

Carbon Black

The large quantities of casinghead gas being produced from the oil wells in the Texas Panhandle created a favorable condition for the manufacture of carbon black. During the early development of drilling wells the gas was blown into the air and wasted. Gasoline extraction plants were soon erected to extract the gasoline from this casinghead gas. The residue from the casinghead plants was used for fuel

Table VII

Casinghead Gasoline Plants in Texas Panhandle

County	Number of Plants	Daily Capacity in Gallons	Estimated Daily Capacity Thousand Cu. Ft. Gas

1932	226,779,672	352,887,000
Total	1,256,873,622	2,235,287,000

on the leases, but this required only a small fraction of the total. In September, 1926, the first residue gas was burned for the manufacture of carbon black. The carbon industry continued expansion during 1927, 1928, and 1929. The greatest construction program was during 1928. No new plants were built during 1931.

With the close of 1929 the production of carbon black had become equally as important, in the Texas Panhandle, as the production of oil and casinghead gasoline. At the close of 1930 there were 25 carbon plants in the Texas Panhandle with a combined daily capacity of 862,700 pounds of carbon black and capable of burning approximately 567,765,000 cubic feet of gas per day.

Carbon black plants in the Texas Panhandle comprise 58 per cent of the total capacity of all plants in the United States. In 1930 the Texas Panhandle plants produced 67.7 per cent of the total output of carbon black in the United States. About 1.5 pounds of carbon black are produced from 1,000 cubic feet of gas. Practically all of the plants are of the channel type. Only residue gas from casinghead gasoline plants is used in making carbon black.

Composition and Properties

The composition of natural gas in the Panhandle fields varies to some extent according to the reservoir and locality. Table X shows representative analyses.

Table IX

Carbon Black Plants in Texas Panhandle

Counties	Number of Plants	Daily Capacity in Pounds
Carson	2	86,800
Gray	8	301,400
Hutchinson	12	450,500
Wheeler	3	24,000
Total	25	862,700

Carbon Black Production in Texas Panhandle

Year	Pounds Made	Estimated Amount of Gas Used in Thousand Cu. Ft.
1926	2,566,000	1,890,000
1927	15,791,000	11,280,000
1928	60,228,000	43,020,000
1929	199,104,000	136,374,000
1930	254,844,000	168,104,000
1931	186,600,000	120,387,000
1932	177,812,000	118,591,000
Total	896,945,000	599,646,000

There are "sour" and "sweet" gases in the Texas Panhandle district. "Sour" gas is found largely in the line producing areas of the Borger district. "Sour" gas is also produced by some wells in Gray, Moore, Carson, and Potter counties. A "sour" gas contains from 5 to 200 grains of hydrogen sulphide per 100 cubic feet; a "sweet" gas contains 5 or less grains of hydrogen sulphide. Chemists state that most of the sulphur in the gas from the Granite wash zone is in the form of ethyl, prophyl, and butyl mercaptans rather than hydrogen sulphide. No "sour" gas is being taken by the pipe lines at this time.

The gasoline content of "lean" gas produced in the strictly gas areas of the Texas Panhandle varies somewhat. In general it can be stated that the lower a well is located on the north flank and the closer a well is to the oil-bearing areas, the higher the gasoline content of the gas. Natural gas

delivered to transmission pipe lines in the Panhandle district has an average gasoline content of 0.33 gallon per 1,000 cubic feet of gas.

Table X

Analysis of Panhandle Gas

	Composite Samples Wheeler County		Gas Well Carson County	Composite Sample Casinghead Gas, Gray County
	No. 1	No. 2		
Oxygen	0.22	0.40	0.40	
Carbon dioxide	0.00	0.10	0.30	
Nitrogen	1.59	2.10	1.80	
Methane	92.30	91.25	90.58	89.02
Ethane	3.09	2.80	3.70	4.02
Propane	1.81	2.09	1.37	4.20
Butane	.93	.82	1.08	2.90
Pentanes and heavier	.56	.44	.57	1.86
Gasoline content GPM	.329	.307	.342	1.068

The gasoline content of casinghead gas varies greatly, and seems to be partially reflected by the gas-oil ratio. The average gasoline content is about 0.75 gallon per 1,000 cubic feet. It ranges from 0.36 gallon to 2.00 gallons per 1,000 cubic feet.

Natural gas from reservoirs on the Bush dome in Potter County contains 2 per cent helium. This gas is treated at the United States Bureau of Mines helium plant for the recovery of helium.

Gas-Oil Ratio

Oil wells in the Panhandle have no uniform gas-oil ratio. The oil wells produce varying quantities of gas with the oil depending upon casing points and whether the gas strata are in contact with or separate from the oil strata.

Gas-oil ratios vary from 500 cubic feet of gas per barrel of oil to more than one million cubic feet of gas per barrel of oil. Data compiled in 1930 gave the western part of the Texas Panhandle fields a ratio of 29,450 cubic feet of gas per barrel of oil and the eastern part of the field a ratio of 9,780 cubic feet per barrel of oil. Average figures for such

a large area may be in error. We do not feel that an average gas-oil ratio can be applied to the entire producing area or even to individual pools.

Water

Surface water is generally encountered in the first 200 feet of formations drilled. Several other water-bearing horizons are encountered at various depths above the pay zones, depending on the location of the well. The first water-bearing horizon is encountered about 300-400 feet above the top of salt, and the second either in the top of salt or immediately above. No water is encountered from this last point to the oil bearing horizons unless it is pocket water, but water is uniformly encountered at sea-level depths. This lower water is known as bottom or edge water and is encountered around the edge of the oil-producing area. Where encountered about sea level the reservoir yields water freely when penetrated. It is a saline water high in chlorides and also contains some sulphates.

Status

There is an oil-water contact in the oil-producing areas along the north flank of the Amarillo structure and a gas-water contact exists along the west and south edges of the field. This was the original status when drilling began and only the oil-producing areas have been seriously affected by water encroachment and coning. Very little lateral encroachment has occurred except in areas depleted of oil and gas. Coning is the greater trouble in the oil areas due to too rapid withdrawals of gas and oil. There being no bottom water present high on the structure in the gas-producing zones, no encroachment and coning of water can occur as a result of rapid withdrawals and thus cause reduction of pressure.

The water level occurs in each producing stratum at or near sea-level.

Testimony of Harry F. Stevens

Available Reserves Under Present Canadian River Wells

Commission Counsel introduced testimony through Harry F. Stevens, Commission Engineer, with respect to the available reserves under present Canadian River wells.

Mr. Stevens is employed by the Federal Power Commission at Washington, D. C. in the capacity of Associate Engineer, and has been so employed since May 16, 1939. He stated his qualifications (Vol. 53, pp. 7366-7370) as follows:

"My college education consisted of three years at the United States Naval Academy, Annapolis, Maryland, and two years at the Colorado School of Mines, Golden, Colorado. I graduated from the latter in 1923 with a degree in Petroleum Engineering.

"My first employment after graduation, starting in June 1923, was with the Empire Oil & Refining Company at Bartlesville, Oklahoma, as a Junior Engineer. The plan of the Junior Engineering course was to provide experience in various branches of the oil and gas industry. My experience on this course consisted of assignments to various activities described briefly as follows:

"1. Keeping time and costs on a gas pipe line construction job in Kansas.

"2. Keeping time and cost on extension of city distribution system in Arkansas City, Kansas

"3. In charge of construction of a small oil pipe line near Cushing, Oklahoma. In addition to supervision, the work included the keeping of time and progress sheets, the book work related to the job, and testing of the line.

"4. Refinery assignments, Tulsa and Cushing, Oklahoma.

"5. General lease production work in the El Dorado field, Kansas.

"In June 1924, I was transferred to Henry L. Doherty Company, New York, where I remained until approximately March 1927. During this time, my work consisted principally

of statistical analysis and investigation of oil shale and oil shale processes.

"In March 1927, I was transferred to Empire Oil & Refining Company at Bartlesville, where for a year I was engaged in search and investigation of oil producing properties which might be repressured. Also during this year, I worked out a unit plan for production of oil and gas.

"In the first part of 1928, I was temporarily transferred to Cities Service Gas Company for the purpose of testing and reporting on the production of Missouri-Kansas Pipe Line Company. I was then permanently assigned to Cities Service Gas Company for the purpose of developing underground gas storage in depleted fields, for their system. During this period, extending to October 1936, I participated in every phase of this activity, from investigation through control of fields, testing of fields, and repair of wells to analysis of operation, and wrote approximately sixty engineering reports in connection with the work. During the work on gas storage, the company put into operation three gas storage projects at strategic points in its system for relief of peak load or emergency conditions. Its total capacity, I believe, was and now is the largest in the country for the purpose to which it is devoted. A fourth project was about to be put in operation at the time I left the employ of this company. During the period of work on gas storage, all methods of gas storage were investigated and reported. The analysis of gas storages dealt with inputs and withdrawals of gas and with the corresponding pressure changes, for the purpose of determining whether any gas was being lost from the structure. This analysis, each time it was done, constituted essentially an estimate of reserves. In the latter part of the period with Cities Service Gas Company I also made the monthly production report for the company.

"The companies listed in the foregoing covering experience from June 1923 to October 1936 were subsidiary companies of Cities Service Company, except Henry L. Doherty & Company, which was a management company for other Doherty interests.

"In October 1936 I went with Stanolind Oil & Gas Company, Tulsa, Oklahoma, as a Petroleum Engineer. My

work with this company consisted of preparation of engineering reports on petroleum engineering problems, described briefly as follows:

"1. Geological and engineering study of salt domes;

"2. Investigation of and recommendations for solution of current production problems from both physical and economic points of view;

"3. Recommendations for development, from both physical and economic points of view;

"4. Analysis of reports from field offices, and recommendations thereon;

"5. Analysis of well spacing problem—siliceous lime fields of Kansas;

"6. Investigation of and proposals for development of new oil fields with respect to economics of unitized development and to conservation of resources;

"7. Analysis of the unit principle of development with respect to equity of all parties concerned;

"8. Repressuring investigation of a Permian lime oil field, Texas;

"9. Proposals on exploitation of new markets for oil products.

"From May 16, 1939 to the present time I have been employed by the Federal Power Commission as Associate Engineer. My duties for this period include the following:

"1. Collection of the equivalent of approximately 30,000 pages of data on the Panhandle Texas gas fields, covering approximately six months;"

This parenthetically is the same work referred to by Mr. Hammer in his discussion of experience. We were both on that assignment.

"2. Discussion with representatives of numerous companies concerning various problems relating to the Panhandle gas field;

"3. Analysis of Panhandle field data, and preparation

of exhibits for the current hearings involving the Canadian River Gas Company and the other companies involved."

Q. Mr. Stevens, in connection with your qualifications, the last paragraph on Page 1 and continuing to Page 2, where you refer to your work in connection with the study of underground storage, where you speak of the storage gas, do you mean underground storage?

A. Yes.

Q. In natural reservoirs?

A. Yes.

Q. That work is still being carried on?

A. Yes, it is. They are using those projects.

Q. Of course, in your qualifications you spoke of storage and I want it clearly understood that it is underground storage of gas in natural reservoirs.

A. That is right.

Mr. Stevens prepared and submitted Exhibit 182, and testified with respect thereto (Vol. 53, pp. 7371-7386) as follows:

Q. I will ask you whether you have prepared an exhibit entitled "Estimate of Recoverable Gas Reserves"?

A. Yes.

Q. And when you speak of present wells, as of what time do you refer to?

A. I refer to December 31, 1939.

Q. Is this the exhibit I now show you?

A. Yes.

Mr. Lange: We would like to have this marked for identification.

The Trial Examiner: It will be marked for identification as Exhibit No. 182.

(Exhibit 182, Witness Stevens, marked for identification.)

By Mr. Lange:

Q. Mr. Stevens, will you turn to Exhibit No. 182, turning to the first page in that exhibit where you have included a written statement?

A. Yes.

Q. Will you read that statement into the record?

A. "This exhibit is prepared for the purpose of esti-

mating the reserves of gas that will be recovered by Canadian River Gas Company from their present wells, as differentiated from recoverable reserves under leases, the latter to be recovered by present wells plus future development.

"Recoverable reserves are estimated on production data for the last four years and pressure data for the last five years. In the matter of pressure, the 1935 pressure is, of course, the pressure point at which the 1936 production begins. The reason for adopting production data and related pressure data for the last four years is that for this period field data are considered to be the most dependable. The pressures are mid-year pressures taken by the Railroad Commission of Texas, and the production figures are for the year ending July 31, comparable to the time at which the pressures were taken.

"A general reason for considering the production and pressures of the total quadrants of which Canadian River wells have a part, is that in projecting into the future some weight is given to the interrelation of factors affecting production for any given part of the wells, such as the Canadian River wells.

"Recoverable reserves have been estimated by quadrants, the same method being used for all quadrants. The method is described as follows:

"1. The production for the total quadrant is accumulated by years for the last four years and plotted against corresponding pressures. The 1935 pressure is plotted against zero production. Through the points so plotted is drawn the mean curve which is extended to intersect a line drawn through the assumed abandonment pressure of 25 pounds gauge at the well head.

"2. The reading of this intersection on the horizontal scale is the estimated recoverable reserves for the quadrant as of July 31, 1935.

"3. To obtain the recoverable reserves for the wells as of July 31, 1939, we subtract the production for the period of July 31, 1935 to July 31, 1939, giving the future expectancy for the latter date.

"4. After consideration of the ratio of Canadian River well production to the total quadrant production, it was found that the overall ratio existing for the year 1939 was approximately the same as if the period of the last three years was considered. In any event it would appear that the 1939 ratio should be given major weight in determining what proportionality should be assumed for the future. The ratio of Canadian River production to total quadrant production was then assumed as that ratio which could be expected for the future on the premise that they would continue to capture that proportion of the recoverable reserves of the quadrant. This ratio was calculated from the two production data columns on the left side of the tabulation.

"5. The recoverable reserves, or future expectancy, of the quadrant was then multiplied by the ratio calculated as described, to obtain that share of the quadrant recoverable reserves that will be produced by the present wells of the Canadian River Gas Company. The curve showing the Canadian River recoverable reserves is drawn starting at zero, to provide direct reading without subtraction of any production. Any point o the Canadian River curve can be confirmed by applying the ratio to the value of a similar point on the quadrant curve after the quadrant production is subtracted.

"The quadrant reserves are totaled and shown at the bottom of the tabulation.

"A curve showing the composite recoverable reserve, or future expectancy, of all the Canadian River wells is included along with the quadrant curves.

"It will be noted that in the case of every quadant, the mean through the plotted points is drawn conservatively.

"That is, it would have been easily possible within the bounds of reasonableness to drawn our mean at a gentler slope, which would result in its intersection with the 25-pound line at a higher reading for recoverable reserves.

"The analysis carried out as described summarizes to the following conclusions:

"1. Recoverable reserves under present Canadian River wells, 2,186.7 billions of cubic feet. (14.65 pounds.)

"These recoverable reserves are as of July 31, 1939.

Three new wells have been drilled between this date and December 31, 1939. These wells have no production record on which to base an expectancy; therefore, they are estimated on the basis of the 91 wells operating as of July 31, 1939.

"The recoverable reserves of the three new wells on this basis is 72.089 billions.

"Total recoverable reserve, December 31, 1939, including production for August 1, 1939, to December 31, 1939, 2,258.789 billions."

Q. In each instance you mean cubic feet of gas?
A. Yes.

"Less Canadian River production August 1, 1939, to December 31, 1939, 19.940 billions.

"2. Total Canadian River recoverable reserves, December 31, 1939, 2,238.849 billions.

"The tabulations and curve sheets constituting part of this exhibit are listed below:

"Tabulation—Estimate of Recoverable Reserves.

"One curve sheet showing plotting and extrapolation of data for summation of the quadrants in which Canadian River Gas Company has production.

"Nine curve sheets showing plotting and extrapolation of data by individual quadrants.

"Each of the curve sheets includes a curve for the Canadian River wells alone."

Q. Now turn to the first curve sheet following this written statement, Mr. Stevens, and briefly explain it.

A. The group of two curves shows first the extrapolated production pressure plottings of all of the wells in all of the quadrants in which Canadian River Gas Company has wells. The solid curve is the curve for those total wells; the dashed line is the curve for Canadian River's share alone; the circled points represent the plotting referred to of accumulated production for the four years ending July 31st, 1939, against corresponding pressures for those years, the pressure data and the production data are mid-year

data; that is, for the year ending July 31st for the years in question.

Q. Now, you have following that the nine curve sheets referred to in your written statement. Can you give a brief explanation of all of those and the purport of those curves?

A. All of these curves comprising the nine curve sheets are calculated and plotted in the same manner. I will explain the first one. It is also illustrative of the other eight curves.

This curve sheet—the curves thereon are plotted and the data accumulated in exactly the same manner described for the composite curve with the exception that it refers to Carson County, Quadrant 4. That factor which you see at the top center of the page is repeated on all of them and is the ratio of Canadian River Gas Company's production in 1939 to the total quadrant production for that same year. That represents the relation between the dashed curve of Canadian River Gas Company alone to the total quadrant curve which is shown in solid.

Q. Did you proceed in the same fashion in the construction of the following curves? Maybe you had better explain the next one.

A. They were drawn in the same manner.

The next one is for Hartley County, Quadrant 1, that being the only quadrant in Hartley County. This curve presents a little different appearance than the other in that it has several lines back and forth across the page which is simply a method of parallel projection which will be evident upon inspection. You will notice in this case the dashed line representing Canadian River Gas Company's wells alone is parallel to the solid line, whereas in other cases it is not. The reason for that is that Canadian River Gas Company has all the wells in that quadrant and the factor is one.

After that first curve was drawn it would have been possible to leave it there without drawing the dashed curve, but it would have been necessary to subtract the accumulated production through 1939 from any total reading that you would read at the intersection of the 25-pound line. And the purpose in this case of drawing the dashed line was simply this, that by starting it at zero whatever reading is

read at the intersection of the 25-pound line is the reading of the recoverable reserve direct and does not require any subtraction of accumulative production through 1939.

Q. Now, the next curve sheet refers to the Hutchinson County Quadrant 3.

A. Yes.

Q. Will you read the description of that and its purport?

A. That refers, as indicated, to the third quadrant in Hutchinson County. It is of the same general nature as the other curves which have already been described. This sheet has a radically different pattern than the one described for Hartley County. You will notice the lack of parallelism between the dashed curve and the solid line; the reason for that is that Canadian River Gas Company's production in relation to the quadrant reserve is not one. It only represents a portion of the quadrant production which as you will see in the top center of the page is 1167 of the Canadian River Gas Company's production to the quadrant production for 1939 which ratio was applied to the quadrant curve to obtain the Canadian River Gas Company's curve alone. By "Canadian River Gas Company's curve," I mean the curve for wells that the Canadian River has in Quadrant 3, Hutchinson County.

Q. Each of those curves as situated in the extension?

A. Yes, sir.

Q. Turn to your next curve, Moore County, Quadrant 1.

A. This curve was constructed in the same manner as the others. There is really nothing new to describe except possibly to note that each of these quadrants has a slightly different pattern relation between the Canadian River's curve and the total curve. That is entirely a matter of what the factor is, the ratio of Canadian River's production to the total quadrant production.

Q. And the next is Moore County, Quadrant 2.

A. That curve sheet was built up in the same manner as previously described. There is really nothing more to say about that except that it has been constructed in the same manner.

Q. Is there any particular explanation that you deem necessary with reference to the three remaining curve sheets in the exhibit?

A. No, there is nothing with respect to those three quadrants that should be mentioned.

Q. Turn to the typewritten table that appears following the curve sheet and explain the contents and import of that in connection with your exhibit.

A. The tabulation simply represents the summary of data used in plotting and constructing the curve already described. You will note that it is divided by the quadrants. These quadrants are the same area divisions as adopted for studies previously submitted in the exhibit presented by Mr. Hammer.

The method of obtaining this ratio of Canadian River's production to the total quadrant for the year 1939 is shown by the first two columns, one being the production for Canadian River Gas Company and one being for the total quadrant and a simple division gives you the ratio which is shown in the next to the last column.

Q. That is the column headed "Ratio: Canadian River Gas Company Production to Total Quadrant 1939"?

A. Yes, starting with .05933 and the next one is 1.000.

The third column of figures, excluding the dates, consists of accumulative total quadrant production for the year noted in the first column. That gives the figure to be plotted against the pressures which are shown in the next column to the right. There is the essential data on which the solid line curve is plotted.

Q. You are referring to your solid line curve preceding this table?

A. Yes, sir, that is right. The next two columns refer to the number of wells. Those figures contained therein represent the number of wells for the years in question, both as to Canadian River Gas Company and for the total quadrant.

The next column to the right, headed "Future Expectancy, 7-31-35," is the intersection of the curve drawn on the data previously described with the 25-pounds assumed abandonment pressure line. That figure includes all production which has been involved in the plotting of the curve. That production is shown in the next column to the right headed

"Withdrawals, Total Quadrant, for the four years in question."

It is then necessary to subtract that figure from the "Future Expectancy" which has to be done to arrive at the future expectancy as of 7-31-39. That is shown in the next column to the right. It is to this figure that we applied the ratio of Canadian River's production to the quadrant production for 1939, this ratio having been already calculated from the first two columns on the extreme left.

Multiplication of the "Future Expectancy" of total quadrants, 7-31-39, by this ratio gives the last column of figure shown in the tabulation or the futures expectancy of Canadian River Gas Company wells as of 7-31-39. Those totals, as you will see in the lower right-hand corner, amount to 2,186.7 billion cubic feet. It is from this 2,186.7 billion cubic feet that we proceed to the end of 1939.

As stated, that calculation was accomplished by taking the average of the 91 wells which simply means dividing 91 into 2,186.7 billion cubic feet and multiplying it by 3 for the new wells that were added in the latter part of 1939, which figure is 72.089 billion cubic feet.

Q. You are now relating that fact to the third page of your written statement?

A. That is right.

Mr. Lange: The pages are not numbered. They should be numbered.

The Trial Examiner: The reporter will make the changes.

By Mr. Lange:

Q. I think I interrupted you, Mr. Stevens.

A. I believe we were at the point of adding the expectancy of three new wells drilled in the latter part of 1939 which figure was obtained by multiplying the average expectancy of 91 wells by 3, constituting 72.089, which added to the expectancy as of 7-31-39 gives 2,258.789 billions as of 12-31-39, but including the production for the year, including the production for that part of the year between August 1, 1939 and December 31, 1939 in the amount of 19 940 billions cubic feet.

Of the previously stated expectancy that is the amount that has already been used up by production, and, consequently has to be subtracted. That subtraction gives you 2,238.849 billion cubic feet which is the total of Canadian River Gas Company's recoverable reserves as of December 31, 1939.

Q. Recoverable reserves of gas?
A. Yes.
Q. As of December 31, 1939?
A. Yes.
Q. Now, in connection with this study, Mr. Stevens, I will ask you whether subsequent to the preparation of Exhibit 182 you prepared a page supplementing the study down through December 31, 1940.
A. Yes, I have.

Mr. Lange: I suggest, Mr. Examiner, that this document be marked for identification as Exhibit No. 182-A.

The Trial Examiner: It will be so marked.

(Exhibit 182-A, Witness Stevens, marked for identification.)

By Mr. Lange:

Q. Now, Mr. Stevens, will you please read this supplemental page identified as Exhibit No. 182-A into the record?
A. "Canadian River Gas Company, Supplement to Estimate of Recoverable Gas Reserves, Present Wells.

"The above named exhibit was confined to wells existing as of December 31, 1939."

Q. That refers to Exhibit 182?
A. Yes.

"Three new wells were drilled in 1940. The recoverable reserves or expectancy of these new wells should be added to that of the wells previously considered, as of December 31, 1939. The purpose of this supplement is to extend the scope of the estimate of recoverable reserves to December 31, 1940 by the addition of expectancy of the three new wells of 1940, followed by the subtraction of production from all wells during 1940.

"As the new wells have no production record on which to base a future expectancy, the expectancy of each will be considered to be the average of other Canadian River Gas Company wells. This assumption is considered very conservative, as the average capacity of the three wells is approximately 43 million cubic feet, which is more than twice the average capacity of the company's other wells.

"Total Canadian River recoverable reserves, December 31, 1939, 2,238,849 billions;

"Acreage recoverable reserve, 94 wells, December 31, 1939, 23,817,543 * * *"

Q. Shouldn't there be a period there between "23" and "817,543"?

A. If we are talking in billions, as these other figures are, the point is after the "23." It should read "23.817,543."

Q. Do you want to make that correction?

A. That is supposed to be a period.

Q. The period would be after the "23"?

A. Yes.

The Trial Examiner: There appears to be a period on my copy but perhaps the official copy may not show one. In any event, it will be corrected to correspond with the witness' testimony.

The Witness: "23.817,543 billions.

"Additional recoverable reserve, 3 new wells, 71.453 billions.

"Total Canadian River recoverable reserves, December 31, 1940, including production of all wells for 1940, 2,310.302 billions.

"Less Canadian River production, 1940, 49,000 billions.

"Total Canadian River recoverable reserves, December 31, 1940, 2,261.302 billions."

By Mr. Lange:

Q. Are there any further explanations you deem necessary in connection with this supplement?

A. I don't think so. It was calculated in the same manner from one date to the next—to the final date, the final

date being 12-31-40. It was calculated in the same manner as we went from 7-31-39 to 12-31-39. This procedure is necessary because before any new wells may be added in any interval for which there is no production, we must necessarily consider those new wells to be of average expectancies since they have no production record upon which expectancy can be predicted.

Mr. Lange: That is all for the present.

The Trial Examiner: Mr. Stevens, just to make this record a little clearer here, going back to that figure we were just discussing, there appears to be a comma between 7 and 5. That comma should be stricken out, shouldn't it?

The Witness: Well, to make it correct mathematically, it should be stricken; however, if the decimal is firmly established after 23, it sufficiently identifies the figure.

Mr. Spencer: You are carrying out the decimal point to six places?

The Witness: We did there. It isn't essential and—

Mr. Spencer: But you do that here—carry it out six places?

The Witness: Yes.

The Trial Examiner: I think that is understandable, then.

Mr. Lange: I think that is all for the present.

Mr. Stevens further testified (Vol. 62, pp. 8690-8697) as follows:

Mr. March: Mr. Examiner, in checking over the record we found that Mr. Stevens left out one essential explanation in his exhibit that he should have given on direct, and an explanation that we failed to ask him about. I might ask him that question with Mr. Keffer's consent at this time.

Mr. Keffer: All right.

Voir Dire Examination.

By Mr. March:

Q. Mr. Stevens, did you use the same quadrants in

figuring the reserves under wells of Canadian River's acreage as did Mr. Hammer?

A. In general, yes, and with one exception.

Q. You mean in general, with just one exception?

A. With one exception.

Q. What quadrant was that?

A. That was the Quadrant 3, Hutchinson County.

Q. Just how does your treatment of that quadrant so far as that is concerned differ from Mr. Hammer's? Just what portion of the quadrant do you not include in your exhibit, your calculations—in what portion of the quadrant?

A. Hutchinson Quadrant 3 is a long quadrant vertically laid out on the map, and the Canadian River's wells are in the southwest portion of that, and principally for that reason consideration was made of that part of the quadrant adjacent to and inclusive of Canadian River's wells, and that part of the quadrant so described was taken as the quadrant. In other words, it was really a new areal designation for Quadrant 3 with respect to Canadian River's wells.

Q. Because Canadian River's wells were not in the northern part of the quadrant?

A. That is right.

Q. And were confined to an area in more or less the southern or southwestern part of the quadrant?

A. Yes.

Q. You will have to read for the record just exactly the wells listed in your working papers you did take in that quadrant.

A. Those wells are as follows: Johnson A-1; Bivins B-1; Bivins B-2; Bivins B-4; Dunaway A-1; Bivins B-5; Bivins B-6; Bivins F-1; Bost A-1 and Bost B-1—

Mr. Spencer: Can I interrupt you a minute?

Mr. March: Yes.

Mr. Spencer: Those are all Canadian River's wells you have read into the record so far?

The Witness: Yes, they are, that I have read so far.

Mr. Spencer: When you come to wells that are not Canadian River's wells, will you so indicate so we can get

a list of those? We know our own wells but we don't know the other wells that you have.

The Witness: Dunaway B-1, Dunaway A-2. That is all.

Mr. March: Those are all of the wells in that quadrant you utilized?

The Witness: Yes.

Mr. Spencer: Do I understand you have used no wells except Canadian River wells?

The Witness: I have used no wells but Canadian River wells.

By Mr. March:

Q. Did you designate the approximate location of those wells—you have already done that?

A. I have already done that. However, it should be pointed out that in determining the ratio to be applied we did consider the ratio production in terms of the entire quadrant which amounts to .1167 fully finished. Those things as described are the essential differences from the areal designation of Quadrant 3 on the maps.

Mr. March: Mr. Examiner, I unthoughtedly proceeded without renewing our offer of Mr. Hammer's exhibits, which was to be acted upon this morning. We renew the offer of those Exhibits 179, 180 and 191.

The Trial Examiner: Let's get through with Mr. Stevens first.

Mr. March: It will probably take all day. We want to get rid of Mr. Hammer's exhibits.

Mr. Spencer: I would like to ask him a few questions about the very thing you have injected for the moment.

Mr. March: Mr. Examiner, do I understand that the Examiner is not going to rule on Mr. Hammer's exhibit today?

The Trial Examiner: Well, let's go along with Mr. Stevens and see how we get along. I would like to have all of this in one place in the record if possible.

Mr. Spencer: As a matter of fact, I think that might expedite the whole procedure because whatever objections we have will be aplicable to both exhibits taken at the same tme.

Mr. March: There is no relation as to the two exhibits. We don't think it will expedite things a bit. If that is satisfactory to the Examiner it will be satisfactory to us.

Cross Examination (Continued).

By Mr. Spencer:

Q. Mr. Stevens, you used only Canadian River's wells in computing reserves, is that the distinction you made here? You use all of the wells or production in determining the ratio and for determining reserves under Canadian River's wells?

A. There are some other wells in there. I didn't read the complete list here. On my next page is a recapitulation which does include the other wells. This tabulation here is only for Canadian River production and there are some other wells which I should add to that of other companies.

Q. Will you read those slowly so we can write them down?

A. Yes.

Mr. March: I will say, Mr. Spencer, when we went over this last night we didn't have the working papers to check it as we should have.

Mr. Spencer: That is all right.

The Witness: These are the additional wells of other companies: Phillips N. R. Johnson No. 1—

By Mr. Spencer:

Q. All right.

A. Texoma Johnson A-1-G; Panhandle Bost 1-9—that is Panhandle Eastern—Panhandle Bost 114; Panhandle Bivins 91; Texoma C. Johnson 1-P; Texoma Johnson 1; Phillips Claire 1; Danube Wheatley Johnson 1; Huber Crudgington No. 1—

Q. What was the last one?

A. Huber Crudgington No. 1

A. Yes. Huber Dunaway 1; Phillips Sanford A1; Phillips Sanford No. 1; Phillips Yantes No. 1—

Q. I beg your pardon?

A. Phillips Yantes No. 1.

Q. All right.

A. Huber Dunaway No. 2; Phillips Burl No. 1; Phillips Eddy No. 1; Phillips Fromma No. 1; Phillips H. E. Johnson No. 1; Sinclair Prairie Johnson 1-D; Phillips Snow No. 3; Texoma Deahl 1-E.

Q. Is that all, Mr. Stevens?

A. That is all in that area combined with the previously stated Canadian River wells.

Q. That gives you a total of how many wells that you used in that quadrant?

A. 35.

Q. And out of that how many belonged to Canadian River?

A. 13.

Mr. Spencer: We find a total of 34 but perhaps we missed one. We can check that with you later. It doesn't need to be done now.

The Witness: Well, now it is possible that I have 34.

Mr. Spencer: Well, we can check that later. It is just a difference of one well. We can check it with your working papers to see whether we have them all.

Mr. Examiner, I wonder if we could get Mr. Hammer's quadrant map back up on the board again?

The Trial Examiner: Let's see. That is Exhibit 180, is it not?

Mr. Spencer: Exhibit 180.

The Trial Examiner: All right, we will do that.

By Mr. Keffer:

Q. On Quadrant 3, Hutchinson County, Mr. Stevens, I believe you just stated that you considered only 35 wells in the area, is that right?

A. Yes, sir.

Q. How many wells are there in the total area that

A. I don't recall that.

Q. You know it is more than 35, don't you?

A. Yes, sir, it is a considerable distance from this area.

Q. Would you hazard a guess that there are as many a hundred wells?

A. I wouldn't hazard a guess, but it may be more less.

Q. I wonder if your working papers won't reflect t wells that you eliminated?

A. I have, I think, a list of those wells here in t working papers; however, it is immaterial to the proble The reason they were not considered—

Q. That wasn't my question. I want to know ho many wells are in the area, or in the quadrant as a whol as compared to the number of wells you actually used.

A. I don't recall that from memory.

Q. I am wondering if you couldn't get that figure fro your working papers.

A. I think I possibly could.

The witness considered the production and pressures of the total quadrants in which Canadian's wells are located (except that he did not consider all of Quadrant 3 Hutchinson County, but only a small portion in the southwest corner of such quadrant). (Vol. LXII, pp. 8789-8791.)

Recoverable reserves were estimated by quadrants. He accumulated the total production by years for each quadrant from mid-year 1935 to mid-year 1939 and from this a curve was plotted and extended to intersect a line drawn through an assumed abandonment pressure of 25 pounds gauge at the wellhead. The recoverable reserves are determined by reading from this curve. The first set of curves contained in Exhibit 182 represents a composite curve for the total quadrants as represented by the solid line, which represents the total expected recovery by all producers owning reserves in the various quadrants. The dashed line represents the estimated recoverable reserves of Canadian only from Canadian wells now drilled.

The witness determined the ratio that Canadian would recover from each of the various quadrants by considering the relation of its production in 1939 to the total production from the quadrants for that year, and assumed that in the future Canadian would continue to capture this proportion of the recoverable reserves of each quadrant. This ratio as determined by the witness averaged throughout all of the quadrants is 45.30%, or stated in another way, .4530 as shown by the twelfth column of the last table of Exhibit 182. The witness stated, however, on cross-examination that if quadrants had not been considered and the over-all ratio determined that this would have given a ratio of approximately 38% rather than the 45.30% utilized by witness. (Vol. LXII, p. 8781.) The calculation, as made by the witness, and which is shown by the dashed line on the composite curve, indicates that Canadian from its present wells will recover 2,186 trillion cubic feet to an abandonment pressure of 25 pounds.

The witness stated on cross-examination that although he had assumed a wellhead abandonment pressure of 25 pounds as the basis for his calculations, that this was predicated upon his belief that it would be physically possible to pro-

duce the wells down to 25 pounds wellhead gauge pressure (Vol. LXIII, p. 8991) but that he did not know much from actual experience about the correct abandonment pressure from a physical standpoint and that he did not know the number of wells that had heretofore been abandoned in the Texas Panhandle Field, or the pressures obtaining at the time of abandonment (Vol. LXIII, pp. 9013, 9014). The actual pressures at which wells will be abandoned will be determined by the economic conditions existing at the time, and he had made no particular study of this phase of the matter (Vol. LXIII, p. 8990) and he had made no assumption of the economic abandonment pressure at this time. (Vol. LXIII, p. 8991.)

Stevens stated that his calculations of reserves, as reflected by Exhibit 182, was simply the application of the pressure-decline method in principle to the estimation of reserves. He plotted the pressures and gave no consideration specifically to the amount of decline for any two successive years. (Vol. LXII, pp 8697, 8698.) He made no study of the geology applicable to the area and neither did he study permeability nor porosity nor sand thickness, but did consider permeability and porosity to the extent that there could be no production if there were not some porosity and some permeability. (Vol. LXII, pp. 8699, 8739-8744.) He did not study drainage. (Vol. LXII, p. 8812.)

He included in his study all of the wells located in all of the quadrants in which Canadian had acreage (except Hutchinson County, Quadrant 3). He did this to incorporate the effect of the production of other companies on Canadian wells—whatever the effect was. (Vol. LXIV, p. 9068.)

The solid line, being the top line on the first set of curves shown in Exhibit 182, represents the total recoverable reserves estimated as recoverable from the present wells in all the quadrants. This curve indicates that all of the wells in all of the quadrants will produce 5.2304 trillion cubic feet of gas to 25 pounds abandonment pressure. The points indicated by 35, 36, 37, 38 and 39, represent the pressures obtaining for the years 1935 to 1939 inclusive. The witness stated that he had his answer before the line was

drawn and he started at the accumulated production total of 5230.4 and drew his line backwards in order to get a straight line. (Vol. LXII, pp. 8868-8869, Vol. LXIII, p. 9059 and Vol. LXIV, p. 9172.) He stated that if his estimate had been made a year earlier and he had not had his 1939 pressure point that the curve would have been almost a horizontal straight line if he had given any weight to the 1935 and 1936 pressure points (Vol. LXII, pp. 8861-8862) and that if he had taken the pressure points for 1938 and 1939 only and had drawn a line from the center of the circle representing 1938 to the center of the circle representing 1939 that he would have had a much more precipitous decline than his curve shows as actually drawn. (Vol. LXII, p. 8863.) He stated, however, that he disregarded the 1935 and 1936 pressure points because waste was existing in the field at that time and he did not believe that these pressures represented a proper build-up. He says that the waste occurred where carbon black and gasoline plants were situated but further stated that he did not know of a single plant of either character located in the area in which he was studying and finally stated that whatever the reason was the pressures for 1935 and 1936 fell below the line as he had drawn it and he had, therefore, ignored them and it would have been just as well if he had not plotted them on his graph paper. (Vol. LXII, pp. 8836, 8846-8854.) He stated again that there was a reason for the 1935 and 1936 pressure points falling below the curve and that the reason, whatever it was, was unimportant. (Vol. LXII, p. 8860.)

The witness was then cross examined as to the curves drawn for each quadrant. He again stated that he had ignored the 1935 and 1936 points. He stated that nature determined the points and that they are good or bad depending upon the proximity of the points to a straight line and if a particular point was above or below a straight line that it should be ignored (Vol. LXII, pp. 8879-8880) and that he selected the points as the basis for his curves which would most nearly represent what the curve ought to be, (Vol. LXII, pp. 8885, 8886) and that the points did not determine his curves but did influence them. (Vol. LXIII, pp. 8895, 8896.) The witness stated that the curves as to

each quadrant were drawn about the way that he thought they ought to be. (Vol. LXIII, p. 8896.)

He stated again that the composite curve was drawn to the predetermined answer, (Vol. LXIV, p. 9172) and without regard particularly to the points and that it could have been drawn so as to more accurately reflect the 1937, 1938 and 1939 points, and if this had been done it would have shown a less reserve than the way it was drawn. (Vol LXIV, p. 9171.)

The witness stated that he had utilized only a portion of Hutchinson County Quadrant 3 because he secured a better looking curve by doing this. He had first drawn his curve for this quadrant and based the same upon the production and pressure data for the entire quadrant but this gave him a slightly ascending curve due to the fact that the quadrant as a whole showed a higher pressure in 1939 than in 1935. (Vol. LXII, pp. 8789-8794.) He stated that Hutchinson County Quadrant 3 was draining gas from Moore County Quadrant 1, and that the pressure of Hutchinson County Quadrant 3 had increased notwithstanding it had produced 172 billion cubic feet of gas over the four-year period studied and had produced more gas than any other quadrant under consideration and it increased in pressure notwithstanding it was also losing gas by migation to the eastward. (Vol. LXII, pp. 8795-8809.)

As heretofore stated the dashed line on both the composite curve and the curve for each quadrant represents the percentage of the total production from the quadrant as a whole and from each individual quadrant that the witness estimates will be produced by Canadian.

The witness stated that the ratio was determined by the summation of quadrants but that it wouldn't have made any difference if he had eliminated the quadrants entirely and had arrived at a ratio by considering the total over-all production of Canadian as related to the total over-all production from all the quadrants. (Vol. LXII, pp. 8776-8779.) This procedure gave a ratio of .4530, or stated another way, a percentage of 45.3%. (See tabulation last page of Exhibit 182.) He was then reminded of the fact that for the year 1939 his Exhibit 182 showed a total produc-

tion for Canadian of slightly in excess of 44 billion and that the total production from all of the quadrants was in excess of 117 million. He stated that this was true and that although he had arrived at a percentage figure of 45.3% based upon the 1939 ratio by means of the summation of the quadrants that he would only have gotten approximately 38% as the ratio or percentage applying to Canadian if he had disregarded quadrants and that this would have given an expected recoverable reserve for Canadian of approximately 1.820 trillion instead of approximately 2.186 trillion, as indicated by the summation of the quadrants. (Vol. LXII, pp. 8779-8782.)

The witness then read figures into the record showing the ratio for the various years of the entire period studied. The production figures, however, were apparently based upon calendar years. This testimony is set out as follows:

ar	Canadian Production	Total Production	Canadian Ratio
36	43.590,010 billion	79 billion plus	50% (Approximately 55%)
37	46.610,252 "	99 "	plus 47%
38	42.483,068 "	106 "	plus 40%
39	44. " plus	117 "	plus 37% plus

The witness then stated that the ratio of Canadian's production to the total production had gone down progressively from more than 50% in 1936 to slightly more than 37% in 1939, and that from the entire area Canadian was producing a smaller and smaller percentage of the total production. The witness ignored the very decided downward accelerated decline in the ratio but stated his ratio of .4530 was based on 1939 production and that it was a weighted ratio. The record does not reflect just what the weighting medium was. (Vol. LXII, pp. 8827-8832.)

The witness stated that although the ratio had been getting smaller and smaller for the past four years, he could not agree that it would likely be still smaller in 1940 and 1941 because the markets might increase (Vol. LXII, p. 8833) but that he had not investigated market outlets of other companies producing in the same area and that the curve representing the ratio was extended into the future without any changes whatsoever and was based upon 1939 performance.

(Vol. LXII, pp. 8834-8835.) He assumed that the present ratio would not change. (Vol. LXIII, p. 8900.) He also stated that although his calculations assumed that Canadian would continue to produce 100% of the gas in Hartley County, he knew that other companies had substantial acreage in that county but that much of the additional acreage was sour gas acreage and he had made no study as to carbon black markets. He assumed there would be no change in the ratio because he did not think it was within the realm of probability that the sour gas acreage would be developed. The Canadian also had a very high ratio, approximately 80% in Moore County Quadrant 3, and although he knew Canadian owns only about one-fourth of the acreage in this quadrant, still he did not consider that the ratio would change. He stated, however, that if the ratio did change in Hartley County and in Moore County Quadrant 3 that his factor of .4530 would change even though Canadian continued to produce the same volume of gas. (Vol. LXIII, pp. 8901-8911.)

The witness stated that as Canadian drilled additional wells it would increase its recoverable reserves and estimated that for three new wells added after mid-year 1939 that Canadian's recoverable reserves had been increased approximately 24 billion cubic feet per well. (Exhibit 182-A.) He stated also that his dashed curve, as shown in his various calculations, would be changed by the drilling of additional wells (Vol. LXIII, p. 8997) but then admitted that the drilling of additional wells would not change the dashed line no matter how many additional wells were drilled unless there was also a corresponding increase in market outlets or production (Vol. LXIII, pp. 9000-9002) and this being true one hundred more wells (or any number more) would not change his calculated reserve figure of 2,186 billion shown in the composite curve, Exhibit 182. (Vol. LXIII, p. 9004.) He also stated that neither any contemplated increase in production nor change in the ratio as represented by the various dashed lines had been taken into account in his study. (Vol. LXIII, p. 9005.) He said, also, that it was possible that conditions in the future might increase the present percentage assigned to Canadian, although he realized that at the present time it had been decreasing from year to

year. (Vol. LXIII, p. 9006.) Witness also stated that he had not changed his solid line being the composite curve as shown in Exhibit 182 by virtue of the drilling of additional wells in the entire area. He stated there were 178 wells in 1937 in the entire area, 207 in 1938 and 228 in 1939, and that although his solid composite curve was based upon 1937, 1938 and 1939 production figures that the line was not changed, or additional reserves indicated by reason of the drilling of the additional wells, and that if the conditions, as reflected by the producing data for those three years do not change in the future that the drilling of additional wells in the future will not increase the reserves (recoverable reserves), (Vol. LXIII, pp. 9006-9009); and finally, that unless additional wells did add additional reserves his estimate of 2.186 trillion recoverable reserves for Canadian would remain as the final figure. (Vol. LXIII, p. 8969.)

He also stated that the total loss in pressure for the year 1939 as shown by Exhibit 182 was 15.6 pounds and on this basis the present wells of Canadian would last approximately twenty years from August, 1939, and that the entire volume of recoverable gas would be produced by the end of that period. (Vol. LXIII, pp. 8970-8971.)

Stevens stated that Hammer's estimate of total reserves in Potter County Quadrant 3 was 448.272 billion, and that notwithstanding this fact he (Stevens) had calculated on his method that the present wells in Potter County Quadrant 3 would actually produce 525.3 billion cubic feet. He stated also that there were now 9 wells in Potter County Quadrant 3 and that the wells were spaced on the basis of one well to almost 4000 acres. (Vol. LXI, pp. 8671-8673.) He stated also that Quadrant 1 Potter County now had 24 wells with a spacing of one well to a little less than 2400 acres, and that everything else being equal the same number of wells in Quadrant 1 Potter County, should produce as much gas as an equivalent number in Quadrant 3 Potter County. (Vol. LXIV, pp. 9114-9118.) He also stated that Hammer's estimate of remaining reserves under Canadian acreage in Quadrant 1 Potter County, was 1,078,766,000 Mcf. while on the basis of Stevens' calculations the Canadian wells in this quadrant would produce only 340,500

billion cubic feet or but little more than one-third of the total remaining reserves owned by Canadian in this quadrant as estimated by Hammer. (Vol. LXIV, pp. 9142-9143.) He stated that drainage into Quadrant 3 was probably the reason that the present wells would produce more than Hammer's estimated reserves and that although he had not considered drainage he was of the opinion that drainage out of Quadrant 1 Potter County did not explain the fact that the present wells in that quadrant would produce less than Hammer's estimate of reserves. (Vol. LXIV, p. 9141.)

The reserve per acre in Potter County Quadrant 1, as estimated by Hammer, is in excess of 22 million per acre, while in Potter County Quadrant 3 the reserve estimate of Hammer is just a little more than 13 million cubic feet per acre. Stevens also stated that the richer the area the greater the production per pound loss in pressure. However, the figures showed this to be just the reverse in so far as these two quadrants are concerned. (Vol. LXIV, p. 9140.) He also stated that the larger the area the greater the production per pound drop in pressure and then stated that the area of Potter County Quadrant 1 was greater than the area of Potter County Quadrant 3 and that the production per pound loss in pressure from Canadian acreage was approximately 1.3 billion per pound in Quadrant 3 while it was but .61 billion per pound in Quadrant 1. (Vol. LXIV, pp. 9126-9134.) He finally stated that he didn't know why a well was producing so much more in Quadrant 3 with a wider spacing and in a less prolific area than it was in Quadrant 1, and he didn't care what the reasons were. (Vol. LXIV, pp. 9137-9138.) He did state, however, that migration of gas out of a quadrant would affect the pressure and the less the migration the less the drop in pressure for any given volume of production. (Vol. LXIV, pp. 9141-9142.)

He again reiterated that there were not enough wells in Quadrant 1 to produce the reserves under the Canadian leases, and that the only basis he had for making this statement was the fact that his calculations showed the present wells would produce only approximately 340 billion cubic feet while Hammer's estimate of reserves showed almost three times this much gas in place and that if the present wells

would produce only two-thirds of the gas remaining at this time down to a pressure of 25 pounds wellhead that this meant he would have to have two-thirds of his 1939 pressure left at that time, and he realized that it would be absurd to expect this. (Vol. LXIV, pp. 9144-9148.) He also stated that when all present wells had been reduced in pressure to 25 pounds at the wellhead that there would likely not be more than 50 pounds pressure left at any point within the quadrant. (Vol. LXIV, pp. 9076-9109.)

The witness stated that the 24 wells in Quadrant 1 were pretty well distributed over the Quadrant. (Vol. LXIV, p. 9114.) The witness did finally state, however, that when all of the wells in Quadrant 1 had reduced in pressure to 25 pounds wellhead there would be very little more gas left in the quadrant above 25 pounds. (Vol. LXIV, p. 9111.)

Stevens further testified (Vol. 62, pp. 8778-8794) as follows:

Q. Mr. Stevens, you stated, I believe, just before the noon hour recess that it wouldn't have made any particular difference whether you had compiled your data quadrant by quadrant or whether you had just forgotten all about quadrant lines and cut straight across.

A. I don't think it would have.

Q. Now, as a matter of fact, isn't it true, Mr. Stevens, that due to the fact that you did consider quadrant by quadrant that you got a higher answer than you would have if you just cut straight across—got a higher answer as to recoverable reserves?

A. I don't think so, if you consider a reasonable drawing or extension.

Q. How is that?

A. I don't think so if you reasonably extended or projected the data of production versus pressure.

Q. Well, you did just that, didn't you, when you took it quadrant by quadrant?

A. Yes.

Q. Yes, all right. Now, you came out as shown by the last page of your exhibit, with a figure 45.3 per cent, didn't you, as applicable to Canadian River?

A. That was the result of the summation of all the quadrants, yes.

Q. How's that?

A. That was the result of the summation of all the quadrants.

Q. That's right, and, now, if you had cut straight through there and had not considered your quadrants at all, you would have come out with a smaller percentage, wouldn't you?

A. What do you refer to specifically?

Q. Well, I'll state it this way, that 45.3 that you show there in total on the bottom of the page, on the last page of your exhibit on the line next to the last on the right—

A. Yes.

Q. You show .453.

A. Yes.

Q. You conclude from that, therefore, that the present wells of the Canadian River will produce 45 per cent of the recoverable reserves under present wells in all of the quadrants, don't you?

A. Yes.

Q. All right. Now, you did that by taking quadrant by quadrant, didn't you?

A. And summating, yes.

Q. That's right. Now, if you had eliminated quadrants entirely and gone straight through with the same data instead of getting a production factor of 45.3 per cent for Canadian River over the whole area, you would have gotten a production factor of approximately 38 per cent, wouldn't you?

A. Yes, considered in terms of the total quadrants as a whole.

Q. Well, now, I am not sure that the question has been answered. Is it correct that you would have gotten 38 per cent of the whole?

A. You tell me how you arrived at that and I think I can answer it a little more clearly.

Q. All right, that's arrived at by taking your rock pressure declines—yes, by taking—take the first column over there on the left. That's 44.390268. What does that represent?

A. That's the total of Canadian River production.

Q. That is the total of Canadian River production.

The next figure is the total production from all the quadrants, isn't it?

A. Yes, that is right.

Q. All right, now, the Canadian River total during the period that you have used is 44 billion plus, isn't it—a little better than 44 and a third billion, is that right?

A. Yes.

Q. And the production for the whole quadrant is 117 billion plus, or a little less than 117 and a third billion, isn't that right?

A. That's right.

Q. Now, what percentage does the Canadian River's production bear to the whole? See if that isn't 38 per cent.

A. That is approximately correct.

Q. All right, then, if you had gone straight through and eliminated your quadrant lines, your factor for Canadian River would have been 38 per cent instead of 45-3/10 per cent you used, wouldn't it?

A. That is approximately correct.

Mr. March: Wait a minute, he wants to make an explanation in regard to his answer.

The Witness: I do not. I wish to shorten that.

Mr. Keffer: All right, maybe if we would just let the witness answer we would get along faster.

Q. Now, applying that to the total there, then you would have come out instead of with 2,186,000,000,000 for Canadian River, you would have come out with 1,820,000,000,000, wouldn't you, as a total recoverable gas under present wells?

A. On the basis of that, that is the case. Is it all right to make an explanation?

Mr. March: Yes. As far as Commission's counsel is concerned, I am sure the Examiner did not intend to rule that you could not make an explanation after you had answered the question to the best of your knowledge and belief.

The Trial Examiner: There is no objection if the witness feels that an explanation is needed, he will not be curtailed

from making such explanation, but the thing I am interested in is to avoid unnecessary explanations.

Mr. Keffer: All right, Mr. Stevens. I might say, that is the position of counsel for respondents, also, Mr. Examiner.

The Trial Examiner: Very well, Mr. Keffer.

The Witness: When I stated this morning that you would get approximately the same answer, that approximately envisaged the difference between that percentage you arrived at of 38 per cent of 45.3. Now, if we consider—while it is not necessary, as stated, to confine ourselves to quadrants, it is nevertheless thought that by breaking up the area into reasonable parts and the reasonable parts were in this case quadrants for the reason of being consistent as much as anything else, we could have taken irregular areas of most any description as long as we were reasonable in taking those areas, but the point of view and the opinion on this splitting up of areas, while the total does give an approximate answer, approximately similar to that using these quadrants, we believe in principle that to split up areas and summate them as is done here is more representative—I shouldn't say representative, it more accurately brings into close association the factors operating in a given area, those given areas being quadrant areas or some other similar areas. We simply take quadrants to be consistent and the quadrants that we take are the same as outlined in previous exhibits, consistency being the essential factor.

Now, we didn't try any other assembly—didn't see any necessity for it. This .4530 that you see down here, due to the varying percentages that Canadian River production bears in these different quadrants to the total quadrant production, that variation is boiled down and incorporated in this .4530 which might be determined a sort of weighted ratio. That is really what it amounts to, and that division of total area into some areas, as we have done here, is believed superior to taking the whole thing at one bite, although the answer by taking it all as a whole is not the same, but I wouldn't call it a serious or great diversion

By Mr. Keffer:

Q. It is about twenty per cent, isn't it?

A. Yes, twenty per cent.

Q. Twenty per cent higher than if you had not considered quadrant by quadrant, that is right, isn't it?

A. That is right.

Q. All right, now, you said we did so and so. Who do you mean by "we"?

A. I mean categorical we, or—

Q. What do you call it—an editorial we? Now, didn't Mr. Hammer work on that, too?

A. Up to the point where the calculation and curves were drawn, several people participated in the collection of data. Beyond that point, outside of casual discussion of the way a curve looked, or something of that sort, why, I completed the work.

Q. Did Mr. Hammer help you on it, then? Is that a correct statement?

A. In the manner described which, beyond this point that I mention, that is, the calculation and assembly and writing of the discussion, after that point it was merely casual as you would look at a curve and dismiss it.

Q. In other words, he helped you up to the point where you drew that straight line which we term a curve, is that right?

A. That is approximately the case. Not only he, but whoever participated in the compilation of the data.

Q. All right, then, you have used the pressure decline method and by taking it quadrant by quadrant you have weighted your pressure decline to a very large degree, is that correct?

A. Well, that composite factor there might be considered a weighting, I think.

Q. A weighting. All right. Now let us go on from that just a step further over to Hutchinson County Quadrant 3. Now, you stated the first thing this morning on the questioning by Mr. March that you deviated from your general plan there and take all of Hutchinson County Quadrant 3 into account, didn't you?

A. Yes.

Q. I understood you to say, Mr. Stevens, that although you didn't take all of Hutchinson County 3 into account, you did take the proportion of Canadian River's; that is, you

arrived at the Canadian River's proportion of the production by taking the production of the whole quadrant into account.

A. No. I might have given that impression and I see how that could happen because right immediately after that I turned the page and saw this compilation of additional wells which has not been in my possession for some time and bringing in those number of wells, perhaps that should be revised more correctly to read this way: That we considered the total production of the new quadrant—call it that if you will—the new designation of area that replaced the designation of area, Quadrant 3 that you see on the map.

A. All right.

A. But that total was considered having in mind the new area adopted.

Q. All right, now, that quadrant isn't outlined anywhere on this map, is it?

A. No, it isn't. It embraces generally that area covered by those wells which were read in the general south and southwest part of the quadrant.

Q. Look at Commission's Exhibit 95; Quadrant 3 of Hutchinson County is outlined there with 3 in it, isn't it?

A. Yes.

Q. All right, now, about what did you take into account in restricting that quadrant as you did for your computation?

A. I will point it out. Perhaps somebody else can point it out better than I can, but—

Q. This colored area is all Canadian River and that is all.

A. Without being exactly definite, I noted on the working papers there that that area was outlined under our '38 map which is not here, of course, but the minute designation of that area, I believe, is relatively unimportant as long as you know the wells that were involved and those were read to you this morning.

Generally speaking, I suppose, it comes down about—

Mr. March: Describe it.

The Witness: It is difficult to describe on this map, but it includes the southwestern part of Quadrant 3 as outlined

on Exhibit 95, embracing those areas shown in color and owned by the Canadian River Gas Company.

Mr. Lange: Quadrant 3 of what county?

The Witness: Hutchinson County.

By Mr. Keffer:

Q. Well, now, you used 35 wells out of Quadrant 3 in Hutchinson County. How many wells are in that quadrant, Mr. Stevens?

A. I did not look that up. I believe you wanted that—

Q. I believe I did. I believe I asked you that this morning.

A. It is a question of counting them.

Q. Sir?

A. It is a question of counting them. I can do it now if you want me to.

Q. Would it take very long? If not, you can do it during recess. Do you have it listed there?

A. By the way, the other reporter has it.

Q. We won't take the time to count them now, but there is a lot more than 35 wells, isn't there?

A. Yes.

Q. All right, now, in restricting, or taking just a limited portion of Quadrant 3, Hutchinson County, you got a lot bigger factor for Canadian River than you would have gotten for Canadian River had you considered it all, as you did on the other quadrants, didn't you?

A. Yes, but you had a lesser total amount of gas to multiply that factor by.

Q. Yes, I know, but as a matter of fact, as you have computed in here, you show Canadian River somewhere around eleven per cent of the gas produced from the quadrant as you limited it or restricted it?

A. Yes, sir.

Q. Whereas, if you had not restricted it, Canadian River would have had something like one per cent or maybe a little better?

A. One per cent of a great deal larger number, yes.

Q. Yes. Do you have any idea which is the greater figure—11 per cent of the smaller number or one per cent of the larger number?

A. No, I don't, and that is unimportant for the reason that the area considered gave a good curve, one that could be logically drawn through points and whatever grouping was determined, whether this identical one is described or some sligtly smaller or larger, if you had obtained a good curve through those points your answer would be equally valid.

Q. All right, now, you stated in answer to Mr. March's question this morning that you cut out the southwestern corner of that for the reason that that is a pretty long quadrant and all of Canadian River's wells were down in the southwestern corner, isn't that the reason you gave?

A. Well, that is probably the principal reason that I would recall at the present time.

Q. Now, didn't you have a much better reason than that, Mr. Stevens, that you didn't give?

A. As I remember, we tried the total quadrant and it didn't result in nearly as good a curve and I believe that that was one of the reasons also suggested for restricting it. It became evident that restricting it to a smaller part of the quadrant might give a better curve for projection and we found that it did as a matter of fact, and used that, which is entirely—

Q. Now, as a matter of fact, isn't the only reason you have for restricting it and not including the whole, is the fact that this method of yours wouldn't work on it at all if you included the whole?

A. You overlooked, I think—

Q. Just answer my question yes or no.

A. Read that.

(The question referred to was read by the reporter, as set forth above.)

The Witness: The fact is that it worked far more satisfactorily with the collection of data on that basis and that in itself is sufficiently good reason.

By Mr. Keffer:

Q. I see; you were looking for an answer, is that your answer?

A. We were looking for a proper lineup of points considering sufficient area and that is justified in any of this

kind of work and there is a further point which should be mentioned in explanation of this, that—to quote your previous illustration, if the Canadian River Gas Company's production represented a very very small percentage of the whole, say one per cent or less, it is obviously an advantage to reduce the area to a size where Canadian River occupied or produced a relatively larger per cent of the whole. That is not necessarily a weakness in method. It is simply a better presentation of facts because, after all, we haven't anything else in here but facts and that rearrangement to a smaller area, as I say, and as I recall from the figures, gave a better curve and hence an equally valid answer.

Q. What kind of a curve did you get when you first plotted it on the whole quadrant, Mr. Stevens?

A. I don't remember that. It could be easily found out. The data is in the working papers there.

Q. Didn't you have a gradually ascending curve instead of a descending curve?

A. It might well have been, I don't recall.

Q. What would give you an ascending curve on that?

A. An ascending curve would be caused by a—well, simply by a lack of decline in pressure against accumulated production.

Q. That's right. What would cause a lack of decline in pressure?

A. A lack of decline in pressure as it would appear on the paper would result from production in a very permeable area, perhaps, which would—and draining a large area through widespread wells, which would serve to give a lower—would serve to give a larger area—a larger production per pound. That would serve to flatten or even incline the production pressure curve.

Q. Well, now, you have given two things; one is a highly permeable area and the other I believe you stated was a small decline per pound production for that reason. Really, after all, it gets back to one reason, doesn't it—a highly permeable area?

A. Possibly that, with the assumption that the wells are fairly widespread or widely spaced.

Q. Oh, yes, I believe you did bring in the wide spacing of wells. Do you know how the wells are spaced in that area?

A. I haven't looked—I haven't considered that. This area was simply for the purpose of getting a better curve and outside of that we did not investigate details of that kind.

Q. Now, as a matter of fact, Mr. Stevens, isn't it true that you have more wells per acre in Quadrant 3, Hutchinson County, than any other single quadrant that you considered?

A. I don't know about that.

Q. Well, don't you care to hazard a guess about it?

A. No.

Q. All right.

A. If it is true, why, that is—

Q. All right. Now, do you have your work sheets there?

A. The reporter has them.

Q. Now look over that quadrant and see what we find there.

Mr. Lange: Here they are.

(The documents referred to were passed to the witness.)

The Trial Examiner: With respect to wells now, Mr. Keffer?

Mr. Keffer: No, with respect to pressures.

Q. I believe your work sheets, you said, didn't show the wells. I believe it does, too.

A. Yes, I show wells.

Q. Well, go on to pressures. That's what I had in mind. He is going to check the wells during recess, Mr. Examiner. That is all right with me.

You have the pressures shown there?

A. Yes.

Q. All right, in 1935 the quadrant pressure was 247 pounds, wasn't it, the total quadrant?

A. I don't think that—what did you say that was?

Q. 247 pounds, the total quadrant.

A. Well, now—

Mr. Lange: Speaking of the—

The Witness: The quadrant as I have it here—

By Mr. Keffer:

Q. I know, but I am talking about the quadrant before you changed it.

Mr. Lange: Referring to well head pressure, Mr. Keffer?

Mr. Keffer: Yes, that is all the well head pressure.

The Witness: 247, yes, is shown here.

By Mr. Keffer:

Q. All right, the pressure in 1936 was 253, wasn't it?
A. 246, I have it here.
Q. 246 in 1936. All right, what was it in 1937?
A. 253.
Q. What was it in 1938?
A. 253.
Q. 253—what was it in 1939?
A. 250.
Q. All right. You had a bigger pressure in 1939 than you had four years earlier in 1935, didn't you, a higher pressure?
A. Yes.

* * * * *

Stevens further testified on redirect examination (Vol. 63, pp. 9041-9063) as follows:

Q. Mr. Stevens, which one of these methods do you prefer for depleting the wells over the life of the wells or the life of the leases?

Mr. Spencer: Mr. Examiner, let us have him qualify the witness first. When I left him he wasn't qualified.

Mr. March: I asked him which one he *prefered* and that is all that is necessary for him to answer, if he has an opinion.

The Trial Examiner: I believe he just stated in response to cross examination, Mr. March, that he had made no study of the property depreciation and depletion other than that this system he proposes would be the logical method to use.

Mr. March: I want to know why he thinks it is the logical method.

The Trial Examiner: Is that what you want to know?

Mr. March: Yes.

The Trial Examiner: All right.

By Mr. March:

Q. Which one of the methods do you prefer and why?

A. Personally, I prefer this one described here as far as preference has any significance. Of course, it seemed that it was the logical one because it was tied in intimately with the life of the well or the use of the well—is tied in logically with the period of use and that is really the fundamental and probably the only basis of preference that the depletion is tied in with, the amount of gas that is going to be depleted. That seemed the very logical thing to me and that is probably the only and main reason for the preference.

Q. Your position is that you are depleting wells and that you should have the depletion period over the life of the wells?

A. Which is the history of the recoverable reserves, which is the period of producing from the recoverable reserves of the period in question. That is stating the same thing I believe.

Q. In other words, the leases aren't going to last longer than the wells?

Mr. Spencer: Mr. March, quit testifying. There is nothing in the record to substantiate that.

The Trial Examiner: Mr. March, I think you can reframe your question. I think that question you asked is wholly improper.

Mr. March: All right, sir.

Q. In your exhibit here, Mr. Stevens, do you state in effect that you can recover all of the gas from present wells under these leases?

A. If I understood your question correctly, the title of the exhibit describes it, it being "The estimate of recoverable gas reserves, present wells," and that reserve not being synonymous with total reserves to be recovered under leases, the difference between the two being recoverable by additional wells.

In short, to recover the reserve under leases, it will be necessary to drill more wells.

Q. Are you through?

A. Yes.

Q. In your opinion can you get all of the gas out from under these leases by the present wells?

A. Not on the basis of the production record to date and not on the basis of this study, which is the production versus pressure records.

Q. Are you attempting here in any way in this exhibit to give an estimate of reserves under leases?

A. No.

Q. Would it be true to state—strike that.

If your were calculating the reserves under the acreage of Canadian River or the reserves in the quadrants in which Canadian River acreage is contained, would you do it by this method?

A. What—

Q. By this method, I mean the method employed to calculate the reserves which these present wells can get out of the ground.

A. You mean if I were calculating the reserves under leases?

Q. That is right.

A. No, I wouldn't use this method.

Q. Why not?

A. Well, for the reason that the effect of weighting pressure against acreage establishes a basis upon which reserves under leases can better be calculated than does this method. While they are in general principle an expression of the utilization of the pressure decline method, yet the method used under that principle differs from that used by Mr. Hammer in the calculation of reserves under leases.

Q. If you wanted to get all of the gas from under these leases, would you have to drill more wells?

A. On the basis of this study, yes. Putting aside the purely theoretical consideration in indefinite time a given well will drain more than in any finite time, naturally, and the conditions of production are different as indicated by the production record constitutng the method here, and it will be necessary to drill some more wells to recover all of the Canadian River gas.

Q. Do you believe—strike that.

Would you be willing to testify for the record here that the Canadian River Gas Company has only two billion, two

hundred fifty-eight million, seven hundred eighty-nine billions—wait a minute. Is that two billion?—it is two trillion, isn't it—pardon me.

A. It depends upon whether you are going to call it Mcf. or not.

Q. 2,258.789 billions.

A. What are you referring to, Mr. March?

Q. I am referring to Page 3 of your Exhibit 182, where you give there the total recoverable reserve, December 31, 1939, including production for August 1, 1939 to December 31, 1939 from the present wells.

A. You are referring to the figure 2,238.849 billions?

Q. That's right.

A. Yes. In fact, I have so testified.

Q. You testified that that is all the reserves Canadian River has?

A. I'm afraid I did, and I'm sorry.

Q. I will ask you the question again. In your opinion, does the Canadian River Gas Company just have reserves under its leases amounting to over two trillion as you have the figure here recorded on Page 3?

A. That is not the reserve under leases. They have more than that under leases. This is the figure on reserves under wells, and the reserves under leases has been given in a previous exhibit.

Q. Is it your intention, either impliedly or otherwise, to give here an estimate of the remaining reserves under Canadian River leases?

A. No, it is not.

Q. And as I understand you, if you were computing the reserves under leases you would have employed a method employed by Mr. Hammer?

A. Yes.

Q. And you would not employ the method employed here?

A. That is right.

Q. As I understand your exhibit here, 182, it is an exhibit which involves the study of the action of wells and wells alone?

A. As expressed in your production and pressures, yes.

Q. It has nothing whatsoever to do with acreage?

A. That is right.

Q. We have had considerable discussion here as to why

you employed quadrants, why you used the same quadrants that Mr. Hammer used in his exhibit. The question was asked you as to what your estimate of reserves which could be recovered by the present wells would be if you had disregarded the quadrants, and I believe there was some statement made here that it was twenty per cent—it would be twenty per cent lower. Now, have you made a calculation to determine exactly what per cent lower it would be?

A. That would be 16.455 per cent below the figures shown for 7-31-39. That was the basis upon which the computation was based, of course.

Q. And why didn't you ignore the quadrants?

A. For the general reason that it was desirable to split up the area in some manner. It could probably have been done in some other form of areal distribution than the quadrants shown. The only reason for taking the quadrants as shown was more one of consistency than anything else, but that they should be broken up into some areas—quadrants in this case is preferable for the reason that analysis of the characteristics of component parts can be more closely studied and the diverse effects in those areas be more accurately charted and weighted into a whole to arrive at, by summation, a result which result is I believe superior to a similar result arrived at by a wholesale consideration of the total area involved.

Q. Is it correct to state that probably the principal reason was that you thought it necessary to have wells in adjacent territory grouped together and studied separately and then relate them to the whole?

A. To relate them to the whole by summation, yes.

Q. Now, I believe it was brought out that you followed exactly the quadrants as contained in Mr. Hammer's exhibit with the exception of Hutchinson 3?

A. Yes.

Q. And I believe it was likewise brought out that the only reason that you did that is because there were no Canadian River wells in the northern part of that quadrant at all?

Mr. Keffer: Now, if the Examiner please, that is not the record, Mr. March. That is not what the record shows. That is what you said.

Mr. March: I will ask him that a different way if Mr. Keffer insists.

Q. Will you explain for the record just exactly why you did not use all of Hutchinson County, Quadrant 3, as Mr. Hammer had delineated it on his map?

A. We started to use it that way consistent with all the others. The nature of the pressures of the wells of other companies in the north—general northern part of the quadrant is such that when projected against accumulated production it gave a very erratic curve, in fact, it was almost an ascending curve if not actually so.

Mr. Keffer: Almost what kind?

The Witness: Ascending. That suggested, looking at the quadrant with respect to distribution of Canadian River acreage and noting that it was entirely in the southwest corner—the suggestion was apparent that perhaps a treatment of that part of the quadrant directly related and adjacent to Canadian River acreage might result in a better alignment of data and constitute a better basis for estimation of Canadian River's recoverable reserves. That proved to be the case and it was simply adopted for those reasons.

By Mr. March:

Q. Mr. Stevens, are there any Canadian River wells at all in the northern part of Hutchinson Quadrant 3?

A. Not that I recall. I am quite sure that is the case. If there had been it would have—well, Exhibit 95 will show that very plainly I think. Here is Canadian River acreage over here (indicating).

Q. Are there any Canadian River wells in the northern part of Hutchinson 3?

A. According to this exhibit there are not, nor do our records indicate any.

Q. According to this exhibit, where do you find the Canadian River acreage?

A. In the southwest part of the quadrant.

Q. Solely in the southwest part of the quadrant?

A. Yes.

Q. Now, Mr. Stevens, if there had been Canadian River wells up here in the northern part of the quadrant, you could not have disregarded the northern part of the quadrant, could you?

A. No, you could not have.

Q. Oh, yes, there was some further discussion about

that, so therefore the principal reason was you did not use the northern part and did not deem it necessary because no Canadian River wells were up there, is that not correct?

Mr. Spencer: Now, there he goes again—"the principal reason." Let the witness state what the principal reason was.

The Witness: Those are the principal reasons and those are valid reasons I think.

By Mr. March:

Q. Oh, yes, there was some discussion—I believe you admitted that had you used all of Hutchinson 3 in spite of the fact that there were no Canadian River wells in the northern part of it that you would have got a gradually ascending curve?

A. As I recall it was of that nature almost. It certainly wasn't a definitely descending curve in the sense that these others are.

Q. Mr. Stevens, in any of these other quadrants using the data for 1937, 1938 and 1939, do you have a similar situation?

A. Not with respect to the values for those three years, no.

Q. You don't have any quadrant—do you have any quadrant at all which was comparable to Hutchinson Quadrant 3?

A. No, there were none.

Q. Now, Mr. Stevens, there has been a great deal of discussion about these curves that you have drawn here as reflected in Exhibit 182. Now, I want to direct your attention to the individual quadrant curves which you have constructed. There was some implication that in these individual curves that you arrived at your answer first and then drew your line. Is that correct?

A. There might have been. I believe there was, partially, at least.

Q. Now, I direct your attention to Quadrant 4, Carson County, which is the first quadrant curve. Now, I will ask you, did you determine mathematically the points there before you drew your curve?

A. In the sense of arithmetic, yes, and that the pressures were averaged and the production was accumulated.

Q. You plotted to arrive at those individual points there your production against your pressures?

A. That is right.

Q. And it was after that that you drew your line?

A. That is right.

Q. Your curve?

A. Yes.

Q. Now, I direct your attention to that curve and ask you whether or not it would be possible for you to draw that curve any other way without increasing your estimate, giving consideration to '37, '38 and '39.

A. It would not have been possible to draw it any other way without increasing the estimate of reserves, for the reason that had we drawn it any other way to more completely employ '37 than we have, the result would have been a curve at a gentler slope which would have the effect of increasing the reserves.

Q. Then it would have been impossible for you to draw this line any other way, giving proper consideration to '38, '37 and '39 without increasing your estimate?

A. That is true.

Q. Now, Mr. Stevens, I want you to go through—glance through every single one of these quadrants here—Quadrant curves, and tell me which, if any, you could have drawn differently, giving consideration to '37, '38 and '39, without increasing your estimate of reserves.

A. The next one is Hartley County Quadrant 1. If any more consideration had been given to 1938, it would of course have increased the estimate of reserves for that quadrant. However, if we accept the premise that '38 is obviously low for some reason, then '37 should be given more weight and '38 ignored. The result in this case would have been a very slight decrease of the estimate of reserves.

However, that lineup of points there is probably, and in general, considering average opinion, I believe the only one where any logical change would decrease rather than increase the estimate of reserves.

Q. You just check the others to play safe.

A. And the next one, Hutchinson 3, described as being in the southwest part of the area, Hutchinson 3 marked on Exhibit 95, we have a lineup of points there in which 1936 does not appear to be had. However, it wasn't given major weight, but if 1938 were given any more weight than is

given there the result would have been an elevation in the reserves and an increase in the estimate of reserves.

Mr. Keffer: How about 1939, if you had drawn it right through the center of it?

Mr. March: I am asking the question, Mr. Keffer.

The Witness: That would ignore 1938, Mr. Keffer.

Mr. Keffer: How's that?

The Witness: That would ignore 1938. We are considering all three points.

Mr. March: I am asking the questions, Mr. Keffer.

Mr. Keffer: Take 1938 like it is, drawing the line through 1939.

By Mr. March:

Q. Could you have drawn this line giving *consideration* to '37, '38 and '39 any differently from what you have done without increasing your estimate of reserves?

A. No, it couldn't be done without increasing the estimate of reserves unless—

Q. That's all now. Just a moment—

Mr. Spencer: Mr. Examiner, can't the witness finish his answer? Must I protect him?

By Mr. March:

Q. Now, Mr. Stevens, could you have drawn that line any other way, any lower, giving a lower estimate of reserves and still touch '38?

A. No, you could not. That was the point I was about to mention.

Q. Now we'll go to the next one and check that one.

A. Moore County Quadrant 1.

Q. Right.

A. That, as I see it, is the only way that could be drawn without ignoring 1937, and the only way it could be drawn to show a lesser reserve would be to ignore '37.

Q. I will ask you this question: Could that line have been drawn any other way, touching all three of those, touching '37, '38 and '39 without increasing your estimate?

A. No, under those conditions it could not have.

Q. All right. I will ask you the same question with regard to Quadrant 2, Moore County.

A. That is right, also with respect to Moore County, Quadrant 2.

Q. In that case, Mr. Stevens, if you had gotten closer to the point of '37 than you did, would that have increased your estimate of reserves?

A. That is right, it would have.

Q. The next one, Moore County, Quadrant 3. Now, Mr. Stevens, in that case you split 1938 and 1939 points right down the middle. Now, if you had gotten any closer to the 1937 point, would that have increased your estimate of reserves?

A. It would have.

Q. Potter County, Quadrant 1, could you have drawn that line, touching each of the three points 1937, '38 and '39 without increasing your estimate of reserves?

Mr. Keffer: Now, just there, Mr. Examiner. Mr. March made that statement many times and made it again here. I have let it go, but it is so erroneous it distorts the record and I feel that some observation and objection should be made at this time.

He talks about "touching the point '38," which the line does not do at all, which he can tell by looking at it.

Mr. March: If you would like my language a little better and a little more concise and complete, I will state it this way:

Q. Mr. Stevens, could you have drawn this line any closer to the 1938 point without increasing your estimate of reserves?

A. Well, you could draw it through the center of '38 and '39 and it would decrease the amount of reserves.

Q. I am talking about the three years.

A. But giving equal weight in the situation to '37, you could not do that.

Q. But now since you brought that up, Mr. Stevens, I want to ask you this question: Would you have attempted anything like this if you just had the data for the two-year period, '38 and '39, and had no other data?

A. In general one would not draw a curve on two yearly

points unless he had to. In a couple cases here we have split '38 and '39 points, but even so, '37 has played some reasonable relation, but in the event of having all of these nine quadrants based on only two points, it is quite unlikely that the reserves would have been drawn in this manner and using this same group of data.

Q. Your statement is, as I understand it, that if you had just had the data for a two-year period, '38 and '39, you probably would have never made this study in the first place because it would be inadequate for such a study like this.

A. That is true, yes.

Q. And in every case you drew a line here, you did give some consideration at least to the three-year period?

A. Yes, even though, as stated, the curve was drawn through '38 and '39, that represents about two cases, I believe.

Q. All right, let's go to the next one, Potter County, Quadrant 2. Now, I will ask you—there is a quadrant in which you split the points of '38 and '39 and you missed 1937. Now, I will ask you this: If you had given any more consideration to 1937 than you did give, what would have been the effect on increasing or decreasing your estimate of reserves?

A. It would have increased the estimate.

Mr. Spencer: There is a place, Mr. March, where you used two points.

Mr. March: The witness has testified he always gave some consideration to the three points, although in this particular case here it pierces right through the center of '38 and '39.

Mr. Spencer: Right.

Mr. March: The witness also testified that he wouldn't even have prepared this exhibit if he just had data for two years.

Q. Now, the next one, Potter County, Quadrant 3. Now, there is a case again where you ply right through the middle of '38 and '39, and you miss your 1937, it is below the line. Now, I will ask you this question: If you had given

any more consideration to 1937, what would have been the effect thereof?

A. It would have increased the estimate for that quadrant.

Q. Now we turn to our composite, Mr. Stevens. On your composite, how did you arrive at your 1935 point?

A. '35?

Q. How did you arrive at your '35 point?

A. The '35 point at zero production is simply the average production for 1935.

Q. Is the 1935 point the composite of all the 1935 points upon your individual quadrants?

A. Yes, in that it is a summation of all the wells in all the quadrants.

Q. Now, how did you arrive at your 1936 point?

A. The summation of all well pressures in 1936 reduced to an average, plotted against the total quadrants—production for 1936.

Q. It is your—is your 1936 the composite of all your points in the preceding quadrants?

A. Yes.

Q. How did you arrive at your 1937 point?

A. In the same manner.

Q. And your 1938 point?

A. The same manner.

Q. And your 1939 point?

A. In the same manner.

Q. Now, Mr. Stevens, I will ask you this question: Would it have been possible to have drawn this line on your composite any differently from the way you did draw it, coming any closer to all three of your points, your '37 point, your '38 point and your '39 point?

A. In general that occurs to me to be a very sensible interpretation of those points. Now, it must be remembered in the case of this total curve or composite curve that the summation of data did give us another point which is the end point at 25 pounds abandonment; so in a sense perhaps this curve should be described as being drawn not only on three points *prinarily*, but on four points since you know in that case the answer that you had to come out to.

It would have been possible to draw it backwards, as a matter of fact.

Q. Let's forget all about the answer which you had now, the answer which you had over here on the right-hand side of your page, the fourth point that you had, and I will ask you this question again: Would it have been—do you understand the question?

A. Yes, I do. As it is the line, as far as I can determine it here by eye, splits '38 and '39 equidistant—split the space equidistant between those—

Mr. Keffer: '38 and '39 equidistant?

The Witness: They are very very close to it.

Mr. March: Get your slide rule on that. Have you got your slide rule on that—I mean your triangle?

Mr. Keffer: He has that to check that distance as between '38 and '39—

Mr. March: You can cross examine the witness when we get through, Mr. Keffer.

Mr. Keffer: Well, that will be some time, and I don't want an obviously false statement to go in the record.

The Witness: Regardless of whether you consider it a serious error in judgment, it represents a very reasonably drawn line and with regard to the statement that four or five engineers would have all drawn a different line, it is, of course, possible for fifty different engineers to draw fifty different lines as may be dictated by considerations which may be from prejudice or diverse judgment, whichever applies, but there is very very few different ways in which this line could be possibly drawn and drawn sensibly.

Mr. March: Yes.

Q. Then is your statement here—is my statement correct, after you observe this, could this line have been drawn any differently, giving more consideration than you have given to the points '37, '38 and '39—giving consideration to all three points?

A. To give more consideration to '38 and '39 would have given a less reserve, but it would have resulted in giving less and less weight than '37 appears to deserve.

Q. Yes, but if you had—

A. So assuming that with respect to '37 which has not

been ignored in previous cases—there is no reason why it should be ignored here, and I simply regard it as a very reasonably drawn line.

Mr. Spencer: Mr. Examiner, perhaps I misinterpreted the witness' testimony. It sounds to me as if he were saying that he had exercised some judgment in drawing the line. As I recall his testimony on cross examination he had a point which he had to reach, the course of the line backwards was determined before he started—

The Witness: It was determined in a sense, yes.

Mr. March: He can explain that.

Mr. Spencer: I just didn't want the impression here—

Mr. March: Go ahead, Mr. Stevens.

Mr. Spencer: If the record is clear, that is fine.

The Trial Examiner: I think he did, Mr. Spencer.

Mr. Spencer: Pardon me for interrupting.

The Trial Examiner: As a matter of fact, I think he reiterated his statement on cross examination.

By Mr. March:

Q. Now, Mr. Stevens, I want to ask you this question: If you had given—what would have been the effect of the situation if you had given any more consideration to 1937 than you did?

A. Well, you would be getting farther away from 1938. You could do that in two ways. You could move the line in a general southward direction parallel to itself perhaps, or you could have swung it about the point it now occupies near 1939.

Q. Well, if you had moved 1937, the line any closer to 1937—do you see what I mean?

A. Yes, it would have gone farther from 1938 and given less weight to 1938.

Q. Well, what would have been the effect of that? would it have increased or decreased the estimate?

A. It would have increased the estimate.

Q. Can you tell me how you could have drawn that line any differently from what you did, giving consideration to

all three points, without increasing your estimate—in fact, all three points?

A. Yes, I understand. I don't see how it could be changed without any justification whatever, having in mind the effect of 1937; that is, assuming that we did not know what the total was and were drawing this entirely with respect to the points. However, this curve is simply a summation of the data. It represents the summation of the data from which the other curves were drawn individually.

Q. As I understand it, before you started drawing this curve you had something that you didn't have when you started drawing these other quadrant curves?

A. That is correct.

Q. You had the answer, is that correct?

A. That is right.

Q. You had the slope of the curve?

A. Yes.

Q. But if you had not had that answer, if you had not had that slope—I mean indicated, and you had just had these points up here; then is there any possible way in which you could have drawn that line, other than what you did, giving consideration to '37, '38 and '39, without increasing your estimate?

A. No reasonable way that it could be done without doing so.

The witness further testified on recross examination (Vol. 64, pp. 9104-9176) as follows:

Q. Now, you have agreed with me, I take it, then, that if the present wells in Quadrant 1, Potter County, will produce all the gas in that quadrant, then the drilling of additional wells certainly would not increase recoverable reserves except to a very very minor extent possibly. That is correct, based upon the assumption.

A. You aren't asking me to affirm the assumption, are you?

Q. No, not the assumption, the result based upon that assumption, that's all.

A. Well, the result based on that assumption is, as you say, but I would like to add that it is an erroneous assumption, that's all.

Q. Well, it may be. I am not admitting that it is er-

roneous, mind you. Now, will you tell me what part of Quadrant 1, Potter County, that the present wells will not drain—will not produce all the gas now underlying that quadrant? That's my next question.

A. That question—

Q. Just answer my question.

A. It will be as stated before, I believe, that the amount of gas it won't drain would be in the area least accessible or available through action of permeability to the wells.

Q. All right, point it out on the map. I want to know where those areas are.

A. It would be in the areas of highest pressure, without even looking at the map, as compared with the lower pressures wherever they are located.

Q. All right, you are going to assume at the end of that period, whenever you are down to 25 pounds, that the southernmost wells of that area which are now in the highest portion of the area, when they are down to 25 pounds, certainly everything north of them is going to be down to 25 pounds.

A. The central point—

Q. Just answer that question. Isn't that a fact?

A. That the area north of it—

Q. Yes, is going to be down to 25 pounds, too, because it is already much lower, or some lower than those southernmost wells.

A. That is a reasonable assumption, but there is still the fact that some other areas will be over 25, and whatever they are—

Q. What other areas?

A. Whatever they are is unimportant. It is the fact that they will be there and their specific location is really extraneous to this except in principle.

Q. You say they will be there. That's the very thing I want to find out. How do you know they will be there? Give me your reasons.

A. You have agreed on many occasions that areas away from the well will be at higher pressure.

Q. That's right, but how much higher?

A. I stated that that is indeterminate.

Q. You know it wouldn't be very much, don't you?

A. You do not even know that, but as to the degree, that has been stated to be indeterminate.

Q Would it be as much as 10 per cent of the total?

A. It is indeterminate.

Q. How's that.

A. You were talking about pressure a minute ago.

Q. That pressure is still what we are talking about. You say the pressures would be higher away from the well, didn't you?

A. Yes.

Q. And I have agreed with you that that is a fact.

A. Yes, and I simply decline to hazard a guess as to how much it would be.

Q. I just asked you if it would be as much as 10 per cent.

A. If you can't say in pounds, you can't say in per cent.

Q. Do you have any idea how much?

A. No, no one does.

Q. Would you say 10 per cent would be too high or too (illegible).

A. I don't say anything about it.

Q. You just don't know?

A. I just don't care to hazard a guess. It is just impossible.

Q. All right, let's get back and we'll leave this for a moment. Now, you follow me here. You said a while ago your gas would remain in areas of higher pressure when you get down to 25 pounds.

A. That is a general statement of fact.

Q. It is a correct statement, isn't it?

A. Yes.

Q. Now, the southernmost wells in that quadrant now are some 2½ miles from the south boundary line of the quadrant, are they not?

A. The wells.

Q. Yes.

A. Yes.

Q. All right, now, those wells are in the highest producing area of the quadrant where wells are located aren't they; that is, those wells have higher pressures than other wells in the quadrant?

A. Well, as a matter of pressure, yes. You are tying in production with—

Q. No, I am talking about pressure.

A. All right.

Q. The pressures of these southernmost wells are the highest pressured wells in the quadrant.

A. Yes, sir.

Q. Now, when those wells are down to 25 pounds, every well north of those is going to be down to 25 pounds, aren't they?

A. Well, the contours run less as we go north.

Q. They do?

A. They do. You say they would be less than 25 pounds?

Q. No, would also be 25 pounds—at least 25 pounds.

A. That is a reasonable assumption.

Q. It is an unavoidable conclusion, isn't it?

A. Assuming the pattern remains the same or approximately the same.

Q. All right, then, we have got it pretty well established that the pattern remains the same; that everything north of the present producing wells which are 2½ miles from the southernmost boundary, would be 25 pounds. All right, and we aren't drilling any more wells either.

Now, we established a while ago that if the pattern remains the same that when those wells are 25 pounds, that down at the edge of the field it would not be any more than —that is, in the area which is now shown as virgin—well, wait a minute. Strike all that.

Those wells are in the 410-pound isobar band, aren't they—that is, from 410 to 420? Those are the ones you said a while ago—the one over here (indicating).

A. Here is the 400, the 410 and 420 and 430.

Q. Then those southernmost wells have a pressure now of about 405 pounds as shown by the map, is that right?

A. I believe that is the case.

Q. "I think"?

A. All right, 405.

Q. 405 pounds, is that what you said?

A. Yes.

Q. All right, now, and you show for a portion of that

area southwest—*southward* at least, a pressure now of 430 pounds, don't you?

A. Yes.

Q. The difference is 25 pounds, isn't it?

A. Yes.

Q. So when that well gets down—the well we are referring to which is the southernmost well in that quadrant—gets down to 400—I mean, gets down to 25 pounds, then the highest pressure on the southern side of your quadrant would be 50 pounds if the pattern remains the same?

A. That is indicated, and it also assumes that that isobar spacing is proportional—is truly proportional in the area immediate to the well.

Q. That's right, and the pattern is going to remain pretty much the same. All right, 50 pounds would be the very highest you would have south of that well, wouldn't it?

A. Disregarding those other factors, yes.

Q. And it would grade down by isobar line, by isobar line, down to 25 pounds; so your average would be a lot less than 50, wouldn't it, south of that line, to the southern extremity of the production; that is right, isn't it?

A. Your average, yes.

Q. All right, now, we have already agreed that everything north of that well will be down to 25 pounds because it is already much lower or gradually lower than that well to the north of it. That is correct, isn't it?

A. Yes, but between successive wells there will also be higher pressure areas than 25 pounds; so the very southernmost area isn't the only one to be considered.

Q. Now, when we have produced those wells that are in that quadrant now down to 25 pounds; then on the admissions you have just made, there is going to be practically no gas or very little gas left in that quadrant above your 25-pound abandonment pressure. Now, doesn't that naturally result?

A. Well, as you say, there is very little more.

Q. That's right.

A. It would be the amount of gas resulting from the increased pressures, whatever that amount of gas was.

Q. All right, we have demonstrated here I think that the highest pressure we would have would be 50 pounds.

A. And whether it is little or large depends upon that

degree of difference, and as indicated by the study, it is the difference between the reserves of the two estimates, one under wells and the other under leases.

Q. Well, now, as a matter of fact, from the very thing that we have just been talking about, Mr. Stevens, your estimate of recoverable reserves under Quadrant 1, Potter County, becomes and is an estimate of reserves under the leases in Quadrant 1, Potter County?

A. No, I have never maintained that or admitted it.

Q. I know you haven't admitted it, but the thing I am talking about, the figure which you got as being the gas recoverable from the wells is also the figure of the gas recoverable from the quadrant, under the leases.

A. Under the present wells as they are distributed only.

Q. Yes, sir, and all this we have been going through, we haven't drilled any more wells at all.

A. Well, you are presuming that all you ever want to recover is recoverable by these present wells and that is merely a matter of definition. Mr. Hammer's definition of leases presumes that you do recover the gas there is in there to recover.

Q. But Mr. Hammer's estimate may be wrong. Now, here is what we are getting to. Now, it is admitted—now, let's don't go back over it again—that whenever the well in that quadrant is down to 25 pounds that the highest pressure you will have in the quadrant down in the extreme southwest corner of it will be 50 pounds if the pattern remains the same.

A. And in other places between wells.

Q. All right, other places between wells it will be what?

A. That covers all the quadrant.

Q. I know, it will be what between wells?

A. That again is indeterminate, but you are going on the premise, Mr. Keffer, if I may say so, that if you had one well there that when you got it down to 25 pounds, that would be the reserve for the leases.

Q. It is the reserve for the leases if it drains the whole quadrant.

A. Well, but it won't.

Q. I know you said that a hundred times, but you have never given very convincing reasons to me why the wells in that quadrant today won't drain that quadrant, Mr. Stevens.

If you could answer me that question, we could cut all these questions that I have asked you this morning, if you would answer that one question.

A. These are tied in with practical things, finite time, the way you do things, hypothetical assumptions of one quadrant to the field. On your assumption you are about to make a conclusion or certainly imply that one well—all the gas that you could get out of that one well down to 25 pounds is the reserve of the field which is an absurdity on the face of it.

Q. I didn't make any assumption, but in fear that you may think I have, let's go back to Quadrant 1 we have been talking about. The wells are pretty well distributed over the quadrant, aren't they, and there is more than one well, isn't there?

A. Yes, and there are spaces between wells.

Q. How many wells in that quadrant? Look and see—39—there may be more now.

A. Well, that is approximately correct. There were 24 wells in the quadrant in which pressures were available.

Q. That's right, 24, and pretty well distributed over the quadrant, isn't that right?

A. Yes—well, I think so.

Q. Well, all right, take a look at it, Quadrant 1, Potter County.

A. The line across the northeast quarter—or the northwest quarter of the quadrant shows three wells and I don't see any northwest of that so that area is relatively—yes, I say the northwest quarter and the line running diagonally—yes, that is one of the three, but nevertheless, from the looks of it there are many locations if you consider the section as a drilling unit.

Q. All right.

A. There are many locations yet to be drilled in Potter 1.

Q. All right, now, answer my question. I don't know—you don't even consider a section a drilling unit, do you?

A. Well, they were on there for the purpose of comparison.

Q. How do you mean they were on there?

A. Wells were located in the center of sections, weren't they?

Q. I know, you've got to put it somewhere. The fact

that a well is located in the center of a section doesn't mean the section is a drilling unit, does it?

A. It doesn't, but the fact remains that there are considerably sized areas in Potter County that could logically drilled.

Q. All right, let's get away from sections as drilling units. The 24 wells in that quadrant are fairly evenly distributed over the quadrant except for the two or three miles on the south side of it.

A. South side and the northwest corner.

Q. Northwest corner, but you have wells in the northwest corner, haven't you?

A. I refer to the northwest corner as being the diagonal west half of the northwest quarter of the quadrant.

Q. Well, that would be about the northwest quarter, wouldn't it—half of a half is a quarter, isn't it?

A. That same area that is on that diagonal.

Q. Well, that might be about a quarter. That's close enough, anyway. All right. Now, I am going to apologize to everybody for staying on this so long.

You have far more wells per acre in Quadrant 1, Potter County, than you have in Quadrant 3, Potter County, haven't you, per acre?

A. I think that is true, there being only nine wells indicated here on Potter 3, that is right.

Q. Now, your nine wells in Quadrant 3, Potter County, by your own admission, is going to produce all the gas there and even a little more. That's right, isn't it?

A. Well, if you assume that you are comparing the reserves under leases and the reserves under wells as stated by the two exhibits.

Q. Now, I am getting away—yes, I am taking the reserves under leases as distinguished from the reserves under wells as you make the distinction.

A. Yes, we show those produce a little less than a fifth.

Q. That's right. You had over there a well that is in Quadrant 3—a well almost every 4,000 acres, didn't you?

A. I believe that was determined the other day.

Q. All right, now, what is your average well spacing in Quadrant 1, Potter County? Let's just compare them. Where are your acres?

A. I don't have the acres on here.

Q. Somebody give me the acres. It's in Mr. Hammer's exhibit. Do you know what it is?

A. No, I don't offhand.

Q. All right, look at Mr. Hammer's exhibit. Mr. Hammer's exhibit shows the acreage in that quadrant to be 57,588 acres, and you show 24 wells. That's right, isn't it?

A. I show 24 wells on which pressures were available to determine the pressures.

Q. There may be a few more wells now. I think there is, but we'll take 24 wells which you show. You have a little better than 2,000 acres to the well, haven't you—less than 2500 or about 2500?

A. 2400.

Q. All right, now, that's a lot closer spacing than you have over in Quadrant 3, Potter County, isn't it?

A. Yes, but two quadrants can't always be compared on spacing alone.

Q. That may be quite true, but the fact, nevertheless, remains you have a closer spacing in Quadrant 1, Potter County, than you do in Quadrant 3, Potter County?

A. That is right.

Q. All right, you say that the present spacing in Quadrant 3, Potter County, will produce all of the gas that Mr. Hammer shows under the leases and some over, don't you?

A. In Potter 3?

Q. That's right.

A. Yes, about a fifth more.

Q. How's that?

A. About one-fifth more.

Q. Yes, all right; then assuming other things are the same, it would be a very reasonable assumption to assume that a closer spacing in Quadrant 1, Potter County, would also produce all of the gas in that quadrant, wouldn't you?

A. If the comparison were based entirely on that criteria, that would be so, but your production doesn't show that.

Q. How do you mean "production doesn't show it"?

A. Production versus pressure, arriving at a recoverable reserve, and that recovery being compared to the reserve under the leases which—

Q. Now, you are going back to your answer for the pur-

pose of the comparison. Now, that's what I am objecting to. Maybe your answer is wrong. That is what I am objecting to. Let's don't go back and assume the answer and then check into it to see if you are right or wrong. We are trying to find the answer in this calculation.

A. The answer is indicated, as the answer shows, on the basis of production history. It is the answer and it isn't getting away from the fact that that is the answer and if the comparison is such as you say, that is just all there is to it.

Q. Now, you say—what is the answer?

A. Pardon me. Let me finish.

Q. Excuse me. Go ahead.

A. And it is all supportable. In fact, we think it has been adequately shown that the reserves under leases of Mr. Hammer's study is a minimum estimate, so the fact that—

The Trial Examiner: Just strike that portion from your answer. You go on and explain, but there is no reason for an answer like that. That isn't any part of the explanation.

The Witness: I'm sorry. I apologize to everybody, but I just did want to finish it. The fact that we show a reserve recoverable under the wells to be a little bit more than reserves under leases is supportable in our opinion as indicating a minimum estimate on the part of Mr. Hammer on another method and perhaps it should be pointed out again also that in making this, quadrant confines were observed, where in the other estimate the quadrant was determined as to reserve with respect to adjacent quadrants.

By Mr. Keffer:

Q. Well, I don't know whether that answers the question or not. Frankly, I've forgotten what I asked, but I believe you did answer. I'll shortcut here, if the Examiner please.

You did answer that if everything was the same that assuming similar conditions in Quadrant 3, Potter County, and Quadrant 1, Potter County, then your wells that are now located in Quadrant 1, Potter County, will produce all the gas that is there. I think you said that.

A. Potter County 1?

Q. Yes.

A. I thought you were talking about Quadrant 3.

Q. I say, if conditions in Quadrant 3, Potter County, and Quadrant 1, Potter County, are the same; then the number of wells now in Potter County 1 will produce all the gas in that quadrant.

A. Well, Potter County 3 was the one in which we had extensive discussion.

Q. Can you answer that question directly? I thought you already answered.

A. It will produce—let's put it this way: It will produce more than indicated by Mr. Hammer's reserve, but it still may produce—but it is entirely possible due to the effect of drainage in Moore County 3, it is entirely possible that more wells will be necessary in Potter County 3, so your conclusion is not fully supportable as to the particular condition there.

Q. Well, let's go back, then, to Potter County 3. Can you say to me that you have more drainage into Potter County 3 than you have out of it, looking at your map?

A. You can't evaluate it.

Q. Then you can't say, can you?

A. I have gone only on the basis of the record, Mr. Keffer, and to do otherwise—

Q. Just answer my question. You can say whether there has been drainage into Potter County, Quadrant 3, any more than there has been out of it, can't you?

A. I have not made a study of it.

Q. You just can't say, then. Just say you can't if you can't.

A. I can't.

Q. All right. That's all I want you to say. Since you can't say that, then you can't evaluate it and you can't give that as a reason logically.

A. I am trying simply to explain something that can't be explained with specific exactness, but only in principle, and it all goes back to previous earlier statements that this study is determined on what the record shows.

Q. Well, that is production record of wells, isn't it?

A. Yes, sir.

Q. All right, now, getting back to the question I asked you a while ago, assuming conditions are the same in the

two quadrants, Potter County 1 and Potter County 3, then you have enough wells already in No. 3, Potter, to produce all the gas that is there under the leases. That is right, isn't it? It would have to be.

A. Under the manner in which those reserves were determined, you might draw that as a conclusion, but it can't be concluded that absolutely no more wells will be necessary for the reason, I believe, that I just explained.

Q. On drainage. Was that your reason?

A. It may be drainage or whatever the reasons are, it is really immaterial. It is a fact that in Quadrant 3, as you say, the well distribution is—

Q. Not as good as it is in 1.

A. The territory—the Potter Quadrant 3 is not covered as completely by wells as is Potter 1.

Q. That's right.

A. And you have stated that it has impermeable areas in it.

Q. I have stated?

A. Yes, I think you claimed that it had impermeable areas in it.

Q. I didn't know I had. I have forgotten that I had.

A. If any rate could be considered comparable, as you are trying to make it, it is a conclusion that more wells could be drilled and probably should be drilled, and in which case the recoverable reserves would still be more than what it is over Mr. Hammer's method on the way he figured it, having in mind there the two methods of figuring, he including adjacent quadrants and I including only the quadrant in question, which makes a comparison of the figures entirely improper except on the broadest considerations, Mr. Keffer, and I think that answers the whole question.

Q. It makes it more difficult. You don't mean improper, exactly?

A. Well, the degree of difficulty almost makes it improper.

Q. All right, let's go a step further and see if I can't help you. You say you have got a good reason, but you don't know what it is. Let's see if I can help you get the reason. You would appreciate that, wouldn't you?

A. If you could evaluate the differences it would be, yes.

Q. All right, let's take Potter 1. See how your isobar lines run there? Can you see from there?—to the northeastward.

A. Yes.

Q. It indicates a rather rapid movement of gas, doesn't it, out of Potter County, Quadrant 1, to the northeastward?

A. I don't think it does.

Q. Well, all right. Now, let me ask you this: Now, on your method—now, I am talking about your method—you always come back to say that the records show this, the records show this, and the records show this. Now, on your method the records which you take are the production records, aren't they?

A. Yes.

Q. Plus the rock pressures, aren't they?

A. Yes.

Q. All right, now, let me ask you this simple direct question: If you have drainage out of a quadrant, then your production records as related to your rock pressure records will show a greater decline in rock pressures than you would have had if you had not had that drainage out, won't it? Just answer that. Anybody can answer that question.

A. That is right.

Q. That is right. All right. Consequently, on the way you have figured it you would show less ultimate production from every well in a quadrant of that character, wouldn't you, necessarily so?

A. If the drainage was occurring in the degree which you assume.

Q. Well, if it was occuring in any degree it is reflected there. You have said many times it is reflected.

A. It is reflected, that is right.

Q. Yes, sir.

A. But I believe you are assuming a marked degree, aren't you?

Q. No, sir, I am assuming the degree, whatever it is, as reflected in your figures. All right, now, the answer of that reflection, or the reflection, rather, that we get is that we get a higher drop in pressure per volume of production, and consequently, the way you have figured it, each well in that quadrant would produce less gas on your figures than if there had been no drainage. Now, that's just fundamental, isn't it?

A. That is correct, in principle, but this is what the record shows.

Q. I know, I am talking about the very record that you are talking about. The record as you have recorded it shows far less production per well than in the way you have figured it over any period in Quadrant 1, Potter County, than it does in Quadrant 3, Potter County, doesn't it?

A. Oh, you are comparing Potter 1. I thought you were talking about Potter 3.

Q. No, I say, the record as you have it shows that the value of a well in Quadrant 3, Potter County, is much more than it is in Quadrant 1, Potter County?

The Trial Examiner: From the standpoint of production?

Mr. Keffer: From the standpoint of production as compared to pressure drop. In other words, your pressures drop faster with the same volume of production in Quadrant 1, Potter County, than they do in Quadrant 3, Potter County.

The Witness: Well, they are down to—yes, there is a difference of about 14 pounds.

By Mr. Keffer:

Q. All right, now, the whole point is, your wells are dropping more rapidly in Quadrant 1, Potter County, than in Quadrant 3, Potter County, when *syncronized* with the production you are getting from the respective quadrants. Now, there isn't any question about that, is there?

A. That's right, but you omit an important consideration and that is the volume of gas that may be there, Mr. Keffer.

Q. Well, now, I don't know how much gas is there. I don't want to assume the answer on these. All right, now, let's go back to another angle on that, then: Your wells, because the pressure drop in Quadrant 3, Potter County, is slight compared to the production, but when you come—and by reason of that fact you come out above Mr. Hammer?

A. You say a slight pressure drop?

Q. As compared to the production, the volume of production.

A. The production is greater—is less in Potter 3 than it is in Potter 1.

Q. I know, but you have got a lot less area to the pound drop, and I haven't checked it. I am getting way out on a limb, but the pound drop in Quadrant 3, Potter County, is less when related to production than it is in Quadrant 1, Potter County, isn't it?

A. Well, let me see.

Q. I am trying to help you solve this thing that you can't understand, and maybe it won't solve it.

A. Potter 1 has a greater area, is that right?

Q. Oh, yes, of course.

A. And you say it has a greater production per pound than does Potter 3?

Q. No, I say Potter 3 has a greater production per pound drop than does—

A. Well, I'll have to investigate that.

Q. How's that?

A. I think we ought to investigate that.

Q. All right, can we do that real quickly? Now, here is the thing I am basing it on. Now, see if I am not right. Now, you get a lot more—as you have figured it here you get a lot more production per well in Quadrant 3, Potter County, than you do in Quadrant 1, Potter, and if that is true, I can't see any other answer to it except the production drop.

A. I think we are confusing—we are talking about two or three different units in diverse areas and now we are getting into production per well, and we are getting to a point where we just can't answer anything. I think we ought to investigate those before we make any more of an answer.

Q. Well, let's see right here, maybe we can get it here.

A. Potter 1, 38 billion.

Q. That's accumulated?

A. Yes, but we can consider it under total pounds produced.

The Trial Examiner: The hearing will stand in recess for five minutes.

(At this point a short recess was taken, after which proceedings were resumed as follows:)

The Trial Examiner: The hearing will be in order.

By Mr. Keffer:

Q. All right, now, Mr. Stevens, you had on your work sheet here the matter that we were discussing a moment ago. Now let's see if we can't hurry through this. I'll read from this sheet and you say if it is correct or not.

In Potter County 1 your total production in 1939—

A. 1939—I just figured these out by total.

Q. I know, but I don't want it that way. Your total production in 1939, 11,214,000,000 feet, wasn't it?

A. Yes.

Q. Your decline in rock pressure for that same period was eight pounds, wasn't it?

A. Yes.

Q. All right, now, we come over to Potter County, Quadrant 3. All right and your production from Potter County, quadrant 3 was 5,225,000,000, wasn't it?

A. Yes.

Q. Your decline in rock pressure was four pounds, wasn't it?

A. 4.3 billions per pound.

Q. All right, now, let's take another view of it. The Canadian River production in Potter County, Quadrant 1, was 6,712,000,000 wasn't it?

A. Yes.

Q. All right, that is slightly more than Canadian River's production in Potter County, Quadrant 3?

A. Yes.

Q. You had a 4-pound drop in Potter County, Quadrant 3, as against an 8-pound drop average in the Potter County, Quadrant 1, with very little more production by Canadian River in Potter County, Quadrant 1, is that correct?

A. That is correct on the basis of total quadrant pressures; however, when you start to compare—make a comparison, a basis of comparison, with Canadian River Gas Company, you should consider the pressures of Canadian River Gas Company.

Q. What are the pressures of Canadian River Gas Company's wells in that area, the drop in pressure in the two years?

A. Between 1938 and 1939?

Q. Yes. It would still be about 8 pounds, wouldn't it?

A. I don't know. They are considerably higher than the quadrant average.

Q. Do you know that to be a fact?

A. Yes.

Q. All right.

A. Mr. Watson, I believe, stated there was 375 pounds in 1939.

Q. In Quadrant 1?

A. Not quadrant 1.

Q. And it was all Canadian River?

A. All Canadian River.

Q. You are bound to have that somewhere there. If you will give it to me I will have it computed and bring it back to you for comparison.

A. Of course, they are all on these work sheets but they are computed to an average.

Q. All right, let us assume, while checking it, that the per pound drop of Canadian River production in Quadrant 1, Potter County, was about 8 pounds from 1938 to 1939.

A. Yes.

Q. All right, in Quadrant 3, Potter County, it was 4 pounds—that was 4 pounds as you show it in there from 1938 to 1939?

A. If you make it clear that this assumption of pressure loss is on the basis of the total quadrants which contain at least three and one-half times more wells than does Canadian River alone, and they are lower pressured wells, and a comparison on the basis of quadrant pressures apply to Canadian River production is not tenable, Mr. Keffer. You have to compare like—

Q. We are going to compare Canadian River's production. That is what we are checking now.

A. You refer to this 4-pound drop. That is the total—

Q. That is all Canadian River. Nobody has anything else in Quadrant 3—

A. I beg your pardon. That is right as to Quadrant 3.

Q. On Quadrant 1 we are going to take it on Canadian River wells alone.

A. Yes.

Q. Let us proceed. Whenever you have that sort of a situation, Mr. Stevens, that is, where the pressure—all right. Here we have it right here. The pressure drop on

Canadian River wells in Potter County, Quadrant 1, 1938 to 1939 was 11 pounds. That is more than your quadrant average, isn't it?

A. Yes, 11 pounds.

Q. 11 pounds. In Potter County, Quadrant 3, it was 4 pounds, wasn't it?

A. All right.

Q. Will you figure out the production per pound pressure drop in the two quadrants and compare them? In fact, you can do that almost in your mind.

A. On Canadian River production and Canadian River pressures?

Q. Yes, that is right. You take Quadrant 3 where you have a production of 5,351,000,000 with 4 pounds drop. Divide 4 in to that and you have about 1 billion 3, don't you?

A. Over here you must consider Canadian River production 6.712 with an 11-pound drop.

Q. How much did you have there per pound drop in pressure?

A. .61 billion per pound.

Q. .61 billion per pound? It is bound to be a lot less than that. It must be 671. This is in billions and you divided by approximately 10, and as the result you got .6.

Q. It wouldn't be 6 billion, it would be 671—I see.

A. That is correct.

Q. You had .672 billion?

A. 6.712 and you divided by 11.

Q. You couldn't still have 6 something, could you?

A. I said .6.

Q. I beg your pardon. I thought you had your 6 and then your point. You are right. Then your production per pound drop on Canadian River's wells in Potter County, Quadrant 1, is .617 billion, is that right?

A. Potter County, Quadrant 1, yes.

Q. And in Quadrant 3, Potter County, it is 1.3?

A. Yes.

Q. So your pressure is dropping twice as rapidly in Quadrant 1, Potter County, compared to your production, than it is in Quadrant 3, Potter County, isn't it?

A. Let's see. We get less production per pound in Potter County, Quadrant 1, than we do in Potter County, Quadrant 3.

Q. That is right.

A. We get less production per pound in Potter County, Quadrant 1, than we do in Potter County, Quadrant 3.

Q. In fact, you get just about half as much in Potter County, Quadrant 1, as in Potter County, Quadrant 3.

A. That is right, and that is exactly as it should be.

Q. Why is that exactly as it should be?

A. For the reason that in Potter County, Quadrant 3 you have both a larger area and a larger number of wells taken from a larger size tank, as it were, and the larger size tank, if it can be referred to as a tank for simplicity, will give you more production per pound than will a smaller sized tank because it is simply—

Q. It will give you more, but you get less in that large tank, don't you, just half as much as you did in the smaller tank?

A. Potter County, Quadrant 3, is a larger tank than Tank 1.

Q. Potter County, Quadrant 3, is larger than Tank 1? I think you are way off on that.

A. I beg your pardon. Well, it gives the difference in that case could only be accounted for by the volume of gas in there.

Q. The volume of gas where?

A. I was assuming for the moment that the areal size might be an indication of the total volume of sand or something.

Q. If it was an indication when you made this assumption, it is still an indication, isn't it?

A. It isn't—

Q. Answer me. Isn't that a fact? If you made a correct assumption a while ago it is still correct right now, isn't it?

A. Well,—

Q. Answer me. Just say yes or no.

A. It is not restricted as you are trying to restrict it.

Q. I am not trying to restrict it. I am making the very simple statement you made—

Mr. March: I object to the witness answering the questions *extemperaneously*. They are unfair to us and unfair to the witness.

Mr. Keffer: There is nothing *extemperaneous* about this.

The Witness: You tell me—

Mr. March: He makes the witness figure out the problems as he goes.

The Trial Examiner: This particular cross examination, Mr. March, is directed to a voluntary statement made by Mr. Stevens. It certainly is permissible. If Mr. Stevens is going to insist upon volunteering these statements, I can't prevent Mr. Keffer from questioning him about them.

Mr. March: The fact is he volunteered to work out the problem here.

The Trial Examiner: No, no.

By Mr. Keffer:

Q. Mr. Stevens, you said there ought to be more production per pound drop in pressure in Quadrant 3, Potter County than in Quadrant 1, Potter County,—

A. That is the thing—

Q. Wait a minute, let me finish my question.

—because Quadrant 3 was so much larger than Quadrant 1, and you had a bigger tank to produce from, therefore, the production should be more per pound drop. Now, if that were true then, it is true right now, isn't it?

A. If it were true then—

Q. You made an untrue statement when you said that, did you not?

A. I assumed, as I started to explain that if the areal distribution is the only criterian involved as indicating the size of the thing, that is the relation indicated to be expected—

Q. When you found it worked just the opposite, you wanted to abandon that one, didn't you?

A. You have to—I did it for this reason: If that isn't apparently the criterian, the surface area as indicated by the map alone, then something else must apply, and I was attempting to state that.

Q. What is the "something else"?

A. Without knowing the exact producing thickness of Potter County, Quadrant 3, the smaller one, as compared with Potter County, Quadrant 1, the larger one, it is impossible, of course, to define whether that particular thickness

may be the accounting difference, the difference accounting for—

Q. What you say, then, is that you have more gas per acre—

The Trial Examiner: Wait a minute.

Mr. Keffer: I beg your pardon.

The Witness: The other thing that accounts in part, without attempting to name the degree for the larger production per pound in Potter County, Quadrant 3, is occasioned certainly in some degree by the drainage from Moore County, Quadrant 3. The combination of those, or whatever else may have occasioned it, is obviously an explanation for the difference, and what those other things are is not contemplated in the study; I don't even care what they are.

By Mr. Keffer:

Q. You just don't know what they are?

A. We don't know what they are in degree, no, sir, as stated before.

Q. All right, suppose the productivity of Quadrant 1, Potter County, per acre was greater than it was in Quadrant 3, Potter County; that is, it is just a richer producing area, would that have anything to do with it?

A. If it were a richer producing area?

Q. Yes, if Potter County, Quadrant 3, were a richer producing area—I mean, Potter County, Quadrant 1, were a richer producing area than Potter County, Quadrant 3, would that have anything to do with it?

A. (Pause.)

Q. Just answer it without looking at your answer there before you first.

A. That is—

Q. All right, look at it.

A. You are dealing with thickness of sand and the early extent of that thickness—in other words, the size of the tank.

Q. That is right.

A. The size of the tank consisting of sand and thickness of sand undoubtedly has some bearing in it, so it wasn't part of this study, Mr. Keffer.

Q. Right there, if the size of the tank, or in other words the richness of the area was greater in Potter County,

Quadrant 1 than it was in Potter County, Quadrant 3, then you would expect a smaller decline per pound with respect to the same production as compared to production than you would in Potter County, Quadrant 3, wouldn't you?

A. A smaller production per pound?

Q. You would expect—no, you would expect a larger production per pound drop from a richer area than you would from an area that was not quite so rich?

A. That is possibly true, but they are indicated not to be that rich.

Q. In fact, they indicate the reverse, don't they?

A. Yes.

Q. All right.

A. You were asking me to evaluate that difference in proportion—

Q. You were just saying you couldn't evaluate it and I am trying to help you. I am trying to do you a favor.

Mr. March: This is a good example of the cross examination. He said that he couldn't do it and he said he would help him—

Mr. Keffer: The point is, he has evaluated it and that is the only thing I am coming up to.

The Trial Examiner: Objection overruled.

By Mr. Keffer:

Q. Mr. Stevens, the map here shows 22,279,000 recoverable reserves per acre in Quadrant 1, Potter County, doesn't it?

A. You are reading from the map?

Q. Yes. Look at it and check it.

A. The remaining reserves on a weighted basis.

Q. What weighted basis?

A. The weighted basis Mr. Hammer used.

Q. Mr. Hammer on the same basis shows 13,426,000 per acre remaining in Quadrant 3, Potter County, doesn't he?

A. Yes, he does.

Q. So everything we have mentioned so far, producing thickness of sands, size of tank, or container, richness of production, all should operate in favor of Potter County, Quadrant 1?

A. Just on the face of it, yes, but—

Q. Just the reverse—

A. I—

Q. Excuse me. Go ahead.

A. It is necessary again to point out the difference in the method used by Mr. Hammer and myself, he incorporating the adjacent quadrants which I did not do.

Q. However, the reverse of those things are true, aren't they?

A. Indicated by these figures—

Q. Indicated by these figures which you yourself prepared?

A. But the effect of the drainage into Potter County, Quadrant 3, from Moore County, Quadrant 3, you haven't given that any consideration.

Q. All right, have you given any consideration to the drainage out of Potter County, Quadrant 1?

A. Except as it is incorporated in the figures.

Q. All right. Precisely so, how is it incorporated in the figures?

A. In whatever degree it affects it.

Q. In pressure loss?

A. In Potter County, Quadrant 1?

Q. Yes. That is right. That is the only way it could be incorporated in your figures for drop in pressure, isn't it?

A. Yes.

Q. That is right. Now, you take that drop in pressure, if you didn't have any migration out your would have had a lesser drop in pressure than you would have had if there was no migration out, wouldn't you?

A. That is—

Q. It is obviously so.

A. It is a statement of principle.

Q. There shouldn't be any argument about that, should there?

A. That's right.

Q. Now, all of the factors you have been naming that should explain this difference, the fact it is working in reverse order, which is somewhat a definite indication you are getting a much less production per pound drop in Quadrant 1, Potter County, than you are in Quadrant 3, Potter County, because of the loss of gas from Quadrant 1 by underground drainage, isn't that a fact?

A. If you divorce the question entirely from thickness, and so on, that would be because—

Q. Including thickness. We have more thickness on your own statement in Potter County, Quadrant 1, than on Potter County, Quadrant 3.

A. As to whether this is occasioned by local drainage, the map would probably serve as the best criterion to answer that, and that is Mr. Hammer's exhibit.

Q. All right, I am going to finish on this.

You show in Potter County, Quadrant 1, present wells are going to produce 340,500,000,000 cubic feet of gas, don't you?

A. Yes.

Q. You show, or Mr. Hammer shows, that the total amount of gas under the leases in that area is 1,078,766,000, doesn't it?

A. Yes.

Q. You show, then, under the present wells we are not going to produce more than a third of the gas that is under that lease, don't you?

A. Under present wells, yes, sir.

Q. Under present wells. You show a greater concentration of wells in that quadrant than you do in Quadrant 3, Potter County, or any other portion of Canadian River's total quadrants, don't you?

A. Yes, but we also pointed out that there was room for more drilling, which indicates room for more wells, and that those wells we added would necessarily add to accessibility of reserves.

Q. All right. You mean that we can step up our production and cut down drainage? Is that what you are trying to say?

A. You could step up your recoverable reserves by drilling more wells. That is all I am attempting to say.

Q. I am trying to go very rapidly, Mr. Stevens, but this is an important point, one of the most important ones in this entire question of reserves.

Your own figures as you have made them show that from the standpoint of the present wells in Quadrant 1, Potter County, that we are only going to produce one-third of the gas in that quadrant, don't they?

A. That is right.

Q. That is absolutely correct. All right, now, if those present wells—and there are 24 of them—are sufficient to drain that quadrant of its gas, then you have calculated not qualitatively but quantitatively by your own figures the amount of gas that is going to be lost from that quadrant by drainage over 600 billion feet or two-thirds of it, haven't you?

A. It is indicated there are not enough wells in there to drain that quadrant. That is the point in the matter.

Q. You say it is indicated because those wells are only going to produce 340 billion while it is shown there is over a trillion there. That is the way you say it is indicated and that is the only proof you have that it is indicated?

A. On the basis of the study, that is right.

Q. You say it is indicated because you take your answer and figure back down, don't you, and that is the only proof you have of it?

A. You draw the conclusion from the answer as you do in any problem.

Q. All right. Now, as a matter of fact, if those wells are only going to produce 340 billion cubic feet and there is more than a trillion cubic feet there then is it not a logical assumption that we are going to lose two-thirds of that as the result of underground drainage from your own calculations?

A. No, the conclusion is that you need to drill more wells and that is the only conclusion.

Q. You are shutting your eyes to drainage, aren't you?

A. Except as they are incorporated in the figures.

Q. I have cited your figures. That abnormal drop in pressure with respect to production as compared to other areas where the reverse ought to be true. What more do you want than that, Mr. Stevens, as an engineer, geologist or as an ordinary layman?

A. Well, to me it simply raises the question that—simply points to the conclusion that more wells are necessary—

Q. You say it simply points to the conclusion that more wells are necessary, because you are assuming there will be no drainage. Let's get on the other side a minute.

A. I haven't assumed drainage in any case. I have admitted local drainage where local drainage is located and I think it is from this point or the point of view of drainage

locally a matter for the company to consider whether they drill wells to reduce that local drainage. The point is that the gas is there and this will be the recoverable gas by these present wells, and if there is drainage you separate your drainage if you claim there is drainage or you know there is drainage—

Q. Maybe so. You say that these wells when they are down to 25 pounds, wells that are pretty well scattered over the quadrant, will have produced only 340 billion feet of gas. Now, you have said that without any quibbling, haven't you?

A. Yes.

Q. That is in your report. You have also said that when those 24 wells are down to about 25 pounds that practically all of the gas in that quadrant is going to be done, haven't you?

A. Except as is retained in higher pressure intermediate areas.

Q. And you said you thought if the same pattern continues, 50 pounds would be the highest pressure anywhere in it, and that in the southwest corner. You said that, didn't you?

A. We have assumed that 50 pounds pressure is an arithmetical subtraction. It may be local; it may not be. There is good reason to believe it will be over 50 pounds, probably a little better reason than to assume it is 50 pounds.

Q. It is not going to be two-thirds of 430 pounds, is it?

A. I don't know what it will be.

Q. That is what you are going to have to make your figures come out, isn't it? You will have to have the average all over it. You would have to have big slices of the virgin pressure to have over 600 billion left in there after you produced 340 billion, wouldn't you? You would have to have two-thirds of your pressure left when every well in the area was down to 25 pounds and you know very well that is an absurdity, don't you?

A. I think we are getting away—

Q. Answer me if that wouldn't be an absurdity.

A. As you stated it it would.

Q. I have stated it precisely as you calculated it, haven't I? I haven't deviated an iota from your calculation, have I?

A. I think it should be pointed out again that this figure

means that on the basis of your present wells you will recover this 340 billion.

Q. That is right; which is a third, approximately, of the remaining reserves, isn't it?

A. About a third of the figure given by Mr. Hammer.

Q. If you wanted to qualify his estimate, I will qualify it—

Mr. March: I object to haranguing with the witness.

Mr. Keffer: It was just a side remark—

The Trial Examiner: We will strike it. Go ahead.

The Witness: When we get right down to it, this estimate means—I think it is true that Mr. Hammer's estimate means that that is the gas that is under there. This is the gas that would be recovered by present wells. The difference between that third figure and that figure given as one-third in relation to Mr. Hammer's; in other words, the two-thirds, is the amount that you could get additional by drilling additional wells.

By Mr. Keffer:

Q. All right. Right there, I have just another question there, and I think we can make that very clear.

You say that the present wells would produce in round figures a third of what Mr. Hammer says is there remaining down to 25 pounds abandonment, don't you? That is what your figures show?

A. Yes.

Q. All right. Now, it would follow that when you have produced that one-third and every one of those 24 wells are down to 25 pounds, then for you to have two-thirds of it left, you would have to have two-thirds of that pressure, wouldn't you?

A. You would have to have two-thirds of the pressure left but you are saying there is no drainage from there—

Q. Wait a minute. You are saying there was not—

A. I didn't say there was not.

Q. All right. Then, you now say there was some drainage from there?

A. I believe on one side there is some local drainage.

Q. All right, but is there any difference between local drainage and any other kind of drainage?

A. Regardless of what happens, drainage or no drainage —you say "drainage." I believe it has in Potter County, Quadrant 1. I believe some local drainage was established for Potter County, Quadrant 1. It doesn't mean in those immediate areas it is going to be two-thirds of the pressure; it means on the basis of this record you are going to get this gas.

Q. That is right. On the basis of your calculation you say if we drill a certain number of additional wells and we have so much reserve for such wells you are finally going to get over a trillion feet in Quadrant 1, Potter County?

A. If you would drill sufficient wells in the quadrant you would get a trillion feet.

Q. You don't know how many wells that would be?

A. I haven't attempted to state.

Q. You also say "when we have produced 340 billion, or a third from our present wells every one of those present wells are going to be down to 25 pounds abandonment pressure," don't you?

A. Their average will be 25. That is the equivalent of stating that.

Q. I will take that qualification.

If the average of every one of those wells, every one averaged in is down to 25 pounds, there couldn't have been but very little—I will say 10 per cent more gas remaining in the higher pressured portion of the quadrants; that is, between 25 pounds and that higher point?

A. I don't know how you figured the 10 per cent. I can't check it.

Q. I picked the figure out of the air. It couldn't be very much, isn't that right?

A. As to "very much," very much is a relative matter.

Q. I know. You can state it in general terms that there isn't going to be much gas. I think anybody could state that.

A. Let me state it this way: If in a given place you had 25 pounds in some illustration and you used 50 pounds, that 50 is 100 per cent more than 25 in that case.

Q. All right.

A. So if you were talking about 10 per cent and I were to check you on 10 per cent, that would be a pound and a half or a pound and a quarter more, which is a little bit peculiar.

Q. When every one of your wells are down to 25 pounds, certainly you are being very generous when you assume that the pressure over the entire area would be more than fifty pounds on an average, wouldn't you?

A. I don't know what it would be.

Q. I know you don't know what it would be, but that would be a most generous estimate, wouldn't it?

A. If—

Q. You can answer that question.

A. You can't without considering one point, that that last 25 pounds differential is going to be a lot harder to get—a reduction in pressure, that is, a flattening to the difference of 25 pounds you have stated, is going to be a lot harder to get than any other set of differentials of 25 pounds.

Q. That is right. Even on any other theory you are not going to get it down to 25 pounds, are you?

A. That is right.

Q. I don't care if you drill a hundred more wells, you are not going to get it down to 25 pounds, are you?

A. Not minutely speaking.

Q. Of course not. Then when you figured there was so much left there at 25 pounds you have to make some adjustment for that that you are not going to get, regardless of how many wells you are going to drill?

A. What adjustments?

Q. There is something more than 25 pounds in there you are never going to get because of these pressure differentials?

A. That brings you to the point of what 25 pounds means.

Q. I assumed 25 pounds meant 25 pounds.

A. We have talked about it in regard to 25 pounds at the well head.

Q. That is true. You said a 25-pound well head all through the examination, so it means just that and not something else?

A. These figures, if you treat them strictly, mean an average of 25 pounds, that is true.

Q. At the well head?

A. At the well head.

Q. That is right. All right, go ahead.

A. The difference between 25 pounds and what the actual pressure would be, if you were able to find that and average

it out, if it were possible to average every square foot of it, that difference in pressure represents an additional amount of gas that isn't contemplated here.

Q. Well, I know. We needn't go into that. When you have 25 pounds well head, if you are going to produce any gas you have to have something more than 25 pounds out away from the well. That is simply stated and is the whole thing, isn't it?

A. That is true.

Q. All right, so when you say "recoverable down to 25 pounds well head," then you have to make some adjustment for that somewhat higher pressure out from your well, which you are not going to recover down to 25 pounds well head, are you?

A. I see your point, but that 25 pounds is—all of these other pressures we have are actually higher than we have stated for the same reason.

Q. What do you mean by higher?

A. They lack a degree of equalization to a stabilized point just as they will at 25 pounds, so they are all off to that extent.

Q. Your 430 pounds had no variation?

A. This 4-year period hasn't anything to do with this 430 pounds.

Q. I know, but in taking pressures today and figuring them back against 430, it has something to do, doesn't it? If they were off in 1935 they would still be off in 1939, and in about the same proportion in all probability, so the result is the same whether they were constant or off, isn't that right?

A. I think so.

Q. I don't think there is any argument about it. I am going to leave that. Just this one question:

You said if you had been estimating reserves you would have followed Mr. Hammer's method, is that right?

A. Reserves under leases, yes.

Q. Reserves under leases?

A. Yes.

Q. Do you know what his method was?

A. In general I have heard him describe it here.

Q. You are not so certain you would follow it if you didn't know precisely what it was?

A. As I understand it—it has been presented here—

Q. I am going to ask you one thing about it, then.

His method averaged or weighted rock pressure averages from an areal standpoint, didn't it, with respect to area?

A. Yes.

Q. Let me ask you this: Where there are volumes, as announced by Boyle's law, that vary with pressures; that is, the pressures vary with volumes or areas? Just state Boyle's law. Maybe I have it backwards, I don't know.

Mr. March: The question is that you want him to state Boyle's law?

Mr. Keffer: The question is that the pressure varies with volumes.

The Witness: I thought you referred to a deviation from Boyle's law.

Mr. Keffer: No.

Q. Boyle's law, from a grammar definition of it, is that pressures vary with volumes, isn't that right?

A. Yes.

Q. And the pressures do not vary with areas, do they?

A. The manner in which you used pressures and areas—

Q. Mr. Boyle didn't say anything about area when talking about the varying of pressures, did he?

A. Pressures can be weighted against any factor pertinent to those pressures.

Q. The point is, volume is the pertinent thing to weight with the pressures and not areas; that is the whole point. You hit it on the nail head—

A. Those volumes occupy areas and in a sense are synonymous with areas.

Q. Volumes are synonymous with areas?

A. Well, when you talk about an acre pound volume, you are talking about a volume in an acre.

Q. All right, I am going to get away from that in just a minute. If we knew the volume under every one of those areas and weighted pressures to that volume, we would get a perfect answer under the application of Boyle's law, wouldn't we?

A. Yes.

Q. All right, now, just one more question further.

When we don't know the volumes and we take the areas and weight it that way, we are necessarily giving every area the same volume, aren't we, in that sort of a weighting?

A. When you consider areas, you are in effect considering the volume under that area.

Q. But you are considering every area has the same volume, aren't you?

A. Within certain limitations.

Q. What do you mean by "within certain limitations"?

A. That is the effect of volume differences in the area in question as weighted into the pressure.

Q. How?

A. In that sense, while you reduce your figure to an area, you are incorporating the *varities* or the divergent characteristics, the differing characteristics of those areas into one quadrant, the area being the acre pound for the quadrant. It is obviously understood that without wells on every square foot you couldn't do it on a square foot basis.

• • • • •

Q. When you are averaging pressures against acreage you are omitting one of the fundamental principles of Boyle's law, aren't you?

A. I don't know what principle you mean.

Q. The principle that pressures vary with volumes and not with areas.

A. I believe I answered that in this manner, that the volumes taken out under those areas, the volumes you omit are of course a part of the expression of Boyle's law.

Q. When you are weighting pressures against acreage, when do you consider the volumes taken out with respect to each particular year? How do you consider it?

A. That—

Q. The fact is, you don't consider it, do you?

A. Don't consider what?

Q. Volume as related to each particular area between isobars on the map.

A. Those are weighted to a single area and in that respect they do.

Q. In that respect they do. You take area 1 which lies between any two isobar lines and you have a pressure of 400 pounds, we will say. You multiply that by the acreage, don't you?

A. Yes.

Q. You come to area 2 that has 390 pounds. You multiply that 390 pounds by the acreage, don't you?

A. Yes.

Q. You come to area 3 which has 380 pounds. You multiply that by acreage, don't you?

A. Yes.

Q. And then you add all of those up, don't you, all the way through the field?

A. Yes.

Q. And you divided by the number of acres to get your weighted pressure?

A. Yes.

Q. And you haven't considered volume in one single instance, have you?

A. What you have done—

Q. Answer my question. You haven't considered volume in a single instance, have you?

Mr. March: Let him answer the question.

Mr. Keffer: He can answer the question yes or no.

Mr. March: He can explain it.

Mr. Keffer: He can answer the question yes or no, and then he can explain it.

The Trial Examiner: Answer the question.

The Witness: No, with this explanation—

By Mr. Keffer:

Q. Go ahead.

A. —that you are right there at the point where you have not considered volume. What you have done to that point is that you have weighted the diverse points of that area under those contour—

Q. Weighted acreage against pressure, haven't you?

A. Yes.

Q. And not volume, have you?

A. But—

Q. Not volume?

A. Not at this point.

Q. All right.

A. And at that point when you do obtain that weighted pressure you have reduced those numerous tanks of 10-pound pressure differences, we will say—that is a good illustration—to what the pressure would be as nearly as can be figured if the entire series of tanks or quadrants were used to full equalization. That is the nearest approximation of it and that is the point that you have arrived at at this point. The next point is to—in other words, you have determined a pressure or the very best possible pressure representing that area having diverse components and with that you treat volumes and that is the way Boyle's law works.

Q. You treat the volume after you get the average? You didn't treat volume before you got the average?

A. It isn't my understanding that volume worked in at that particular point—

Q. Of course not. Now, when you do it that way you are considering that all areas have the same volume, aren't you?

A. I consider all areas have the same volume?

Q. Yes.

A. All areas have the same volume?

Q. That is right.

A. I think Mr. Hammer ought to answer that point.

Q. You can answer it. You are familiar with how you do it.

A. At this point we have weighted average pressures against acreage which is the effect of making one tank out of numerous diverse tanks.

Q. From an areal standpoint?

A. From an areal standpoint.

Q. But not from a volume standpoint?

A. The whole volume—

Q. But not from a volume standpoint?

A. That is right. That has been admitted.

At that point the volume of gas is considered, as I understand it—If I am wrong I don't want to be bound by this, naturally—the volume is considered to have come from that one tank so treated, and if you had 5-pound isobars or

1/10-pound isobars, if it were possible to make those, the degree of refinement would be greatly increased.

If you had lesser distances as employed by many people, your degree of refinement would be a great deal less. As I understand it, that is subject to correction by Mr. Hammer on his own behalf. That is my understanding of the matter.

Q. All right. The whole point is when you weight pressures against acreage you are not following Boyle's law strictly? The obvious answer is yes to that.

Mr. March: You don't have to put the answer in his mouth. Let the witness answer the question.

Mr. Keffer: All right.

The Witness: You are following Boyle's law in that you are merely preparing the data to a convenient form for the application of Boyle's law, and the process isn't through until you use volume. Certainly the use of pressure versus volume is an expression of Boyle's law, so therefore I don't understand why you don't use Boyle's law.

Mr. Keffer: All right.

Mr. March: It is an old trick of Mr. Keffer to jump from the assumption to a practical thing and accuse the witness of having done that himself.

The Trial Examiner: I think we are proceeding under the assumption as originally stated by Mr. Keffer.

Mr. Keffer: That is right.

The Witness: We have an assumption where there is a high pressure area that does have some gas in it, though there is no well drilled on it.

By Mr. Keffer:

Q. Just how much volume would you assign to that area and how would you go about it?

The Trial Examiner: You are still speaking of an area having a 430-pound pressure without any gas in it?

Mr. Keffer: I will say there is a half-million cubic feet of gas per acre—

Mr. March: Wait a minute. Let me see here. First Mr.

Keffer takes this assumption, the assumption that we have an area that doesn't have any gas in it, yet it has 430 pounds pressure. That is Mr. Keffer's own assumption.

The Trial Examiner: That is right.

Mr. Keffer: Mr. March, if you will sit down I will change it.

Q. We have an area with 430 pounds pressure that has a half-million cubic feet per acre in it. How much volume are you going to assign to that under your method of estimating reserves?

A. If you knew that you had a half-million—

Q. We don't know it. We are assigning that.

A. The rest of the components of the problem haven't been stated and as I understand the method. Incidentally, I think I should say that not having made this study under this method, in spite of the fact that I say that I would have used the method, being in a position to use the method at some time, I would certainly go into a study of details which probably at the moment I have not fully considered. Not having gone into a study of it: therefore, I feel that answers I make under this hypothetical situation should be made with the reservation that they are all connected in principle.

Mr. Keffer: I wish the Examiner would please look at Mr. Stevens' exhibit, the first graph in that exhibit, which is the composite graph.

Q. Now, Mr. Stevens stated quite positively to Mr. March yesterday that you couldn't have drawn a line through or near the circles 1937, 1938 and 1939, which are circles around your points, without showing more reserve instead of less reserve. You made that very statement, didn't you?

A. Based upon the judgment of the time I drew the line.

Q. You made the very positive statement that on that curve you had given 1939 as much weight as you gave 1937?

A. As I gave 1937.

Q. You gave 1939 as much pressure as you gave 1937; you made that positive statement, as I recall it.

A. I perhaps did, if you say so.

Q. That is when I interjected yesterday—

Mr. March: Mr. Examiner, I object. If the witness doesn't know, he can say he doesn't know. He doesn't have to assume anything that Mr. Keffer says.

Mr. Keffer: The record speaks for itself.

The Trial Examiner: Go ahead.

The Witness: In an extension of this kind, as in subsequent cases, if I haven't made it definite I want to now, all points were considered in giving weight where at all such weight was justified, the exception being one or two where 1937 was way off.

By Mr. Keffer:

Q. To get back to my question, you want to let your answer stand that you made directly to Mr. March yesterday that you had drawn the most conservative line you could draw taking into account 1937, 1938 and 1939?

A. I think that is right. I think that is an honest statement.

The Trial Examiner: Did you mean, Mr. Stevens, that you didn't want that answer to stand, or you wanted it to stand?

The Witness: I wanted it to stand with reference to these three points, with the very slight qualification—not "qualification," "clarification" that it is an honest statement.

Mr. Keffer: I intended to go over these one by one but time will not permit.

Q. Suppose you leave that line right where it is, just clearing the south side of the circle numbered 38. Do you see that point?

A. Yes.

Q. Then you tilted your line a little to the northward out at 1937 to where it just barely touched the outside of the circle 1937, you could do that, couldn't you?

A. You could.

Q. Then you tilted it down necessarily when you tilted it up with 1938 as the pivot; and when you pivoted it up at 1937 you naturally tilted it down to 1939?

A. Yes.

Q. Do you know where you would barely touch the rim of the circle at 1939?

A. You could do that.

Q. Wouldn't that be a more accurate reflection of the circles 1937, 1938 and 1939, than the line you have drawn?

A. I am not sure. I would have to call your attention to another possibility—

Q. Just answer my question. You can answer it. You don't need a microscope to see it.

A. That, Mr. Keffer, is one possible way to have drawn it.

Q. When you made the positive statement you couldn't have drawn that line any other way, taking the three points into account without showing more reserve, you didn't state the truth, to make it blunt, did you?

A. I stated the truth in this respect—

Q. Part of the truth, then. All right, go ahead.

Mr. March: I object, Mr. Examiner. We don't like these insinuations in the record.

Mr. Keffer: Strike that part of it.

The Witness: The truth to you, rather to me—let me put it that way, as I don't know what the truth is to you—is that at the time of drawing that line it represented a very equitable way to draw that line. It should be also mentioned that each of the following lines with one admitted exception in which it could have been drawn another way, and that variation when we get to it will seem very small in a reduction of reserve. The other quadrants could not have been changed in any reasonable manner, giving due regard to all three points without increasing the reserve, and it is to be noted again that the results for the total quadrants of the Canadian River are the result of a summation, and this summation is shown here now. If this summation of equitably and conservatively drawn components comes to the point of being expressed by a line which falls in close proximity to the point plotted here as this does, it seems to me to be strongly begging for the point of accuracy to criticise a very minute variation when this is a summation of component parts.

Q. Maybe you can just answer one simple question and eliminate all of this. You could have drawn a line which

would have shown lease reserves and would have more nearly given weight to 1937, 1938 and 1939 than the line you drew? That is a fact, isn't it, without any qualification?

A. It would have been possible in the manner that you mentioned, but this is still a summation and I would like to—

Q. The summation is more important than any of its *constituant* parts?

A. A summation is a summation of *constituant* parts.

Q. This tells the whole story?

A. Each part is important.

Q. Of course, but you are not going to let a part of your total be given any more importance, certainly, than your total, are you?

A. Do you consider it no point, Mr. Keffer, that the summation comes to a certain figure and that must be a final point on your curve also?

Q. I don't know that I know what you mean. You were drawing to the answer, is that what you mean?

A. When this curve was drawn an answer was there and we had the answer.

Q. You drew to the answer regardless of where the curve ought to have been?

A. The degree of difference you refer to as the microscopic degree, Mr. Keffer.

Q. I think it would figure out quite a little bit of the time. I see that you ran it across the page twice.

A. This is the way it was drawn. The summation of other equitably drawn curves constitutes a fourth point on this; however, this wasn't drawn entirely with respect to it, yet it was drawn through it and you can—

Q. I don't desire all that explanation. I just desire one thing and that is that it is contrary to the statement you made yesterday that you could take those three points and give each of them greater weight than you are giving them here and draw a line that would show more reserves than you stated yesterday.

A. I don't think there would be any more or a particularly better line than shown here.

Q. I am not talking about the best line or the worst line. I am talking about giving consideration to the point there, which is the whole basis of the question.

A. You haven't given consideration to the fourth known point on the curve at all.

Q. Have you? What is the fourth point—the answer out here (indicating)?

A. That is one of them.

Q. Of course, I am assuming that you are working to the answer rather than assuming you are working from the answer.

A. You already have the answer—you have the answer when this curve was drawn.

Q. You told me that yesterday, that you drew to the answer, so since you had to draw to the answer your points might have been six inches below there and you wouldn't have considered any of them because you had to get your answer?

A. You had to get your answer?

Q. Yes.

A. Your answer is already here.

Q. Let's take these circles here. Suppose 1935 and 1936 and 1937 were lower and 1939 was up about where it was; 1938 was two or three points higher than where it is, you would have drawn your line precisely where it is drawn now?

A. If it had a different set of data, the answer would have been different and the—

Q. But you are drawing your answer out here?

A. The situation isn't comparable, Mr. Keffer.

Mr. Keffer: Mr. Examiner, I have done my very best to finish this long before now. There are a number of things that were opened up again on redirect that I feel should be gone into. It seems a question or two on them, if the witness will answer them, will dispose of that situation in fifteen minutes. I don't know, but I have quite a few of them noted here.

I hesitate when matters are opened up again to let them stand there as the final words or the thing to be considered when maybe they are contrary to practically everything said before that. That is the thing that makes an examination of this kind to me the most difficult thing I can conceive. I have been trying to rush through here and get this examination completed before 12:30 and I haven't done it. I am sorry that is the situation, too. However, I would like

a few more minutes this afternoon to see if I can't finish the examination.

The Trial Examiner: I want to be considerate under the circumstances, Mr. Keffer, but I would like to get through with Mr. Stevens if at all possible before we recess for the lunch hour.

Mr. Keffer: I will try to do it.

Q. We decided yesterday after some rather lengthy cross examination that if the ratio of production as you have found for Canadian River is not changed that your dotted line would not be changed by additional wells, didn't we?

A. That was the case, yes, sir.

Q. How's that?

A. That was the case, yes, sir.

Q. That is a correct statement, isn't it?

A. Yes.

Q. It is obviously so?

A. Yes.

Q. Then we also determined yesterday from your past experience and your past curves that the drilling of additional wells didn't change your top curve on Exhibit 182, your summation?

A. If they had no production record reflecting or requiring a change.

Q. All right. We even decided that for the year 1937, 1938 and 1939, even where they did have production records, that additional wells didn't change your line, didn't we?

A. That is right.

Witness further testified on redirect examination (Vol. 64, pp. 9181-9185) as follows:

Q. Mr. Stevens, on recross examination there were a great any questions asked you in regard to a hypothetical case something like the following, and I will draw this hypothetical picture and will ask you some questions in regard to it.

I have right here—let's assume we have here a gas field—that this piece of white paper is a gas field and we drill right here (indicating), and the pressures in that well are

400 pounds. Now, that is the only well we have at 400 pounds. Extending out from that 400-pound well is an area which has, we'll assume, a pressure of 410 pounds. We'll assume, to make the illustration similar to the one given by Mr. Keffer some time ago, that it extends out five miles from that well, around there, and there are not any other wells around there.

Now, we take all the gas out of there to 25 pounds. Say we do it in a shorter period of time, say we do it in ten years; say we take all of the gas out of this well down to 25 pounds, all of the gas you can get out of this well down to 25 pounds.

Would you or could you in doing that over that short period of time drain all the gas out of this area out here (indicating) in the 410 pound belt, with the exception of 35 pounds?

A. If that represented one well in the field—

Q. I am talking about just in this field, this distance of five miles here, so it would be comparatively—well, we won't limit that. It is similar to the Panhandle field, we'll say.

A. You wouldn't drain the entire area, no. You would drain the area to such a degree as would give a pressure of 25 pounds, however, and there is some higher pressure outside, naturally.

Q. If you pulled this well down to 25 pounds, would it take some time for the pressures to build back up over 25 pounds before you could ever drain this area out here?

A. Oh, yes. That is a foregone conclusion because you would have to establish another new pressure condition conducive to a differential.

Q. In other words, to assume that when you took this well down from 400 pounds to 25 pounds you would have to assume to get all of it out that you had in effect all one container without any obstructions at all and the perssures wouldn't have to build up, is that right?

A. Yes, either that or greatly—and I mean greatly extended time. That is where the time facor comes in.

Q. Is that what you meant when you said back there in your testimony that present wells in the quadrants here could drain the whole territory if it took a thousand years to do it?

A. If you wanted to assume a purely hypothetical case, that is sometimes stated, but never taken very seriously. That would be the case perhaps.

Q. Ordinarily do pressures in wells build back up as fast as the gas is withdrawn if they have a large area to drain from—even if they have a large area to drain from?

A. As compared with something else?

Mr. March: Read the question.

(The question referred to was read by the reporter, as set forth above.)

The Witness: Well, that is a function of permeability that would have to be stated and if it were low permeability it would take a longer time, and if extremely high it would take a shorter time. I think it is a relative question and the only answer that can be given to it is that relative answer.

By Mr. March:

Q. Mr. Stevens, if you had a half-dozen wells in the Panhandle field, in the western part of the Panhandle field and that is all the wells you had there and if you waited an indefinite period of time, say a hundred thousand years, would it be possible for you to drain all the gas from the Panhandle field, in the western part?

Mr. Spencer: Is this based on one hundred thousand years?

Mr. March: This is based on hypothetical hundred thousand years.

Mr. Spencer: You are talking about one hundred thousand years, all right.

The Witness: Well, they say that hypothetical condition is sometimes stated as a means of illustration of principle, but of course in any sense of practicality it would be—

By Mr. March:

Q. Isn't it just as sensible to say that you can drain all of the gas from the Panhandle field—from the Canadian River acreage, in any reasonable length of time—

The Trial Examiner: There is no use opening that point up again, Mr. March. It has been gone into and gone into.

Mr. March: All right, sir. One more question.

Q. Mr. Stevens, you have been asked a great deal of questions about the undergfound geology of the Panhandle field and its functioning. I will ask you this question: Whether or not you have made a study, a careful study of the underground geology of the Panhandle field of Texas.

A. Not that kind of a study, no.

Mr. Keffer: What was your answer?

The Witness: No.

Mr. Keffer: No?

The Witness: No.

By Mr. March:

Q. Then you don't know exactly the full particulars in regard to the functioning of permeability, porosity, drainage, pay thickness, in the Panhandle field, do you?

A. As explained several times, I believe I have not evaluated those in any respect except as they may be themselves evaluated by the figures used which were pressure and volume.

Q. Would you feel qualified to testify in regard to the underground geology of the Panhandle field, since you have not made a study of the same carefully?

A. No, I wouldn't, except on only the most casual considerations.

Q. You have just made a study of the production and pressures as reflected here in your exhibit?

A. As far as this exhibit is concerned, that it all which that subject—that subject has been employed only as explained in connection with the exhibit by the use of pressure volume data and not through any evaluations of its general or specific aspects.

Witness further testified on direct examination (Vol. 65, pp. 9486-9504) as follows:

Q. Mr. Stevens, you are the same Mr. Stevens who has testified heretofore?

A. Yes, sir.

Q. I hand you an exhibit entitled "Canadian River Gas Company Availability Study," and ask you if you prepared that?

A. Yes.

Q. Did you prepare that yourself or was it done under your supervision?

A. I prepared it myself.

Q. Is it true and correct to the best of your knowledge and belief?

A. Yes.

The Trial Examiner: Mr. March, do you wish to have this marked for identification?

Mr. March: Yes, as Commission's Exhibit No. —

The Trial Examiner: It will be marked for identification as Exhibit No. 197.

(Exhibit 197, Witness Stevens, marked for identification.)

By Mr. March:

Q. Mr. Stevens, there is a written statement I believe in this exhibit running through from Pages 1 to 9, is there not.

A. Yes.

Q. Will you please proceed to read that statement?

A.

"Canadian River Gas Company
Availability Study

The availability study of wells of the Canadian River Gas Company has been carried out on a dual basis:

1. For 92 wells producing December 31, 1939;

2. For 97 wells existing, connected, or to be connected in 1940 or shortly thereafter. The additional five wells include two old wells not previously connected (Bivins A-22 and Masterson B-5) and three wells drilled in 1940 (Thompson A-3, B-3, and Masterson A-5).

All volume figures are on a 14.65 pound base.

The availability study was first contemplated for the date of December 31, 1939. More recent data in the form of back

pressure curves and data for 1940 are now available, and the dual basis has been adopted. In that part of the study dealing with (1), the availability is determined with respect to 92 wells; and in that part of the study under (2), is shown the availability of the 97 wells which are connected in 1940, or will be connected in that year or soon enough thereafter as to require consideration as an active source of supply.

On the dual basis stated, the availability study will determine:

(a) The amount of capacity available from wells connected, or to be connected at mid-year and end of years 1939 and 1940;

(b) The amount of capacity available from present wells at future dates, at pressures expected to exist at those future dates;

(c) The approximate dates at which additional wells are indicated to be necessary to supply a maximum 24-hour demand.

These objectives are accomplished by calculation, and illustrated graphically by weighted rate of decline curves, which show capacity at any pressure, and decline of capacity with decline in pressure.

The back pressure curves and data for 1940, for individual wells, used in the calculation of weighted rates of decline, were supplied by a representative of the Canadian River Gas Company. These curves and data are the results of the 1940 mid-year tests carried out by the Texas Railroad Commission and the company. The curves and data were stated to be identical with those in the Railroad Commission files. These curves are accepted, at least tentatively, as representing the individual wells' characteristic rate of decline in capacity with decline in pressure. Their construction follows, and accomplishes, basically, the general procedure and results described in Monograph 7, published by the U. S. Bureau of Mines.

From these curves and test data, was determined a weighted average rate of decline representing what might be considered a typical well; also a weighted rate of decline

for total Canadian River wells, under the two bases stated. The method used is one in which pertinent factors of individual wells were given their proper weight in the calculation of points which were plotted as a straight line on log paper. These curves, whether for the average well or total wells, represent the weighted rate of decline of capacity with decline in pressure. An alternative method of obtaining a curve of this general nature is to arithmetically average intercept values read from individual well curves. The error in principle of this arithmetical method is that each well does not contribute in its proper weight to the determination of a correct, or weighted, average. The method employed in this study was designed to properly weight the characteristics of each well into the rate of decline for an average well. The decline obtained in this method is called the weighted average rate of decline, referring to the decline in capacity with decline in pressure.

The general fact suggesting and validating the weighting method is, clearly, that in any combination of diverse elements, the component parts contributing to the correct average rate of decline must be weighted with respect to characteristics that are pertinent in determining that average rate of decline. An arithmetical average, in contrast, does not weigh diverse factors, and therefore, cannot be properly used to represent a mean when those diverse factors are contributory parts.

The wells are grouped by quadrants consistent with the system used in estimation of reserves. However, this was not necessary to the weighting method under which any grouping of diverse values may be used. The weighted curves for the average well and for total wells are the results of the study which are directly used. For this reason, and for the reason that the company has copies of individual well curves, the accompanying charts show only the weighted average rate of decline by quadrants and for the average of all wells, and the decline for the total groups of 92 and 97 wells.

The summary tabluation of quadrant data (Table I) has its columns numbered, and in parenthesis are noted in the columns and operation by which derivation is accomplished.

For this reason, no further discussion is provided, as it is believed that the method and procedure of determining the weighted average rate of decline will be clearly evident on inspection of the tabulation.

At this point we have established the rate of capacity decline with decline in pressure for all wells of the Canadian River Gas Company. This relation is shown by the curves of Chart I.

The remainder of the study deals with the availability changes anticipated for the future, coincident with pressure changes occasioned by yearly withdrawals. With the decline of pressure the existing wells will approach a point in capacity at which additional wells will be necessary to supply the maximum 24-hour demand.

From consideration of Canadian River Gas Company well pressures, it was determined that from 1939 to 1940 the arithmetical average rock pressure decline was 8.6 pounds, from 378 pounds to 369.4 pounds. The assumption of 378 pounds for 1939 is made on the statement of company representative that the build-up of wells, after taking the 1939 pressures, was such as to convince him that the average of 375 pounds of actual readings should be increased to 378 pounds. Using 375 pounds as indicated by Texas Railroad Commission data, the pressure loss between 1939 and 1940 would be 375 pounds to 369.4 pounds, or 5.6 pounds, for the amount of production involved. The choice of pressure loss, between 5.6 pounds and 8.6 pounds is very important, as it is a measure of pressure loss to be expected for future years for the volume of production involved. If the lower loss is taken, it is clear that the number of years to reach a given pressure, or open flow to supply a given load, will be larger than if the greater loss of 8.6 pounds for the 1939-1940 volume is assumed to be correct on the statement of the company. For the purpose of forecasting the decline of availability (Table II), 378 pounds is tentatively assumed to be the pressure for 1939. In so accepting this pressure, it is strongly emphasized that the results, in terms of open flow for future years and the time at which additional wells are indicated to be necessary, should be considered as a minimum and very conservative. That is $8.6\# \div 5.6\# = 1.54$

represents approximately the ratio of results to be obtained by using 5.6 pounds and 8.6 pounds for the 1939-1940 pressure loss. Using 5.6 pounds, the period before additional wells are necessary would be approximately 1.54 times that shown on the basis of 8.6 pounds loss for 1939-1940. This should be kept in mind when inspecting Table II, the forecast of availability decline.

Considering the production of 48,240,022 MCF for the year ending July 31, 1940, comparable to the times at which pressures are taken, the assumed pressure loss of 8.6 pounds gives a production of 5.61 billion cubic feet per pound. Dividing this production per pound into the annual anticipated load of 49 billion cubic feet, the indicated annual pressure loss is 8.73 pounds per year, 8.8 pounds being taken for the purpose of calculation of Table II. This pressure loss is for that part of the calculation involving 92 wells. The loss per year for 97 wells would obviously be lower as an increase in active size of reservoir would result in more production per pound less, or less pressure loss for a given volume. The ratio of this loss is assumed to be the ratio of the recoverable reserves for the 92 wells as against 97 wells. This is 96.9 per cent, giving a pressure loss per year for 49 billion cubic feet of 8.5 pounds on 97 wells. This loss is conservative the reasons that the 8.8 pounds' loss was explained to be conservative. The current annual production of Canadian River Gas Company is approximately 46 billion cubic feet. For the purpose of this study, it is assumed to be 49 billion cubic feet yearly, to provide for reasonable increase of load allocable to the Denver line requirements.

Due to the fact that pressures are taken by the Railroad Commission at mid-year and company records are kept for calendar years, it is necessary to convert the mid-year data to the end of calendar year. This was done by considering July 31 to be the mid-year point, and the mid-point over which pressures are taken. The five months to December 31 provides the 5/12 by which pressure drop between mid-year points is multiplied. This gives 374 pounds plus as an average for 92 wells, on the basis of using 378 pounds for mid-year 1939, which is very close to the 375-pounds average mid-year pressure if the Railroad Commission figures are strictly taken. Thus, for practical purposes, the mid-year

test data on basis of 375 pounds can be accepted as representing the end of 1939, on the basis of 378 pounds taken for mid-year 1939 as claimed by the company for reason of build-up. Any difference as small as a pound for the end of 1939 is of no consequence when pressure is converted ultimately to form P_t2 or the pressure factor $P_t2 - P_s2$, as the difference in value in this form represents an indistinguishable difference on the scale of Chart I or Chart II.

Refer to Table II, headed "Forecast of Decline of Availability—From Wells Existing and Producing December 31, 1939, and Supplemented by Existing Wells to Be Added in 1940." This tabulation is carried forward on the dual basis, one part for the 92 producing wells of December 31, 1939, and one part involving 97 wells which include two old wells to be connected and three new wells already drilled which are to be connected in 1940 or shortly thereafter.

Columns 1 and 2. These columns require no explanation.

Column 3. This column tabulates the total recoverable reserves at the end of the year, obtained for successive years by subtraction of 49 billion cubic feet per year. That part of the column for 97 wells differs from the figures shown for 92 wells in the amount occasioned by the addition of wells not hitherto considered. Since no production record exists for these wells which could be used as a basis for estimating recoverable reserves or expectancy, they were added on the basis of average of previously existing wells. The reserves figure for end of year 1939 was taken from a previously submitted exhibit entitled "Estimate of Recoverable Gas Reserves, Present Wells."

Column 4. This column tabulates the year and pressures for consecutive years resulting from the yearly pressure losses already described.

Column 5. Anticipated annual production of 49 billion cubic feet, subtractable from the recoverable reserves of 92 wells and 97 wells.

Column 6. Annual pressure loss for 49 billion cubic feet per year, obtained as already described.

The remaining columns tabulate data on a weighted basis derived from the first part of this study.

Columns 7, 8 and 9. The weighted well head pressures for 92 and 97 wells on which availability was calculated correspond to, but are not identical with, the pressures of column 4. Taking the end of year 1939 as an example, which, as explained, is for practical purposes the same as mid-year 1939 using the Railroad Commission data, the weighted formation of pressure P_f is 404.696 pounds. Subtracting the weight of gas, the weighted absolute well head pressure is 380.85 pounds, and the weighted well head gauge is 367.85 pounds. For succeeding years' value, 8.8 pounds yearly loss is consecutively subtracted. From these pressures is then determined the well head gauge, formation pressure, P_f and P_f2, which latter value is found on the weighted curve for 92 wells and the corresponding delivery capacity read on the horizontal scale of Chart I. Similarly, values for 97 wells for columns 8, 9 and 10 are determined.

It will be noted that the weighted well head pressures are about 6 pounds below arithmetical average gauge for 92 wells and about 6 pounds below for 97 wells. This variation in difference for 97 wells results from addition of new wells, which increased the weighted average P_f approximately one pound for the company's wells (Table I).

Column 10. This column is obtained by squaring the P_f values of column 9.

Column 11. This column represents delivery capacity read opposite values of column 10 and from the curves for total wells of Chart I and Chart II.

Column 12. This column is 25 percent of column 11. At this point, another conservative position assumed for this study should be noted. The curves are delivery curves indicating ability to deliver at the surface, and not absolute open flow curves indicating ability to produce a larger amount of gas at the sand face. Capacity in the sense here used refers to capacity to deliver at the surface.

Refer to Chart II on which the group curves of 92 wells and 97 wells of Chart I are repeated, but in a more separated relation for convenience in reading.

These curves, with their notations, are believed to be self-explanatory. On the right is indicated several yearly dates.

Next, reading to left, is indicated corresponding availability at 25 percent of capacity. Next, to left of the curve is the corresponding weighted average well head pressure, and farthest to left is indicated the number of years after 1939. Between the two curves is an auxiliary scale showing, as a matter of convenience, the weighted average well head gauge pressures corresponding to values of the pressure factor scale. To determine further the approximate arithmetical well head gauge pressure from the scale, it is necessary only to add 6 pounds when considering the 92-well curve, and 5 pounds when considering the 97-well curve. Every year was not indicated on the curves to avoid confusion. However, they can be identified on the curves by referring to Table II. The purpose of these curves is to indicate when 25 percent of capacity is incapable of supplying a maximum 24-hour delivery rate of 190 MMCF. This volume was adopted after finding that the maximum to 1940 was approximately 180 MMCF.

From inspection of Chart II and Table II, it will be noted that:

(a) For the 92 wells of December 31, 1939, 25 percent of delivery capacity does not decline to 190 MMCF or lower until after the close of 1957, or 18 years after 1939.

(b) For the 97 wells of December 31, 1940, 25 percent of delivery capacity does not decline to 190 MMCF or lower until after the close of 1959, or 20 years after 1939.

At this point it is again emphasized that assumption of pressure data as recommended by a company representative, as against pressures published by the Texas Railroad Commission, results in a more rapid pressure loss, open flow loss, and availability loss for a given volume of gas removed, and that acceptance of the 378-pound average for 1939 claimed by the company is an extremely conservative position to adopt in this study. Adoption of the 375-pound average for mid-year 1939 would give results which would be 1.54 times those under (a) and (b), that is 27 years for 92-well basis and 30 years for the 97-well basis, before additional wells would be necessary to supply a maximum 24-hour demand of 190 MMCF for the total Canadian River system.

The analysis of back pressure data for the dual basis of 92 and 97 wells of Canadian River Gas Company, as described, summarizes to the following conclusions:

For Weighted Average Rate of Decline of Weighted Average Well

	Basis	
	92 Wells	97 Wells
1. Weighted Average Capacity, 1939, MMCF	17.837	—
Weighted Average Capacity, 1940, MMCF	17.394	17.888
2. Weighted Average Closed-in Formation Pressure P_t, 1939 (Abs.)	404.696#	—
Weighted Average Closed-in Formation Pressure P_t, 1940 (Abs.)	399.040	400.265#
3. Weighted Average Closed-in Pressure at Well head, 1939, Gauge	367.85	—
Weighted Average Closed-in Pressure at Well Head, 1940, Gauge	362.53	363.68
4. Arithmetical Average Closed-in Pressure at Well Head, 1939	375.05	—
Arithmetical Average Closed-in Pressure at Well Head, 1940	368.3	369.4
5. Q value at 10 M Pressure Factor, 1939 and 1940, MMCF	2.339	2.375
Q value at 100 M Pressure Factor, 1939 and 1940, MMCF	12.440	12.693
6. "N" value or slope, 1939	.7256583	—
"N" value, or slope, 1940	.7256583	.7278999
7. Pressure Factor, 1939	163.779	—
Pressure Factor, 1940	159.233	160.210

	Basis	
	92 Wells	97 Wells
For Weighted Rate of Decline—Total Well Curves		
8. Total Open Flow, 1939, MMCF	1,671.90	—
Total Open Flow, 1940, MMCF	1,625.36	1,672.48
9. "Q" Value at 10 M Pressure Factor, MMCF, 1939 and 1940	218.93	234.00
10. "Q" Value at 100 M Pressure Factor, MMCF, 1939 and 1940	1,164.25	1,250.65

The weighted average and total group curves can be plotted from the above data, which can be identified on table and chart Nos. I and II made part of this exhibit. The curves are calculated from mid-year back pressure data for 1940. The 1939 pressures as reported by the Texas Railroad Commission were used to determine capacity on the 1940 curves. The pressures noted in these conclusions and on Table II should not be confused with the adjusted pressures used for end of 1939 and 1940 as explained in the section dealing with decline of availability.

11. At various future dates the wells will be capable of supplying maximum 24-hour demands as follows: (From Table II)

End Year	Years After 1939	Availability @ 25% Capacity 1 MMCF 92 Wells	97 Wells
1942	3	375.0	405.0
1947	8	307.5	337.5
1950	11	270.0	295.0
1955	15	213.75	237.5
1957	18	191.25	218.75
1959	20	168.75	192.5

12. For the 92 wells of December 31, 1939, 25 percent of delivery capacity does not reach a required maximum 24-hour delivery rate of 190 MMCF until after the close of 1957, or 18 years from 1939. From the standpoint of capacity, no additional wells are necessary until that time.

13. For the 97 wells to be connected in 1940 or shortly thereafter, 25 per cent of their delivery capacity does not

reach a maximum 24-hour delivery rate of 190 MMCF until after the close of 1959, or 20 years from 1939. From the standpoint of capacity of wells active in 1940 or shortly thereafter, no additional wells will be necessary for 20 years.

Attention is again called to the fact that this study is conservative by reason of pressure considerations previously explained, and that the interval before wells are necessary from the standpoint of capacity may be greater than stated by approximately one-half.

In working out this availability study to the point where it could be determined when additional wells were necessary, the calculations necessarily arrive at a definite year. The conclusion as to definite years is, in degree of importance considered secondary to the fact that that year is beyond what might be considered as a reasonable period of time. That is to say, the results of this study would still be entirely valid had the availability been so reduced as to indicate wells to be necessary at some earlier date but still beyond a reasonable period of time.

The tabulations and charts constituting part of this exhibit are listed below.

Table I. Summary—Analysis of Back Pressure Data—Construction of Weighted Average Rate of Decline.

Chart I. Weighted Average Rate of Decline Curves, by quadrants and for average of 92 wells, weighted decline of capacity with decline in pressure for total of 92 wells and 97 wells. This chart is illustrative of the data and calculations of Table I.

Table II. Forecast of Decline of Availability.

Chart II. Weighted Decline of capacity with decline in pressure, for total of 92 wells and 97 wells involved in the dual basis of the study. On these curves are indicated various periods of time, to the point where the wells concerned will reduce in capacity so that 25 percent of that capacity will not supply a maximum 24-hour rate of 190 MMCF. The curves of this chart are illustrative of the data of Table II.

The Trial Examiner: Do you have another question of Mr. Stevens, Mr. March?

Mr. March: Yes.

Q. Mr. Stevens, you stated I believe here that the back pressure curves and data for 1940 for individual wells used in the calculation of weighted rates of decline, were supplied by a representative of the Canadian River Gas Company?

A. Yes.

Q. What do you mean by that?

A. As to the representative, Mr. Watson supplied those curves and they constitute Exhibit 97, I believe, and by the curves themselves, I mean that those were stated by Mr. Watson to be identical with similar curves in the office of the Texas Railroad Commission and were curves built up from data taken in company—or under supervision—in company with or under supervision of both the Canadian River Gas Company and the Texas Railroad Commission.

In short they are the 1940 back pressure tests and curves taken by the Railroad Commission and the Canadian River Gas Company.

Q. And in so far as individual wells are concerned you just adopted those curves of the company?

A. I have, yes.

Q. All of which are found in Exhibit 97?

A. Yes.

Mr. March: That's all.

Cross Examination

By Mr. Spencer:

Q. Mr. Stevens, what do your working papers consist of in connection with this exhibit?

A. They consist of rather extensive calculations, Mr. Spencer, which are summarized there.

Q. And I assume your working papers will be available to our representatives for checking?

A. As far as I am concerned, with the concurrence of counsel.

Mr. Spencer: Does counsel have any objection to that?

The Trial Examiner: Mr. Stevens' working papers I presume will be made available?

Mr. March: They will. They will be made available. When do you want them?

Mr. Spencer: Not right at this moment. That is all for the present. I wish to reserve cross examination on this exhibit.

The witness further testified with respect to pressure drop on Canadian River wells as related to production, which is tabulated as follows: (Vol. 86, pp. 12953-12954:)

Year	Production for Each Pound Lost in Pressure
1937-1940	11.13 billion cubic feet
1938-1940	8.156 " " "
1939-1940	6.619 " " "

The witness further testified on redirect examination (Vol. 86, pp. 12953-12963) as follows:

By Mr. March:

Q. You have stated several times here in answer to questions, Mr. Stevens, that you were conservative here. Now, I will ask you why a pressure drop of 8.8 pounds a year is conservative. Can you illustrate just how it is conservative?

A. Yes. Considering the Canadian River production on three different bases; first, the last four years including 1937, 1938, 1939, 1940, the pressure decline, 16.4 pounds, in those four years from 385.8, to 369.4, an average decline per year of 4.1 pounds for a volume of 37,383,940,000 cubic feet—strike out that relating to 37 billion—the accumulative production comparable to this pressure drop for this period was 182.508 billion. Dividing by the 16.4 pounds pressure drop, we get a figure of 11.13 billion per pound. Reducing all this and following examples to a common basis of 49 billion so that the pressure drop is comparable in all those cases, we divide in this first instance 49 billion by 11.13 billion which gives a pressure drop per year for that period of 4.4 pounds decline.

Speaking of 49 billion, that is comparable with the 8.8 that was used.

Taking the last three years, using 1938, 1939 and 1940—do you want me to read all these figures, or, rather, give the answer? If you want to shorten the record— .

Q. Answer the question the way you see fit. In other words, you better give the figures so that opposing counsel will have an opportunity to see what you have done.

A. The pressure decline in those three years from 386.065 to 369.4, a pressure decline of 16.65, or an average decline per year of 5.555. The volume produced during that time was 135,912,842,000 cubic feet which divided by the pressure drop for the period of 16.665 gives 8.156 billions per pound which in turn divided into 49 billion is 6.008 pounds per year on the 49 billion basis as against the 8.8 pounds used.

Through 1939 and '40, the last example, comprising two years, the pressure drop from 383.37 to 369.40, a difference of 13.97 pounds, corresponding to that was the production of 92,464,196,000 feet, which divided by 13.97 gives a production per pound of 6.619 billion, which in turn divided into 49 billion to obtain the yearly pressure loss on the basis of 49 billion, gives 7.4 pounds per year as compared with the 8.8 used, and that I think illustrates what I meant by conservative, in so far as any other logical grouping undertaken in this kind of study shows a lesser pressure drop than I do assign to Canadian River acreage.

Q. Now, Mr. Stevens, there has been a great deal of discussion here as to what would be the effect upon your study if the production had increased, if your production requirements and the company's requirements were increased considerably in the years to come. Have you made a study of what would be the effect on your study if certain contemplated increases were made or certain increases in production requirements were necessary?

A. Yes.

Q. Now, will you tell me there how long it would be before Canadian River would have to drill any wells? Have you got that figured out? How would the production have to go into that drilling of wells?

A. Basing on 1939 and 1940, the yearly loss in pounds would change if increased rates per year were withdrawn—increased volumes per year, and figuring down to 197 pounds, the point at which the system will fail to supply 190 million cubic feet, I realize that there is a combination both of increase in takes and increase in peak load, predicated for the company, but referring to the most recently stated peak of

190 million—well, I see we are getting into difficulties, because that was claimed to be on a 16.4 pounds base, but at any rate, to illustrate this, if we take 50 million a year it will be 18.78 years before the present wells would not be able to supply the peak loads.

Q. You mean would be unable to supply it?

A. The time at which it will be unable to supply it, and taking the 52 billion which was outlined, I believe, in Mr. Beardsley's exhibit—59 million exclusive of demands of the line as yet unbuilt to Milwaukee, 52 billion per year, it would be 18.06 years before it will be unable to supply 190 million cubic feet per day.

Q. From what day is that?

A. From the end of 1940.

And going up, with a considerable jump, to 60 billion a year, it will take 15.65 years before 190 million per day cannot be produced by the present wells.

Going up to 70 billion it will be 13.41 years, and going up as an extreme to 80 billion, it will be 11.74 years after 1940, which is in this latter instance certainly more than the seven years of the period from 1940 to 1947.

I realize that this 190 million peak load, if it is 16.4 base, these yearly figures which I have read, to convert that 190 million to 14.65, the periods stated would need to be divided by 1.119, to obtain the answers on the basis of approximately 203 million cubic feet. I don't check that 208, Mr. Keffer. If you are really talking about 190—

Mr. Keffer: I was not talking about 190, Mr. Stevens. It was 186, I believe—yes, 186, on 16.4 base, as your 1940 peak.

The Witness: I beg your pardon. 208 million, that should be revised to, and the previous references to 190 million should be changed to 186 million.

Mr. Keffer: The 190 million was with your 14.65 figure.

The Witness: Yes.

Mr. Keffer: You probably became confused or probably I did.

The Witness: At any rate, that corrects it to the proper basis in terms of your stating 186 million was a 16.4 figure.

Mr. Keffer: That's right.

By Mr. March:

Q. Does that complete your answer, Mr. Stevens?
A. Yes.

Mr. Keffer: May I interject just one question there?

Mr. March: Certainly.

Mr. Keffer: In increasing your volumes which you spoke of, you failed to increase your peaks also, didn't you, Mr. Stevens, in the answer you just gave?

The Witness: As a matter of fact, I think I stated practically an absurdity when I stated 80 billion per year. I have not increased the peaks accordingly. To increase those peaks beyond a certain point of the capacity of the line obviously requires extensions of the pipe line system and they will not, if I understand the situation correctly, increase greatly beyond—or if at all—beyond the present 186 million on the 16.4 base without extensions to the system.

Mr. Keffer: You are talking about the Denver line?

The Witness: No, I am talking about the entire system, including the—that was the peak of the entire system.

Mr. Keffer: That's all.

By Mr. March:

Q. Now, Mr. Stevens, there has been some questions raised here by Mr. Keffer as to whether or not you did not know that the pressure decline per production was accelerating from year to year—Canadian River Gas Company wells. In other words, that the production was going down per pound loss.

Now, I want to know if you had plotted on your Exhibit 182 the 1940 figure, whether that would have shown that the pressure had declined more in 1940 than they did in 1939.

Mr. Spencer: Before you answer, we object to that, Mr. Examiner. If it is going to be evidence, let's have it plotted. Let's see what it is so we can cross examine on it.

Mr. March: You can see what it is, but Mr. Keffer asked the question as to whether or not—time and time again—

whether he didn't know that the pressure declines were accelerating over the years, and I want to find out whether or not in 1940 the pressure decline was greater than in 1939.

Mr. Spencer: Well, I don't object to your doing any of that except this: I don't want you to speculate on what would happen if he had done so. Let's see what it is and get it in the proper form so that we will be able to cross examine on it.

The Trial Examiner: Has he done that, Mr. March?

Mr. March: Yes.

The Trial Examiner: Ask the witness the question.

By Mr. March:

Q. Have you plotted your 1940 figure on your Exhibit 182 curve there?

A. A bit of explanation I think is necessary there in that it must be remembered that in Exhibit 182 the calculated curve on the basis of a ratio was the Canadian River curve. This differs in this respect, that the Canadian River data was used, and the data then so plotted was investigated with respect to the last several years to see what the incline or decline or decrease or increase in the—it was checked with regard to the last few years to determine the changes indicated in the pressure volume or the pressure production trend and that is about the simplest way to describe it.

Q. Does that differ from the factors you used in calculating your curve in Exhibit 182?

A. It varies in this respect, that it is plotted on the Canadian River data alone without any reference to contiguous areas of production.

Mr. March: In view of that fact, Mr. Spencer, I will not ask the question. If I do I will prepare an exhibit on it.

Q. But you can answer this question: Do you know whether or not in 1940 the pressure declines on the Canadian River wells was in excess of 1939?

A. I will answer your question in this way: The 1938, 1939, taken by itself—

Mr. Spencer: Now, just a minute, Mr. Stevens. Let's be careful, Mr. March, because if you get started here you

are going to require a lot more cross examination. You haven't laid any foundation for that particular question.

Mr. March: Oh, yes. The question was asked my witness whether or not he did not know that the decline was accelerating on Canadian River wells. I have a right to ask him a question now as to whether or not he has gotten evidence to show that it was not.

Mr. Keffer: Mr. March, I predicated that on Mr. Watson's figures which was the basis of his exhibit here, and he said on the basis of those figures "yes." In fact, the question has already been answered, favorably, to my mind.

Mr. Spencer: Why don't you save that question?

Mr. March: The question was asked my witness and it is a redirect question. My witness was interrogated on this matter on cross examination.

The Trial Examiner: Read Mr. March's question, will you please, Mr. Reporter?

(The question referred to was read by the reporter as set forth above.)

The Witness: There was not in excess—

Mr. Spencer: Wait a minute. We have made an objection to the question.

The Trial Examiner: Did you make an objection?

Mr. Spencer: Yes. I thought we did. I beg your pardon.

The Trial Examiner: The objection will be overruled.

By Mr. March:

Q. Answer the question, Mr. Stevens. They weren't in excess, you say?

A. They weren't in excess of the production established by 1938 and 1939.

Q. Were they as much?

A. No. I was going to answer that in a graphic sense; that is to say, if you consider the trend established by 1938 and 1939 the curve will have a steeper incline than the curve similarly drawn with respect to 1939 and 1940 and is one of those cases typical of what you might expect over a period of years, where one year may be a little low and

another year a little bit high, and making it necessary to consider them all as a group rather than with respect to consecutive years when you are calculating an amount of gas out per pound or vice versa.

That is due simply to inaccuracies or lack of buildup, any one of which reasons are impossible to determine quantitatively.

Q. So instead of an accelerated decline in 1940 you have a less decline in 1940 than you did in previous years?

Mr. Keffer: He didn't say that.

The Trial Examiner: Just a minute, Mr. March. He didn't say that.

Mr. March: Do you object to me asking that question? You say he didn't say that?

Mr. Keffer: You asked a leading question.

Mr. March: You object to the leading question?

Mr. Keffer: Yes.

Mr. March: Is the objection sustained?

The Trial Examiner: Now, read this question back again, please, Mr. Reporter.

(The question referred to was read by the reporter as set forth above.)

The Trial Examiner: He hasn't said anything like that, Mr. March.

Mr. March: Well, he can state whether he did or not, Mr. Examiner. I understood that he did. I understood that that was the point.

The Trial Examiner: If you understood that, then why ask that question? Do you just want to rehash it?

Mr. March: I want to clinch it.

The Trial Examiner: Well, let the record speak for itself on that.

WATSON, witness for Canadian, testified with respect to the arithmetical average pressure of Canadian River wells

and the 1939 and 1940 buildup prior to the taking of the pressures (Vol. 30, pp. 4205-4208) as follows:

Q. You were asked to get the average rock pressure decline for all wells for the past three years. Do you have that information now?

A. Yes, sir.

Q. That is for the years 1938, 1939 and 1940?

A. Yes, sir.

Q. Will you give that, please?

A. Those are numerical rock pressure averages.

Q. You took the number of wells and averaged them?

A. In 1938 the arithmetical average rock pressure was 383.5 pound gauge; 1939, as I have previously testified, the average rock pressure was 375 pounds. That was a test made in mid-year 1939 as recorded and reported on that day. When I made my 1940 rock pressure report I found additional pressures taken after the date of the 1939 report reflected that the 375-pound rock pressure was lower than it should have been since all of the wells had not been shut off for any sufficient length of time. I, therefore, revised the 1939 rock pressure, arithmetical rock pressure, to 378 pounds as observed after the mid-year 1939 report.

Then in 1940 the rock pressures officially observed by the Railroad Commission were 370 pounds.

Q. What was that figure?

A. 370 pounds.

Q. Do you consider that that figure of 378 pounds for 1939 is a more accurate reflection of the pressures obtaining in mid-year 1939 than the one you had previously given?

A. Yes, that is as I have previously explained: If you get the increased pressures after you have made certain observations you have to consider the whole report, and obviously, 375 pounds was too low or I could have never gotten 378 pounds two or three months later.

Q. You attribute it to the fact there had not been sufficient shut-in on some of your wells on the pressures that gave the 375-pound average?

A. That is correct. Several of the wells were not shut in at all and we had no rock pressure on them at the time of the mid-year 1939 report.

Mr. Lange: I wonder if that same thing is true with reference to the 1940 test?

The Witness: No. In the 1940 test the Railroad Commission gave us advance notice that they were going to run the tests. The back pressures must have good rock pressure or they wouldn't work at all, so we had two or three months notice and we worked out a schedule with them as to which well we would test on certain days. By having that schedule we shut off wells in a sufficient length of time ahead of the test to get what we were satisfied was good rock pressure.

Mr. Lange: How long were they shut in for the test?

The Witness: Not less than a week and longer if we could spare the wells. I think it was approximately a week.

By Mr. Keffer:

Q. Right in that connection, Mr. Watson, it may not be clear to someone reading the record who doesn't know the practical operating angle of a gas well: When you produce a gas well at the end of the line, your working pressure on that well is lower than what you refer to generally as the rock pressure, is it not?

A. Certainly. It couldn't deliver gas if it didn't.

Q. If you have a 400-pound rock pressure well after it had been closed in long enough to build up and you started operating that well, its working pressure might be fifty pounds or less than its normal rock pressure, might it not?

A. It must be less than its rock pressure.

Q. Then if you operate that well for a period of time and we go out to that well today while it is in operating condition and close off the line and gauge its rock pressure, you wouldn't get a normal rock pressure?

A. Certainly not.

Q. What would you get? Would it be sub-normal?

A. Most certainly.

Q. Then the practice in taking rock pressures is to shut the wells in for a sufficient length of time that the wells will build up to what might be determined their normal rock pressure, is that correct?

A. Our practice has always been to shut a well in and observe the pressures at intervals of a day or two days or whatever we think is necessary until two consecutive observations have shown no material increase, and when I say "material increase," I mean a tenth of a pound or so, which we are now able to gauge.

STEVENS, Commission Witness, further testified (Vol. 90, pp. 13652-13656) as follows:

Q. Mr. Stevens, I hand you a diagram entitled "Pressure Versus Cumulative Production, Exaggerated Scale, Canadian River Gas Company Wells, Panhandle Gas Field, Texas," and I will ask you to state what that purports to be.

A. That is what it is.

Mr. March: I will ask that it be marked for identification.

The Trial Examiner: It will be marked for identification as Exhibit No. 263.

Mr. Spencer: Exhibit 263, Mr. Examiner?

The Trial Examiner: Yes, Exhibit 263.

By Mr. March:

Q. Mr. Stevens, I notice you have Charts A and B, indicating the same title on each one, is that correct?

A. Yes.

Mr. March: Mr. Examiner, may we have Chart A marked as Exhibit 263-A and Chart B marked as 263-B?

The Trial Examiner: Very well.

(Exhibits 263-A and 263-B, Witness Stevens, marked for identification.)

By Mr. March:

Q. Will you state briefly what these two charts show?

A. The purpose of this exhibit is to show the effect of addition of 1940 data when applied to the pressure-cumulative production data of immediately preceding years of Canadian River Gas Company wells.

Chart A: Chart A is drawn on an exaggerated scale so that the relation of yearly points may be exaggerated and clearly seen.

Curve A, referring to Chart A, of course, is drawn with respect to 1938 and 1939 to show the trend established by those years alone.

Curve B is drawn with respect to 1939 and 1940 to show the trend established by those years alone, and to illustrate

the fact that 1940 data tends to establish the trend of Canadian River wells at a higher level. Curve B also establishes the fact that by reason of its higher position on the chart that the company's wells are not suffering an accelerated rate of decline. Curve B is drawn as indicated with consideration to the average pressure of 97 wells.

The average pressure for these wells is slightly higher than that for 92 wells, this number excluding three new wells drilled in 1940 and 2 old wells which were to be connected in 1940 or soon thereafter.

Curve C is drawn with respect to 1939 and 1940, as was Curve B, but giving consideration to the average pressure of 92 wells. What has been stated in comparing Curve B with Curve A can be said in comparing Curve C with Curve A. The difference in the two comparisons is, one of degree by reason of the lower average pressure of 92 wells already mentioned, and apparent from inspection of Curves B and C relative to Curve A.

Curve D: This curve drawn solid is an average curve drawn with respect to 1938, 1939, and 1940. It does not actually touch the three yearly points. It passes 1938 and 1939 at equal distances and between the two 1940 points; that is, for points represented by the average on 92 wells and on 97 wells, it approximately equals distances from them.

To have drawn the curve near the 92 well point for 1940 would have changed the medial relation with respect to 1938 and 1939. In short, the curve is believed to be properly drawn with respect to all three years. It could with substantial logic be drawn in a closer relation to the 1940 point for 97 wells as that is the number of wells for 1940.

Going to Chart B, the curve on this chart is Curve B of Chart A, using a less exaggerated scale so that the curve may be extended to intersect with an assumed abandonment pressure of 25 pounds, that intersection being at 2895 billions of cubic feet. Subtracting the production to 8-1-40 of 220.5 billions of cubic feet, the reserve recoverable for the 97 wells is 2,374.5 billions of cubic feet.

Further subtracting production of 48.07 billion for the year ending 8-1-40, we arrived at 2326.43 billion as the re-

serves which can be recovered from the present wells as of 8-1-39, using Canadian River wells alone. The figure on the basis of projection of Canadian River data alone is comparable with the recoverable reserve of 2,186.7 billion in Exhibit 182 determined by another method.

It is not the purpose to displace the figure for the reserves to be recovered as shown in Exhibit 182; however, the opportunity is taken to observe that the reserve figure for that exhibit is conservative on the basis of Curve B which was drawn with the effect of 1940 production contained therein.

The essential purpose of this exhibit is to show the effect of 1940 data for company wells. Its effect as indicated by Charts A or B is to influence the pressure-cumulative trend to a higher level. In doing this it is indicated that the company's wells do not have an accelerated decline in pressure.

Stevens also sponsored Exhibits Nos. 263-A and 263-B, which are as follows:

Exhibit No. 263A

CHART A

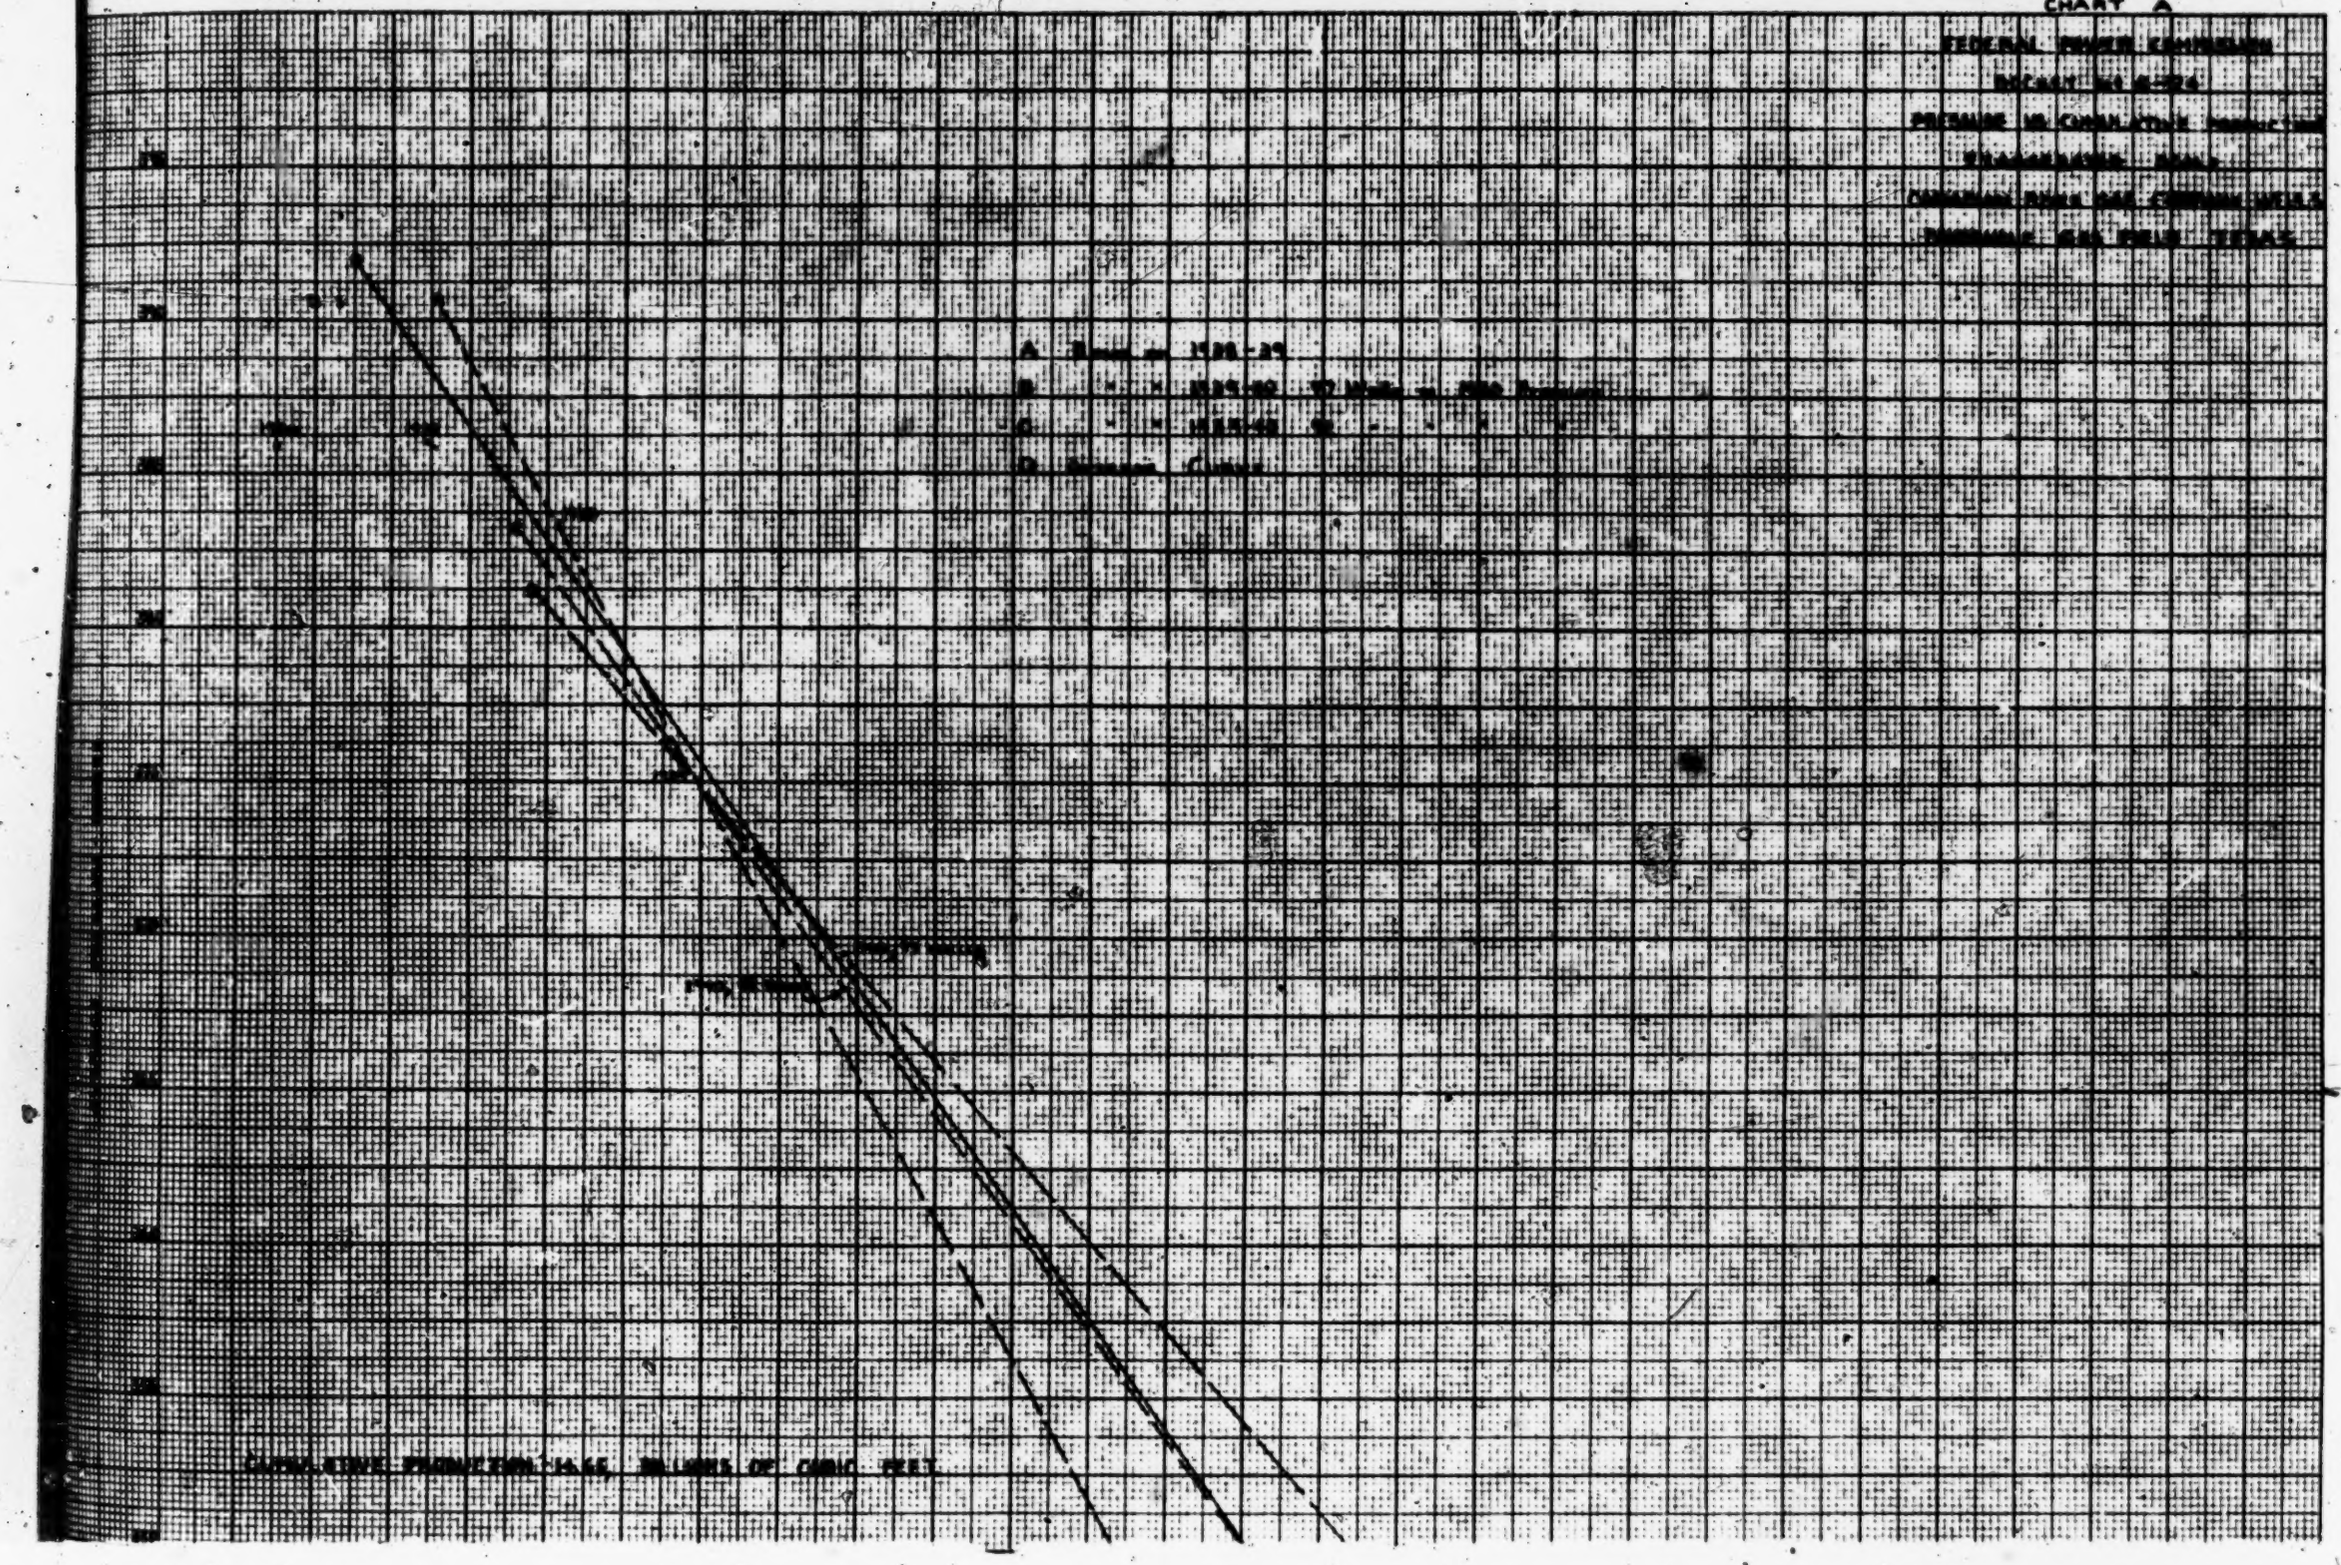

CHART B

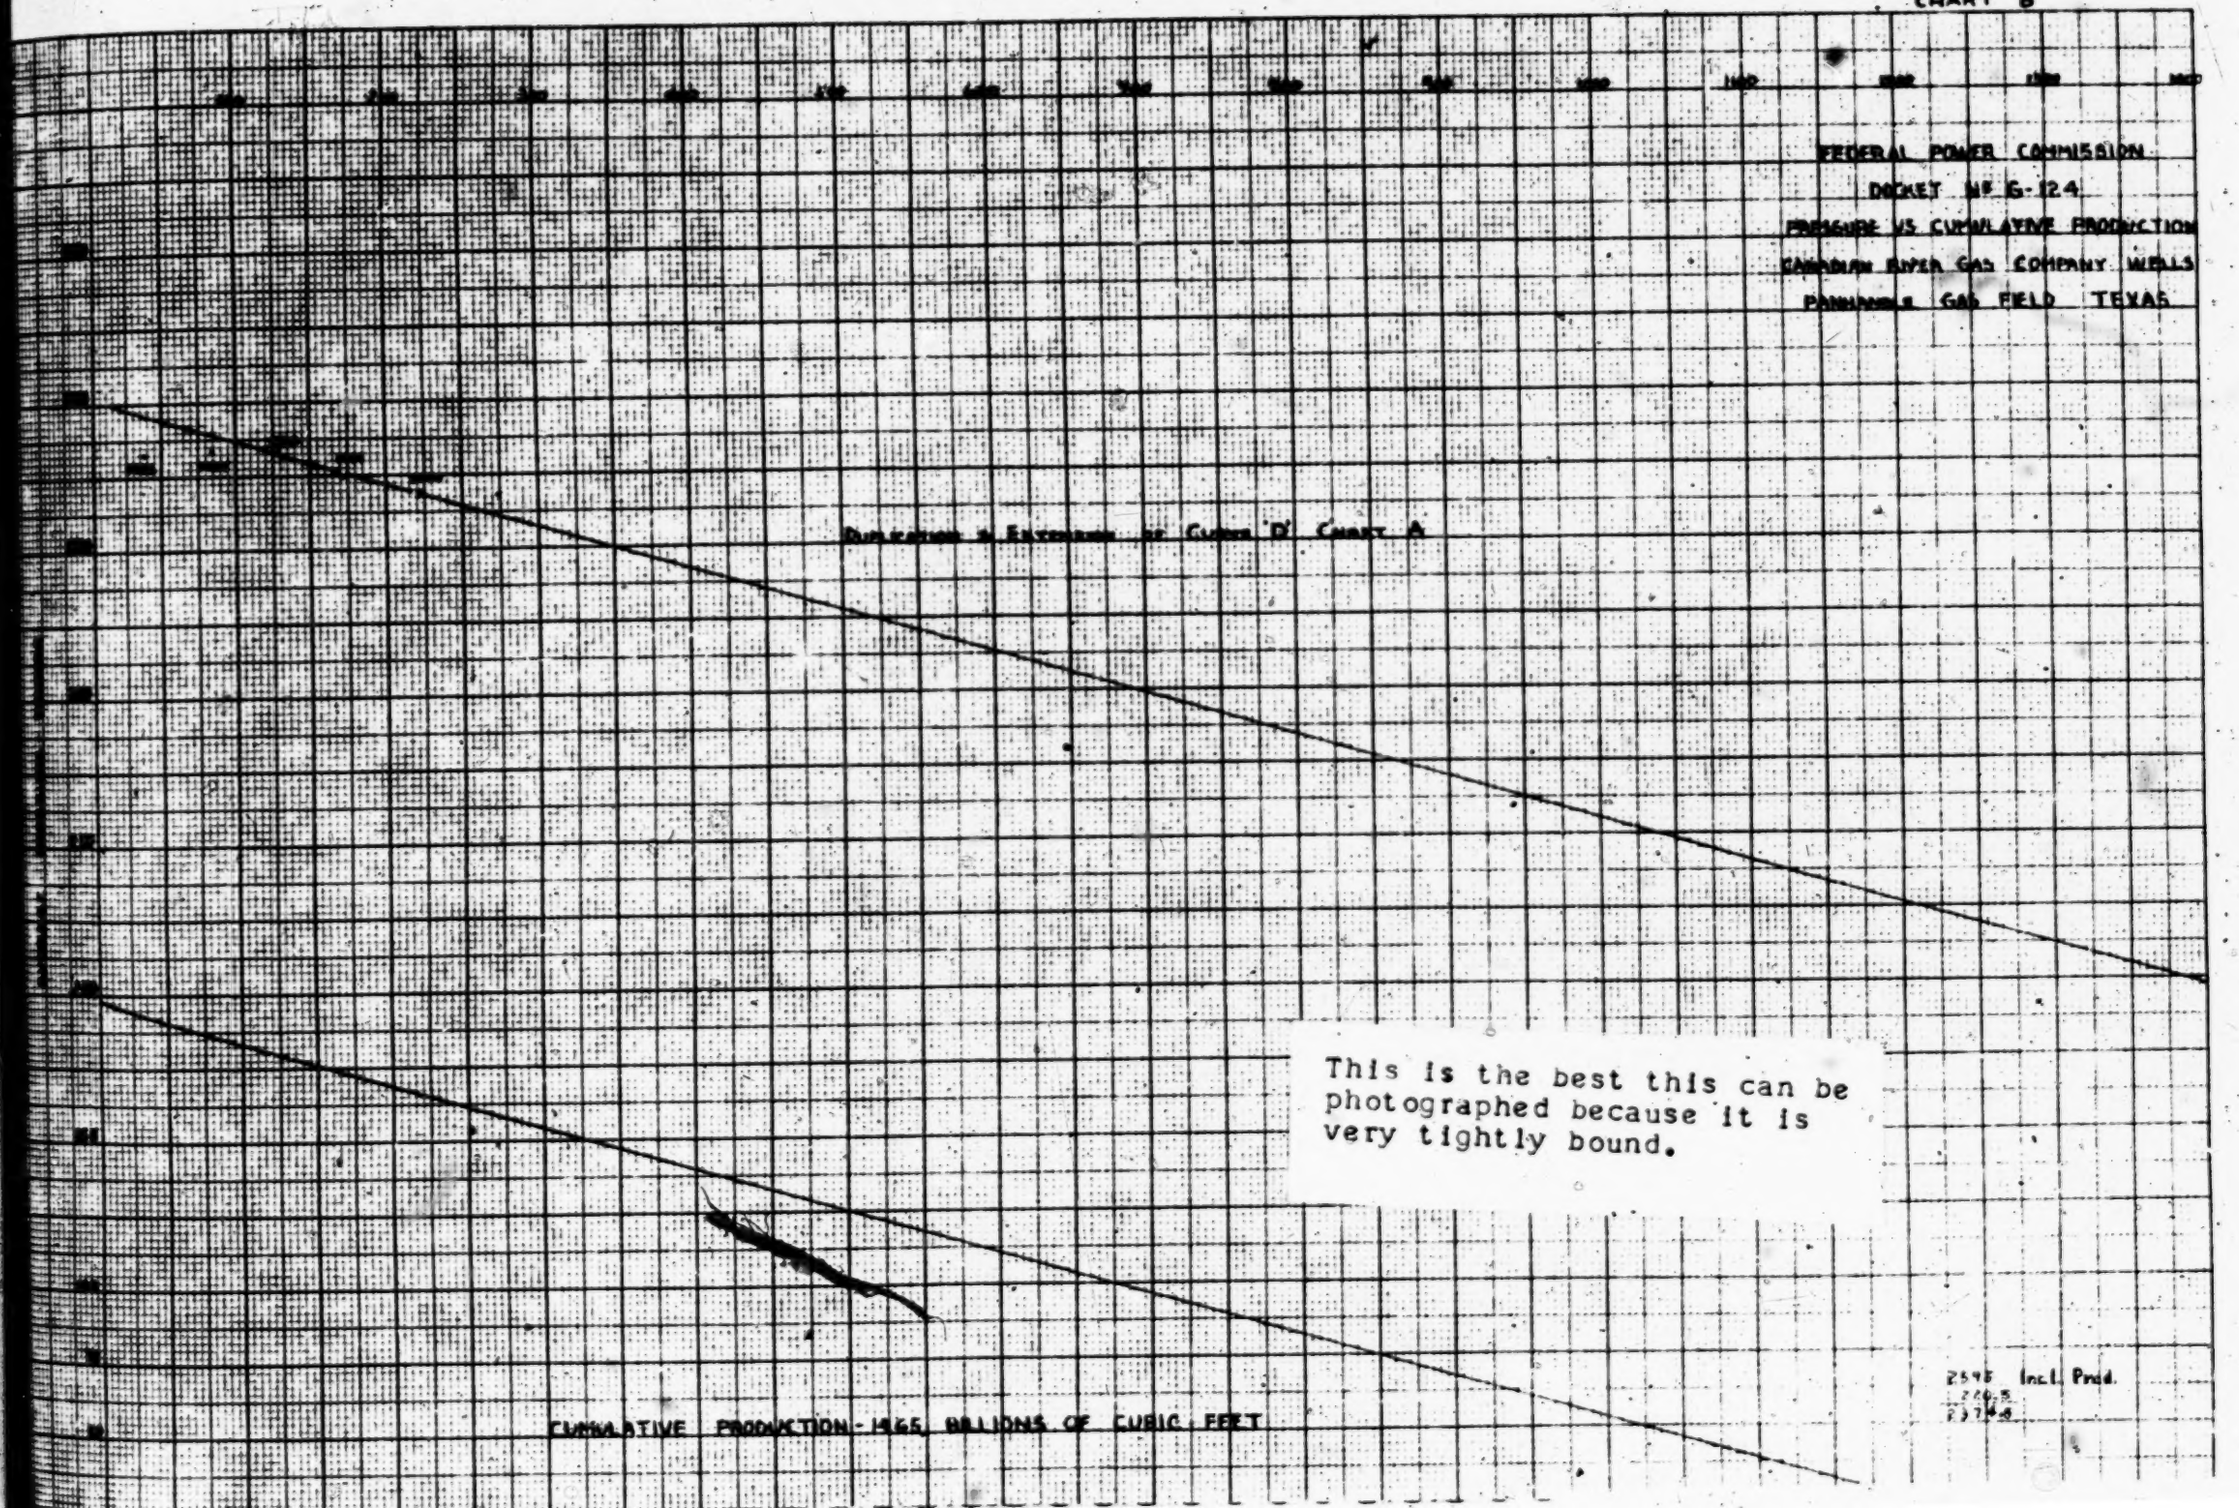

This is the best this can be photographed because it is very tightly bound.

Stevens further testified on cross examination (Vol. 95, pp. 14649-14678) as follows:

He stated that he had sponsored Exhibit 182 in which he had used the arithmetical average of certain wells in order to get the estimated producing ability of those wells, and in arriving at that arithmetical pressure average for that exhibit he took into account the wells owned by companies other than Canadian River Gas Company, but all of which were located within the quadrants outlined by Mr. Hammer in which Canadian River had gas acreage, with the exception of Quadrant 3 in Hutchinson County. He took into account only the southwest corner of that quadrant. He took into account many other wells other than the Canadian River wells in arriving at the arithmetical average of pressures for the purpose of determining the volume of gas Canadian River wells would produce.

Stevens also sponsored Exhibit 197, which was an availability study in which he predicted the decline in rock pressure from year to year as to Canadian River Gas Company wells which was also based upon an arithmetical average of the rock pressures of such wells, but in that exhibit he didn't follow the same course he had followed in Exhibit 182, but with respect to Exhibit 197 he took into account only the wells that were actually owned by Canadian River Gas Company.

Witness also sponsored Exhibit 252 which was an availability study but limited to some 55 wells which are furnishing gas to the Denver pipe line, and in that study he considered the arithmetical average rock pressure of those wells only.

Stevens also sponsored Exhibits 263-A and B, which consist of some curves which purport to show the arithmetical average pressure of various Canadian River wells from 1938 to 1940, inclusive. Exhibit 263-B merely projects such curves into the future.

The witness does not recall the type of wells that he included in his arithmetical average in Exhibit 182, but which were not included in Exhibit 263-A and B, 252 or 197. He stated there was no point in knowing that as it wouldn't have made any difference what kind of wells they were.

In constructing arithmetical averages shown on Exhibit 263 the witness indicated the 1939 arithmetical average of Canadian River wells as being 375.05. This was not the same pressure that was used for the year 1939 in the construction of his Exhibit 197.

Watson had previously testified that the arithmetical average pressures of Canadian wells for 1939 was 378 pounds and this was the figure used in Exhibit 197, and when constructing Exhibit 197 he recognized Watson's testimony to this effect. He stated this gave him a more conservative answer with respect to Exhibit 197. He stated, however, that when he came to prepare Exhibit 263-A he felt perfectly justified in using a different figure, 375.05, because this was the Railroad Commission pressure figure. He stated also that Mr. Watson had furnished no proof that the accurate arithmetical average pressure was 378 in 1939. He stated also that he could not raise the 1939 pressure as utilized in Exhibit 263-A and B without also increasing the 1938 and 1940 pressures by 3 pounds, and if he had done so the result would have been just the same in so far as his curves are concerned.

The witness was then asked if it was not obvious that there was no reason why 1940 should be changed. His answer to that was that there was no obvious reason, either, from the Railroad Commission as to why 1939 should be changed.

The witness further testified (Vol. 95, pp. 14660-14667) as follows:

Q. Let's take them one at a time. I have started with 1940. Now, so far as you know, there is no reason on earth to change 1940 up or down, is there?

A. The same is true of 1939.

Q. Can you answer yes to that question? There is no reason?

A. I see no reason at the present time other than indicated. I see no reason at the present time not to take the 1940 pressures as shown by the Railroad Commission for the wells involved in the 1940 point, and I also see no reason why the 1939 should not be considered in the same way.

Q. All right. Now, Mr. Watson—or, the Canadian River

Gas Company does have a different figure for 1939 than the reported Railroad Commission figures?

A. I don't know what they have. I know what they reported to the Commission but other than that I have seen no Canadian River reports.

Q. You have heard Mr. Watson's testimony?

A. He is confident that the buildup should be three pounds higher than recorded by the Railroad Commission.

Q. Didn't he go a little further into that?

A. I don't recall.

Q. Didn't he say a test was made a month later where the well was permitted to build up and showed actually three pounds more?

Mr. March: I object: The record will speak for itself.

Mr. Keffer: He is quoting Mr. Watson here and has predicated his exhibit upon it.

The Witness: I don't remember his testimony as to the month showing three pounds. As I recall his testimony, he was convinced that the 3-pound buildup was necessary but I don't believe he stated any figure other than three pounds.

By Mr. Keffer:

Q. As a matter of fact, Mr. Watson—if he testified there was actually a 3-pound buildup following the time that the Railroad Commission took their pressures, isn't that some proof that the pressures for 1939 were three pounds higher than what the Railroad Commission records showed?

A. To do that, all of the wells would have to be out of service.

Q. Do what?

A. All of the Canadian River wells would have to be out of service.

Q. To do what?

A. To continue the buildup you referred to.

Q. What kind of a buildup did I refer to?

A. What kind did you refer to?

Q. You're telling me. Go ahead.

A. If you have this buildup I referred to, the three pounds, it would be necessary to have the wells out of service in whole or in part.

Q. Is that such an impossible thing in the summertime?

A. Well, it is not an impossible thing, of course.

Q. Do you know how to take rock pressures, Mr. Stevens?

A. Certainly.

Q. How?

A. Is it necessary to explain that?

Q. It ought not to be but isn't it a common practice where they can do so to permit the wells to build up? Isn't that the desired thing?

A. Yes.

Q. Is there any reason on earth why wells can't be shut in ahead of the person gauging the wells so they can build up? In fact, isn't that the ordinary normal and customary way to do it?

A. Yes, a certain number at a time.

Q. Then those wells could have built up three pounds just as Mr. Watson said they did?

A. After the date of the tests, you mean?

Q. Yes.

A. It is possible. There has been no evidence submitted to that effect or any claims made that—

Q. Do you consider Mr. Watson's sworn testimony as evidence in this case?

A. He did not specify individual wells which had built up.

Q. Is it necessary to specify as to individual wells to make the statement that he got a three pound higher average pressure?

A. No.

Q. It is still a fact, isn't it?

A. That probably isn't necessary to be specified. I will take his word for it if he made a dependable statement.

Q. You make the statement here that in 1939 the pressure was 375 pounds. I don't see where you have listed any wells.

A. I can show them to you.

Q. How's that?

A. I have them listed here and I can show them to you.

Q. I am sure you can. I am also sure Mr. Watson could do the same thing, yet you wouldn't want me to disregard your testimony here because you haven't enumerated the wells, would you? Would you?

A. It would be a rather difficult thing—

Q. What's that?

A. It would be a rather impossible to enumerate the wells, Mr. Keffer.

Q. I know it is. The only point is, when you have testified that it was 375 pounds on that particular date that is sufficient to prove that it was 375 pounds, even though you haven't referred to a single well.

Mr. March: I object to the line of questioning. He is arguing a legal point.

The Trial Examiner: I think that is true, Mr. Keffer.

Mr. Keffer: That is perfectly all right. I will withdraw the question; however, Mr. Stevens started the argument.

The Trial Examiner: Perhaps we can go along better if—

Mr. Keffer: I think we can.

Q. As a matter of fact, Mr. Stevens, if the pressures actually were 378 pounds in 1939 instead of 375 pounds, then in the interest of preciseness which you mentioned a while ago, that is the figure you ought to have used?

A. With this provision, that 1938 be also increased and 1940 be also increased in the same amount. As a matter of fact, it isn't definite in a case of the two other years as to how much they should be increased.

Q. All right, let's see. We are increasing 1939 from 375 to 378 because there was an error. There was no error in 1940. Why change 1940 simply because you have corrected 1939?

A. Well, this sureness of error as to 1940 probably isn't described as an error but an inaccuracy. In the case of 1939, if you had a buildup as your sworn testimony indicates, of three pounds—you state that in 1940 there was no discrepancy due to any degree of shut-in. I don't believe that lack of discrepancy of three pounds or any other pounds in the case of 19[illegible] has been established.

Q. As I understand you, then, there would be no reason to change 1940 simply because you corrected 1939, is that correct?

A. I tried to say in so many words that there is no reason that I know of why you should not change 1940 if you changed 1939.

Q. Let's go back all over the thing again. Why are we changing 1939, Mr. Stevens?

A. Under the assumption that this statement of 3 pounds later buildup is an entirely valid one.

Q. All right, there has been no such contention made on the 1940 rock pressures, has there?

A. There hasn't been any that I recall.

Q. Then if we correct 1939 for the reasons you have just stated, there would be no occasion to make any change in 1940, would there, because the same reason doesn't apply?

A. If the reason does not apply in 1940, that would be true, but I haven't seen any substantiation of that point of view.

Q. What point of view?

A. That 1940 was perfect.

Q. You haven't heard anybody question it, have you?

A. Well, the 1939 pressure, as quoted by the Railroad Commission, wasn't questioned and all of the people that have read the pressures in the country and used them, if they have used them, haven't questioned them, either. It is a question of specific disagreement which one of your representatives has claimed to be the case.

Q. Naturally it would be assumed to be correct until it is shown to be to the contrary. I would do that and you would do that.

Mr. March: I object to that. That is a legal conclusion.

Mr. Keffer: There is no such a conclusion to that question, Mr. March.

Mr. March: As a matter of fact, that is merely a legal question. As a matter of fact, Mr. Stevens has already said that—

Mr. Keffer: All right, all right. Mr. March, I'm trying to save time but I might get to a point where I don't care to save time. Let's go on.

Q. What we always want is a correct figure, isn't that true?

A. I believe so, yes.

* * * * *

Stevens further testified (Vol. 95, pp. 14667-14693) with respect to the pressures of certain wells for various years. His testimony, in part, is tabulated as follows:

	1938	1939	1940
Bivins A-21	391	356	386
Killgore A-1	485	384	
Masterson J-1	409	367	396.2
Bivins A-4	385	356	398.6
Bivins A-23	415	343	365
Masterson D-4	388	365	377.5
Masterson F-1	415	413	404.5

The witness stated that he had made some corrections with respect to Killgore A-1 and Masterson F-1 wells due to the fact that a representative of the Railroad Commission had told him that a correction should be made.

The witness then stated that the drop in pressure on Bivins A-21 well from 1938 to 1939 was 35 pounds, and from 1939 to 1940, there was an increase of 30 pounds, and that this indicated quite clearly to him as a gas engineer that there was something wrong with the 1939 pressure, and indicated that the 1939 pressure, in all probability, was taken without an adequate buildup, and that the 1940 pressure was taken with an adequate buildup.

He also referred to the pressure of the Masterson J-1 well and stated that the decline from 1938 to 1939 was 42 pounds and that there was an increase from 1939 to 1940 of 29 pounds, which indicated that there was an improper buildup in 1939 on that well. He referred also to the Bivins A-4 well, and stated that this well had lost 29 pounds in pressure from 1938 to 1939, but had a buildup from 1939 to 1940 of 42 pounds, and that this indicated that something was radically wrong with the 1939 test on that well.

Witness referred also to the Bivins A-23 well, and stated it had a drop in pressure from 1938 to 1939 of 72 pounds but had increased from 1939 to 1940 22 pounds; that the Masterson D-4 well had decreased 23 pounds from 1938 to 1939, but increased 12 pounds from 1939 to 1940.

The witness was then asked whether, if Mr. Watson had told him there had been an improper buildup for the 1939 pressure survey and had cited as examples some of the wells above-referred to, that would have been sufficient to incline the witness to accept the sworn testimony of Mr. Watson that there had been an improper buildup. The witness an-

swered that he didn't see any particular reason why he should doubt Mr. Watson's veracity or question it."

The witness also stated that the taking of arithmetical averages of wells is not a perfect process, and that where the pressures are averaged arithmetically they may throw you off either up or down depending upon whether the additional wells that are drilled from time to time are drilled in high or low pressure areas, and that as a matter of fact, Exhibit 263-A illustrates this very point. The plat shows the 1940 pressure for 92 wells as being approximately 369 pounds, but when he added the 5 additional wells drilled in 1940 and included these with the others, his average for 1940 was about 370 pounds. He stated that if 5 additional wells were drilled in an area in which the pressures were 400 pounds or above, that this would increase his average pressures for 1940 about 1½ pounds, even though there had not been any production from or drainage into or away from the area.

Stevens further testified (Vol. 95, pp. 14680-14681) as follows:

Q. So you could expect in taking arithmetic averages of wells where you are drilling them from year to year a fluctuation?

A. That is one thing that would cause a fluctuation of point from a straight line, yes.

Q. As a matter of fact, most of the Canadian River's undrilled acreage is in higher than average pressure bands, isn't it?

A. Well, you made quite an example once of this Thompson well, I believe that was.

Q. As Canadian River drills wells from time to time, the drilling of those wells will have a tendency to hold that arithmetical average up to a greater extent than it would have been if they hadn't drilled wells?

A. That is true. You also drilled three new wells in 1939 that would have that effect.

Q. All right.

A. You have three new wells in 1940 which had a parallel effect.

Q. So you can't rely too strongly on arithmetic averages, can you?

A. For what purpose?

Q. For any purpose.
A. Not for meticulous accuracy you cannot.
Q. How's that?
A. Not for meticulous accuracy.

The witness further testified that he did not take the average of all of the wells in the entire quadrant as Mr. Hammer did and as Stevens did in his Exhibit 182 because he wanted to show the conditions on Canadian River's acreage with respect to production versus pressure and exclusive of the contiguous areas.

He stated that in his Exhibit 182 where he considered the additional wells in the various quadrants, the problem was to determine the gas that was going to be produced from Canadian wells alone, and that it was necessary to include contiguous areas because this method involved a ratio and he got this ratio by taking into account all of the other wells. He stated that the same general objective in Exhibit 263-A and B were the same as in Exhibit 182, but that he had simply used a different method. He was then asked that if he was right in Exhibit 182, whether he was wrong in Exhibit 263-A and B, or vice versa, and he answered,

"No, just a simple degree of conservatism."

He stated that if he had taken into account all of the other wells which he did consider in Exhibit 182, he did not know whether the rock pressure would have been less or not because he hadn't made that comparison, but he did say that the rock pressure should be less in that case because, as he recalled it, the wells not considered were in generally lower pressure areas, but he did not know definitely whether all of them without exception were in lower pressure areas than the Canadian wells which he counted or not. He did say, however, that in any event the other wells had no bearing on this Exhibit, and he did not have any concern as to whether they were higher or lower. He said that the wells he did consider were affected by whatever occurred adjacent to them, and in that sense the adjacent areas were to some indeterminate degree incorporated in the study, but that he would make no attempt to evaluate them.

He stated that the effect of the other wells were taken

into account in a different way, but that it was an ultimate conclusion they can never be determined or evaluated.

Witness Stevens further testified (Vol. 96, pp. 14785-14799) as follows:

Q. In Exhibit 182 you have assumed that every time Canadian River drilled a well it increased its available supply of gas by 23 or 24 billion feet?

A. Not specifying the exact area.

Q. I know, but in order to reach that conclusion you had to assume that each well had its own drainage area, didn't you?

A. It is inconceivable to think a well doesn't have some drainage area.

Q. Can you answer my question as to whether or not it had its own drainage area?

A. It had a drainage area unspecified.

Q. Mr. Stevens, on your theory a well that has no production should have no pressure drop, is that right?

A. If it isn't depleted.

Q. If it isn't producing it hasn't started to drain, has it?

A. If it isn't interfered with locally by contiguous areas, that would be the case.

Q. What would you say would be a contiguous area? How far away would a well have to be?

A. That is an indeterminable thing, depending upon physical factors of the formation.

Q. Would you say four or five miles?

A. I wouldn't say any miles.

Q. Do you know where the Masterson B-5 well is?

A. Yes, I do.

Q. The closest well to it is about 2½ miles, is it not?

A. Yes.

Q. And the wells in the other direction will range from four to five miles away, isn't that right?

A. That looks about right.

Q. Would you expect that well to suffer any drop in pressure in the absence of production?

A. It might. As a matter of fact, I believe it did.

Q. Yes, as a matter of fact, it suffered eight pounds drop from 1939 to 1940, didn't it?

A. That is right.

Q. That had to be from a complete buildup in both years, didn't it?

A. Yes, that is right.

Q. There couldn't be any mistake on that pressure in buildup or lack of buildup, could there?

A. I don't think so.

Q. That is because it hadn't produced any gas in that year's buildup. In fact, it hasn't drained any. That is rather conclusive—you do know there was no production from it, don't you?

A. I believe that is the case.

Q. Will you check and see if that is the case?

A. Yes. That is Bivins B-5?

Q. No, Masterson B-5, Quadrant 1, Potter County.

A. I am fairly certain from my recollection, that well isn't connected—it is to be connected and hasn't been.

Q. You don't show any production for it, do you?

A. No.

Q. It is pretty good proof it didn't have any, isn't it?

A. I think so.

Q. That well dropped eight pounds, and eight pounds, strange as it is, is the very average you used on these computations, isn't it?

A. On the average?

Q. On the average.

A. That is right.

Q. So that well is an average well in pressure drop without a cubic foot of production, isn't it?

A. Well, that may be coincidental.

Q. May be what?

A. It may be coincidental. Go ahead.

Q. Will you answer my question?

Mr. March: What is the question?

Mr. Keffer: Read it.

(The question referred to was read by the reporter as set forth above.)

Mr. March: It is obvious the average is the average of the drop.

The Trial Examiner: He hasn't answered it yet. If he would say "yes, that is merely a coincidence," that would have answered the question.

The Witness: That is a coincidental check with the average of 8 pounds.

By Mr. Keffer:

Q. Now, Mr. Stevens, if you would take that well certainly as a test, you could have the 8 pounds pressure drop on Canadian River acreage without a foot of gas, couldn't you?

A. Repeat that question, please.

(The question referred to was read by the reporter as set forth above.)

The Witness: As a test? What kind of a test?. What do you mean by test?

By Mr. Keffer:

Q. As the basis for the comparison.

A. And consequently from that specific well you say that production has no relation to pressure drop, is that what you mean?

Q. You just answer my question. It doesn't matter what I mean. The question is very simple and it is susceptible to a simple answer.

A. It has declined eight pounds without—that is in how many years?

Q. One year.

A. One year?

Q. Yes, that is what you said, wasn't it? If it isn't, check and see if it isn't one year.

A. I don't recall—regardless of what number of years it is, I do not have the pressure for 1939 on this sheet here.

Q. It is 408-400 pounds.

A. All right, I believe I recall that.

Q. How's that?

A. It declined eight pounds in one year without any production.

Q. All right. It is evident Canadian River acreage might suffer an 8-pound drop without any production at all, isn't it?

A. That criterion you apply is unreasonable. It is unreasonable for the reason that while this well has drained eight pounds in one year without production, as you say.

the rest of the wells had some production from them, didn't they?

Q. Yes, surely.

A. Well,—

Q. Let's get a little more specific here. The drainage area of that well is determined by drawing a concentric line around it and splitting the difference between it and opposing wells and would be something like 30 or 40 square miles, wouldn't it?

A. Whatever it is makes no difference as the fact is no two wells have to have the same drainage area. The fact that Canadian River took gas out of the surrounding wells, nearby wells, regardless of whatever the distance was—if it went four miles in their case, all right; if it went a mile and a half or two miles to the nearest wells, okay—doesn't mean every well is going to do that.

The reduction of pressure by movement of gas is still a relationship that can't be denied. That gas that went from under the Masterson B-5—we will assume it came out of Canadian River wells—served to increase the amount of production. If you had taken it out of the Masterson B-5 the wells that had gotten it would have shown a lesser amount of gas per pounds, so you end up in this average at the same point. That is the difference?

Q. All right, let's rush along here. It does show unquestionably that the drainage distance of a well in that area is several miles, doesn't it?

A. It indicates that it is at least 2½ miles in that case to the nearest well but that doesn't say anything about the rest of the wells in the field.

Q. You wouldn't assume it would run down one little groove to that one particular well, would you?

A. I am making no assumption as to the character of flow.

Q. And it is especially true when that well 2½ miles away had a pressure that was very little lower than your Masterson B-5 well and the wells to the north and northeast created a differential, you would assume it went to the north and northeast?

A. It doesn't make any difference where it went.

Q. That well does indicate most clearly that all of these

wells owned by other companies within the Canadian River block and those others we named offsetting it have a very distinct bearing and relationship upon the producing life of the Canadian River property?

A. If you base it upon the performance of the B-5 well, that is true, but whatever the effect is—I have repeated it so many times—in the pressure volume record of Canadian River Gas Company it is indicated on Exhibits 263-A and 263-B.

Q. The pressure records for other wells are not in there, are they?

A. No, but the effect is upon the Canadian River.

Q. How do you know?

A. You were claiming they reduced the pressure of the Canadian River.

Q. That is right. Do you agree to that?

A. That is what you are claiming.

Q. Do you agree to that?

Mr. March: In regard to what well?

Mr. Keffer: I am not talking about any particular well.

Mr. March: In regard to what area?

The Trial Examiner: We will stand in recess until 2:00 o'clock.

(Whereupon, at 12:35 o'clock, p. m., a recess was taken until 2:00 o'clock, p. m., of the same day.)

Afternoon Session, 2:00 P. M.

The Trial Examiner: The hearing will be in order.

Whereupon, HARRY F. STEVENS, the witness on the stand at the time of recess, having been previously duly sworn, resumed the stand and testified further as follows:

Mr. Keffer: Mr. Reporter, will you read back the last few questions and answers before we recessed?

(The record referred to was read by the reporter, as set forth above.)

Cross Examination (Continued)

By Mr. Keffer:

Q. Do you agree to that?

A. I think I'd better have the question restated more definitely, if I may.

Q. You had made the statement that I was assuming or evidently assumed or took the position that the other wells we were discussing would affect the Canadian River wells as a result of drainage and I asked you if you agreed to that.

A. Oh, you were referring to contiguous acreage, I believe.

Q. And blocks within our acreage as well, which is not owned by us.

Mr. March: You are asking him now whether or not he thinks those wells are draining your acreage?

Mr. Keffer: Whether those other wells are draining our acreage.

Mr. March: I object to that. This is not a drainage exhibit and has nothing whatsoever to do with it. It is a study of individual wells of the Canadian River Gas Company and the peak performance of those individual wells.

The Trial Examiner: The particular question, though, I believe, Mr. March, is relevant to the exhibits. The objection will be overruled.

The Witness: I don't say that those wells are draining Canadian River acreage or that they do not. I have not made a study of drainage with respect to that. If they are, as stated before, their effect is in the production data of the Canadian River.

Mr. Keffer: I'm sorry, Mr. Stevens, I thought I was listening but I didn't get your answer.

(The answer referred to was read by the reporter, as set forth above.)

By Mr. Keffer:

Q. How is it in the production data?

A. If it is in there it is reflected in the decline of pressure, if that is the case. If they drain to Canadian River, they are reflected in the maintenance of pressure.

Q. Well, then, you would have been on the safe side if you had counted them in in arriving at your arithmetical averages, wouldn't you?

Mr. March: Which exhibit are you talking about?

Mr. Keffer: Where he shows his arithmetical averages, Exhibit 263-A and B, as well as 252. It would apply to both of them as they weren't considered in either one.

The Witness: I don't see as it is necessary. They are already in there.

By Mr. Keffer:

Q. Well, you haven't taken down their pressures and averaged them in with the pressures of Canadian River wells, have you?

A. No, but it is certainly clear that whatever effects that they had affected the Canadian River pressure.

Q. And you assume that whatever that effect is that it is right now fixed and is not going to change?

The Trial Examiner: I think he has answered that, Mr. Keffer.

Mr. Keffer: Yes, I think he has.

Q. All right, now, Mr. Stevens, you stated some time back; that is, this morning, that although your calculations are based upon the assumption that each well on the average would decline the same as every other wells in pressures, yet you knew as a matter of fact that that would not be the case actually. Is that the case?

A. Yes, that the average is the thing that applies. You are assuming in this case here that where we went through wells and showed on the basis of an 8.3, or approximately 8 pounds per year, the working pressure required would be—

Q. As you have stated in your exhibit, Table 3?

A. The gauge working pressure would be more than the rock pressure. You are assuming that they would have to decline that 18.26 pounds in those two years. The meaning of the average year is not that at all. Some of these wells which on your basis you say will decline 18.26 per year, it may well be that that well will decline six pounds or ten pounds or five.

Q. Yes, and it might decline 40 or 50, might it not?

A. Well, that is rather an extreme.

Q. Well, it might decline more than the 18.26, isn't that correct?

A. It isn't very likely.

Q. Well, you have your average at 18.26, you're bound to have some that are more than that, aren't you?

A. That's just the point. Some are more and some less.

Q. And your answer is that they might decline more than 18.6?

A. That's right, and the overall average gives you this margin we referred to.

Q. You do say that is going to vary from year to year according to the actual decline?

A. Depending on how much you take from it.

Q. And then if they are going to vary from year to year, then your average will vary from year to year, necessarily, won't it?

A. No. You are talking about individual wells.

Q. I know, if individual wells aren't going to decline on the average basis, then you have got a different factor each year to figure a different average each year.

A. The average will decline approximately eight pounds on the basis of the record.

Q. I say, I know that is what you say. Now, my point is, if the individual wells will vary from 18.26, then you would have to strike a new average each year to get your correct average, wouldn't you?

A. You still overlook the fact that this 8.8 pounds is that average.

Q. I understand that. That was the average—

A. That doesn't change.

Q. That was the average based upon your pressure figures of 1939 to 1940, wasn't it?

A. 1938, 1939 and 1940.

Q. All right, 1938, 1939 and 1940. All right now, if those individual well performances are going to vary, then as a matter of fact, your average is likely to vary.

A. Not materially, no, if any, on the basis of this record.

Q. How do you know it won't?

A. On the basis—

Q. How do you know it won't? How on earth are you going to tell that your average is going to be the same?

A. On the basis of three years history.

Q. Well, I don't think that answers the question. You say that on the basis of the record of your history it is not going to obtain in the future except on an average?

A. That's the story. That's all there is to it.

Q. Yet you say the decline is not going to be uniform, don't you?

A. It probably won't. It hasn't been, with respect to a given well.

Q. That's right. Well, your average is composed of all of your wells, isn't it?

A. That's right, and it, taking in to consideration those variations, has done so.

Q. Now, if your individual wells will differ, why wouldn't you have to strike a new answer each time?

A. My answer is the same as before.

Q. All right, if you think you have answered it.

On your exhibit 252 you have a type of weighting on that, haven't you?

A. Yes, sir.

Q. You weight your rock pressures with your open flows, don't you?

A. Yes.

Q. All right, then, it all depends on where that variance is going to come, doesn't it?

A. That is taken care of in the method.

Q. Let's see if it is. Now, you have got a weighted average, as you term it, as set out in Exhibit 252 where you have weighted your rock pressure declines or your rock pressures with your open flows. Now, to maintain that average you have got to have the same proportionate decline in the big wells as you have in the little wells, haven't you?

A. The effects of those open flows in terms of their respective curves from which they are read, one from each well, is weighted into that average. That, of course, is one reason why the weighted average isn't the same as the arithmetical average.

Witness Stevens further testified (Vol. 96, pp. 14870-14833) as follows:

Mr. Stevens was referred to his redirect examination with respect to Masterson B-5 well and stated that since that well had been shut in he would think it had a perfect build-up, but he didn't know whether the pressure readings were accurate or not.

Mr. Stevens further testified that the Allison Canadian

River well had a pressure drop of 9 pounds from 1939 to 1940, with a production of 73 million cubic feet, or a pressure drop of 1 pound for each 8 million cubic feet of production, and that the Bivins B-3 well in the same area had a 4 pound pressure drop, with 452 million cubic feet of production, or a production of approximately 113 million cubic feet for each pound lost in pressure.

Thompson A-2 well of Canadian had a production of 269 million cubic feet from 1939 to 1940, with a drop of 11 pounds in pressure, which resulted in about 24 million cubic feet of production for each pound lost in pressure, while the Thompson P-2 well, in the same area, and for the same period, had a pressure drop of 3 pounds, with production in excess of one billion cubic feet, or a production of approximately 360 million cubic feet for each pound lost in pressure.

The Masterson A-1 well for the same period produced 813 million cubic feet of gas, with a pressure drop of 6 pounds, which resulted in a production of 125 million cubic feet for 1 pound lost in pressure, and the Read A-1 well of Canadian in the same area had a production of 125 million cubic feet of gas, with a pressure drop of 12 pounds, or about 10 million cubic feet of production for each pound lost in pressure.

The Bivins A-5 well of Canadian had a production during the same period of 697 million cubic feet of gas, and lost only 1.4 pounds in pressure, while the Seay A-1 well nearby had a production of 104 million cubic feet during the same period with a drop in pressure of 7 pounds, or approximately 15 million cubic feet for each pound lost in pressure, and the ratio in favor of the Bivins well over the Seay well was in excess of 40 to 1.

The witness Stevens further testified (Vol. 96, pp. 14882-14883) as follows:

When you have a pressure decline in a well from one year to another of some 50 or 60 pounds with a certain production, we'll assume for the sake of the question 2 million feet, and the next year that well has a production of one million feet, on the theory that you have been expounding here for the several times that you have been on the witness stand, you would expect a decline in that subsequent

year of half of the decline you got in the preceding year, wouldn't you?

A. We are getting into this average again.

Q. No, I'm not talking about average at all. I'm talking about those wells Mr. March asked you about on redirect when you said or intimated pretty strongly, if you didn't say it, that it was a decline in production that caused those wells to build up.

A. To allow them to build up from their immediately surrounding areas to an indefinite extent. That certainly was a factor in allowing the pressure to build up.

Q. When they were on production with substantial volumes of gas?

A. Certainly. While there may have been substantial volumes of gas, there were greatly reduced volumes of gas.

Q. Are you changing your theory on the relationship between production and drop in pressure?

A. Not on the average.

Q. Just on some wells? Where you want to get a different answer you change?

A. It is simply an explanation of why those wells increased in pressure. It was due to a decelerating rate of production.

Q. Isn't the logical answer that a decelerating rate of production instead of increasing the pressure would simply decelerate the loss of pressure on your theory?

A. Well, it would depend on how bad the heavy production of the previous year pulled it down.

Q. All right, let's drive a peg there and stay right there until I ask you this question: Then in those previous years those wells didn't have a proper buildup, did they, before the pressures were taken?

A. That is illustrated by 1938 and year 1937 points on these curves.

Q. Will you answer my question, please? Those very wells didn't have that proper buildup for taking the 1939 pressures, did they?

A. That would seem to be the case.

Mr. Keffer: All right. That's all. You said that the first time and then you changed it. That's the only reason I went back into it. That's all.

The witness further testified that the pressures shown

on his graph in Exhibit 263-A and B were not weighted pressures. He further stated that if a field is fully developed you can take arithmetical averages and determine production with reference to pressure drops without using a weight medium which brings all of the acreage into account, and in such case an arithmetical average of the pressures of wells will enable one to make an estimate of reserves without any sort of weighting. He stated, however, that the Panhandle field was not fully developed and that the Canadian River acreage was not fully developed. He did state, however, that he could take arithmetical averages as to Canadian River wells and determine the recoverable gas from existing wells, which is all that Exhibit 263-A and B pretends to be.

Referring to the excess of available working pressure over line requirement, the average excess for 1942 and 1947, respectively, is approximately 86 pounds and 44 pounds, and represents the margin of well head working pressure over what is necessary at that point for the conditions of flow of wells totaling 130 MMCF into the lines and with 250 pounds at Bivins station. Having in mind the basic assumption of 250 pounds suction at Bivins, it is indicated that in 1942 and 1947 each well has a margin of both capacity and working pressure. It is also indicated by reason of this excess that 250 pounds suction can be maintained at Bivins station through 1947, that it will not fall to 150 pounds or any point between 150 and 250 pounds before that time. It then follows that no additional compression units are needed before 1947 except as may be dictated by the requirements of 250 pounds suction and the pumping of 130 MMCF.

In 1942 the available suction pressure at Bivins, of 250 pounds, will be 68.55% of the average rock pressure of 364.69 pounds to be expected at that time. In 1947 it represents 77.02% of the average rock pressure of 324.6 pounds expected to exist at that time.

It is my opinion that the foregoing investigation, on the basis of factual data more accurately forecasts the operating conditions than Mr. Rhodes' 'judgment figure' of 150 pounds suction pressure for 1943 and his conclusion as to

the necessity of additonal compressor capacity which is incidental to that judgment figure.

Also Mr. Rhodes' claim that suction pressures of one third or one half or one quarter of average closed in well pressures, said to exist in his experience in other fields, is not applicable to the Panhandle field when investigated with respect to Panhandle wells and company facilities which determine operating pressures.

The witness Stevens further testified (Vol. 96, pp. 14855-14861) as follows:

By Mr. March:

Q. Mr. Stevens, turn to your Exhibit 263-A and B.
A. Yes.
Q. I refer you to your 1940 point there.
A. Yes.
Q. Do you recall yesterday there was some effort to cite you several wells in which pressures had been increased in an effort to cast some doubt upon the accuracy of the 1940 point?
A. Yes.
Q. There were several of those wells mentioned and I believe you stated at the time that those pressures possibly increased because there might have been something wrong with the measurements. Did you during last evening examine the production of those wells in an effort to arrive at some answer as to why the pressure increased?
A. Yes, I have.
Q. I refer you first to the Bivins A-21 which was mentioned. Will you give me the 1939 pressure?
A. 356.
Q. Will you give me the 1939 production?
A. 385.7.

Mr. Keffer: Over what period?

Mr. March: I asked him to give me the 1939 production.

Mr. Keffer: I know that but we have calendar years and mid-years. I want to know which one it is.

The Witness: These are mid-year endings.

By Mr. March:

Q. I will ask you to give me the production of that well in 1939.

A. It was 2,326,909,000.

Q. That much what?

A. Cubic feet.

Q. Now give me the 1940 pressure.

A. That was 385.7, as stated.

Q. Which was an increase over 1939?

A. Yes.

Q. Give me the 1940 production from that well.

A. It was a production which was approximately half of the previous year, 1,361,611,000 cubic feet.

Q. Now let's take the next well. The next well was the Bivins A-14, was it not?

A. Yes.

Q. The 1939 pressure on that well was what?

A. 405.

Q. The production on the well in 1939?

A. 2,658,205,000.

Q. The pressure on the well in 1940?

A. That was 100.5 pounds.

Q. And the production in 1940?

A. That was 1,618,706,000 cubic feet.

Q. The next well is the Killgore A-1. Give me the 1939 pressure on that well.

A. 384.

Q. The production?

A. 1,024,778,000.

Q. The pressure?

A. 372.7 for 1940.

Q. And the production in 1940?

A. 1,024,326,000 which is almost exactly the same as the previous year.

Q. During that period the pressures did decline for that well?

A. They did decline. That was the one about which the area was discussed.

Q. Let's take the Masterson F-1. Will you give me the 1939 rock pressure on that well?

A. 413.

Q. And the production in 1939?

A. 128,772,000.

Q. The pressure in 1940?

A. 445 pounds.

Q. And the production in 1940?

A. 94,504,000.

Q. The next one was the Bivins A-23. Will you give me the pressure for it in 1939?

A. 343.

Q. And the production?

A. 324,170,000.

Q. And the pressure in 1940?

A. 365.2.

Q. The production in 1940?

A. 202,226,000.

Q. In other words, the production in that year was less than half of what it was in the previous year 1939?

A. That is right.

Q. Let's take the Masterson D-4 which was mentioned by Mr. Keffer. What was the pressure in 1939?

A. 365 pounds.

Q. The production in 1939 was what?

A. 3,094,794,000.

Q. The pressure in 1940?

A. 377.5.

Q. And the production in 1940?

A. 1,700,736,000.

Q. Roughly in percentage what was the decline in production in 1940 over 1939?

A. Not quite half.

Q. Now let's take the Bivins F-1.

A. 350 pounds in 1939; as for the production, 66,845,000.

Q. And in 1940?

A. 346.

Q. Pressure?

A. Yes.

Q. The production in 1940?

A. 532,615,000.

Q. I see. Now, Mr. Stevens, do you know of any other wells whose pressures increased in 1940 in the Canadian River Gas acreage?

A. Aside from those listed yesterday by Mr. Keffer, I did find one here, Bivins A-10, which in 1939 had a pressure of 382 pounds; production, 5,022,000. In 1940 it had a pressure of 390.8 with a production of 6,599,000.

Q. Are there any others that you ran across?

A. There is the Thompson B-1, which in 1939 had a pressure of 362 and a production of 16,887,000; for the following year 1940 it had 364.5 pounds for the production and 32,813,000.

Q. There may be others for all you know?

A. Well, I checked them quite carefully but I might have missed some.

Q. You might have missed some?

A. I doubt it.

Q. After looking at the production from these wells, is it not quite possible that the decrease in withdrawals from those wells might have had something to do with the increase in pressures in those wells in 1940?

A. That seems the case. I believe in every case that we have noted—it may not have been in every case, but at least in a majority of the cases the increase in pressure was accompanied by a rather strong reduced proportion of production. The amount of volume isn't the final criterion involved because one well might be able to produce larger amounts than another, whether or not the same pressure drop, but in general those lists represent cases where build-up was observed with greatly reduced rates of production.

Q. Now, Mr. Stevens, if it should be the case that all of those wells Mr. Keffer read off where the pressures are increased, the reason they showed an increase was because of erroneous gauging of the well or taking of the pressure, and is it not equally likely that the Masterson B-5 well where the pressure decreases and there wasn't any production, that might have been an error? In other words, one is—

A. Where there is an error—of course, it would be hard to determine that.

Q. You haven't made a study to find out whether it is an error or not, have you?

A. No, naturally, I don't see how I could check whether the Railroad Commission made an error in their figures or not.

Q. However, you have checked here in two years where there were errors in the mimeographed copy?

A. In one year, 1939.

Q. And two wells.

A. Those were called to my attention. In a sense, I didn't—they were checked after being brought to my atten-

tion. I don't know whether you would call it my checking it as the Railroad Commission checked it.

Q. And the officials of the Railroad Commission told you those two figures for those two wells you discussed this morning were wrong?

A. Yes, and Mr. Peterson adopted the same corrections.

Testimony of C. J. PETERSON

Witness for Canadian.

C. J. PETERSON, witness for Canadian, testified to various matters relating to gas reserves. His testimony in this connection (Vol. 68, pp. 9924-9944) is as follows:

A. "My name is C. J. Peterson. I was born in 1885 in the Hawaiian Islands and am a resident of Amarillo, Texas.

"I received my high school education in the Hawaiian Islands. I received the degree of A. B. in the Department of Geology and Mining at Leland Stanford University in 1910. My studies at Stanford University were entirely geological and engineering as related to mining and were specalized in economic applications of geology. Geological courses embraced both mining geology and petroleum geology.

"Since leaving Stanford University my entire career has been devoted to economic work in the application of geology.

"In 1910 I took a position with Tonopah Mining Company of Nevada as assistant mining engineer. My work with this company was underground surveying, sampling of ore bodies, drafting, estimations of reserves of ore bodies and reports of examinations on mining properties.

"In 1912 I went down to Venezuela as geologist for the New York and Bermudez Company, which was a subsidiary of the Barber Asphalt Company.

"At that time the Barber Asphalt Company and its subsidiaries had concessions of approximately five-sevenths of the whole Venezuela for oil exploration purposes. However they had to make a choice of the best part of that territory within a certain time limit, and my duties in Venezuela consisted, with a number of other geologists, in making surface

geological surveys, which would determine the segregation from the concessions held by the company, of the properties which were of greatest value for oil and gas exploration.

"I stayed in Venezeula about one year and then went back to work again for the Tonopah Mining Company of Nevada. This time the Tonopah Mining Company employed me as an examining mining engineer in exploration work for the company. This mine examination work embraced examinations of mining properties in practically all of the mining states of the Unted States and also in Nicaragua. After my work in Nicaragua I returned to Tonopah and performed the duties of acting chief engineer for the company for a year at Tonopah.

"In 1917 I took a position with the Empire Gas and Fuel Company as petroleum geologist. In this position my work was confined to detailed structural surface geology in the Osage field, Oklahoma. I left this position in 1917 to do geological exploration with a company which eventually was known as the Hamilton Oil Corporation. This company did geological exploration work in several states, and while in its employ I had to make examinations of properties for them in the states of Oklahoma, Texas, Kansas and Kentucky. My work then embraced surface and sub-surface geology, estimates of oil and gas reserves and detailed surface geological structural surveys of properties.

"In 1921 the Hamilton Oil Corporation sold out their properties to what is now the Continental Oil Company and for a year I worked as a consulting geologist in association with Mr. C. L. Severy, in Tulsa, Oklahoma.

"In 1923 I again went to work for the Empire Gas and Fuel Company, this time as a petroleum geologist in the Rocky Mountain Division, with offices at Denver, Colorado. During my work for the Rocky Mountain Division of the Empire Gas and Fuel Company, I had to make surface geological examinations and determinations of the value of properties in the states of Colorado, Utah, New Mexico, Wyoming and California.

"At the end of 1926 I left the Rocky Mountain Division of the Empire and took a position at the offices of the Em-

pire Gas and Fuel Company, Bartlesville, Oklahoma, as geologist in charge of exploration work for the Cities Service Gas Company. My work with this company embraced subsurface geological work, geological work involved in estimating gas reserves, and was largely connected with the analysis and recommendation to the company of gas pipe line projects.

"In other words, when gas was developed in various localities, it was part of my work to report to the company whether or not it would be profitable to build gas pipe lines to those places. This of course involved estimates, estimating what reserves might be available and whether or not these pipe line projects would be economical.

"In the course of my work in this connection, the Cities Service Gas Company built its gas pipe line from the Panhandle field to Wichita, Kansas, and from there to Kansas City, Missouri. This pipe line now furnishes Kansas City with some of its gas. This pipe line was constructed in 1928 and extends from the Cities Service Gas Company compressor station in the outskirts of Pampa in the northwest quarter of Gray County in a northeasterly direction through Roberts and Hemphill Counties, Texas, to Wichita, Kansas. From Wichita, Kansas it goes to Kansas City, Missouri. After a study of conditions in the Panhandle field, I made the geological recommendations for the construction of this pipe line.

"Also in my work for the Cities Service Gas Company, through a study of the geological conditions in certain abandoned gas fields owned by the Cities Service Gas Company, I recommended the storage of gas in these abandoned gas fields. These gas storage projects are now working on a commercial basis. During the summer when the main trunk gas pipe line does not have a peak load, gas is now stored in these abandoned gas fields, near cities being furnished with gas. During the winter when the pipe line has a peak load, this stored gas is available for any emergency.

"In 1930 I left the employ of the Cities Service Gas Company and took a position as Chief Geologist for the Continental Construction Corporation. The Continental Construction Corporation was the predecessor of the Texoma

Natural Gas Company and the Natural Gas Pipeline Company of America. My duties as Chief Geologist for the Continental Construction Corporation were confined to the study of geological and gas production conditions in the Texas Panhandle gas field.

"In July 1931, the Texoma Natural Gas Company opened offices in Amarillo, Texas. I was then and have been since then Chief Geologist for the Texoma Natural Gas Company and in that capacity have been studying geological and production conditions in the Texas Panhandle field continuously up to the present time.

"As Chief Geologist for the Texoma Natural Gas Company I have an organization under my direction which is known as the geological department. In this department is my assistant, Mr. W. F. Brainerd, a graduate geologist. He is a graduate of the Department of Geology of Syracuse University and took his Master of Science degree at that university in 1922. He has been employed in economic geological work for over seventeen years. We work together a great deal of the time on details of the geologic work, the geologic work involved in drilling wells and the gathering of production statistics. He is very experienced in microscopic work in the examination of samples and cuttings of the formations encountered during the drilling of wells, and he has done a great deal of that microscopic work under my direction.

"For this microscopic work we have some of the best microscopic equipment obtainable. This consists of a Spencer microscope with special lenses and special lighting equipment to light the stage. This microscope was made especially for the examination of well cuttings from sedimentary formations. Sedimentary formations are those formations which in the majority of cases contain oil and gas accumulations.

"Also in my department is a draftsman, who keeps our lease, production, rock pressure and geological maps up to date and keeps the map files and does miscellaneous drafting work.

"My stenographer and secretary handles correspondence

and keeps files on geologic data, statistics of production, scouting data and logs of wells.

"In addition we have a man who does some of the work of plotting up graphic well logs and collects, washes, dries and files samples of well cuttings from the wells drilled in the field.

"The cuttings of each well are filed separately so that at the different depths in each well sampled, we can examine the cuttings of the formations encountered and know what they are.

"We examine not only samples of cuttings from the wells drilled by our company but also samples from wells scattered over the field. In this way we determine the places where the formations occur, the structural conditions in the field and the position in the formations where the gas and oil occur.

"We have examined with the microscope well cuttings from over 600 wells in the Panhandle field. In the course of doing this we have examined over 12,830 samples and have on file in our office for reference over 60,000 samples of well cutting from the Panhandle field.

"In the preliminary work in the field we used to take well cuttings from the surface all the way down to the total depths of the wells, because it was necessary to find out exactly what the conditions were in all formations, and we did not wish to overlook any possibilities in the upper formations.

"As a result of our experience in examining the wells located in different portions of the field, we are now able to narrow our examinations to certain portions of the formations in certain parts of the field.

"My duties for Texoma involve choosing the best locations for the drilling of wells; the determination of the points at which casing must be set in wells; the determination of what depth wells shall be drilled; the determination of the relative value, geologically, of acreage owned by Texoma; the determination of what leases shall be drilled or acquired; and the keeping of permanent records of wells

drilled. These are called well logs. A well log is a record kept by the driller of a well. This record shows the formations encountered in the well, the depths at which they are found, the occurrences of oil, gas, or water which are encountered in drilling the well and the depths at which they occur.

"I have personally spent a great deal of time in studying conditions during the drilling of Texoma's wells, especially in getting the thickness of the gas producing formations, and also in getting information of this nature regarding wells all over the field.

"It is a very important matter to Texoma Natural Gas Company to know what amount of gas is being and has been produced from the Texas Panhandle field. For this reason it has been one of my duties to keep abreast of the production of gas in that field and I have done so throughout the period that I have been serving in the Panhandle field as Chief Geologist for Texoma Natural Gas Company.

"Determination of Thickness of Gas Pays in the Texas Panhandle Field

"1. General Discussion.

"By the thickness of pay is meant the total thickness of gas producing portions of the formations which produce gas. Gas in the Panhandle field occures in intermittent porous streaks, with barren rock between them, in the Dolomite, Dolomitic Limestone, and Limestone zones of the Big Lime, and in the Granite Wash when it is productive. These porous pay streaks vary in thickness and the thickness of pays is determined by totaling the thickness of the pay streaks.

"For anybody to correctly interpret and determine the thickness of pays as shown in the records of logs, it is necessary to have had experience in watching the drilling of gas pay section in the field. It is also necessary to know from experience what the procedure of the drillers is when they record the occurrence of the gas in making up their records of the wells. For instance, in the drilling of some of the earliest wells drilled in the field, gauges of the wells

would be taken at certain intervals during the drilling of a well and these gauges would show increases of gas for those intervals; however, the intervals for which the increases of gas were shown did not consist entirely of gas pays. The gauges were not taken at sufficiently frequent intervals to delineate the gas pay streaks or the barren streaks of formation lying between the gas pay streaks.

"Often matters like this can be cleared up by consultation with the drillers of the wells, by reference to the record of the well showing the formations encountered and, especially by reference to the drilling tickets of a well which show the amount of time involved in the drilling of formations.

"For instance, when a well is being drilled through gas pay formations, the formations are drilled at a much faster rate than when the formations do not have gas pay in them. All these matters have been considered by the writer in determining the thickness of gas pays in the Panhandle field.

"Many of the records used are far from being perfect and have been difficult to interpret. To aid in interpreting these records, I have carefully watched the actual drilling of the gas pays in a great many wells and have talked with a great many drillers in the field to find out their method of recording the occurrence of gas on the wells they drilled.

"To obtain information on this matter, I have personally spent a great deal of time studying conditions during the drilling of Texoma's wells. Many times I have gone out to a well and stayed on the derrick floor for periods ranging from 18 hours to 36 hours. In some cases I have been on a derrick floor 72 hours without any sleep so as to get actual information regarding the formations encountered, the way they were encountered in the well, the way that gas was encountered in the well, the actual thickness of the formation containing the gas and how it acted when it was encountered. I have personally, during the drilling of wells, gauged them during their drilling at five-foot intervals to find out just where the gas was and have had assistants of mine working on shifts gauge wells at five-foot intervals during the entire process of drilling in the gas pays.

"In determining the thickness of gas pay during the drilling in at five-foot intervals, the method is to take a gauge of the well when gas is encountered and determine the open flow at that point. Then, after the well has been drilled five feet, it is again gauged to determine the open flow and then, after another five feet has been drilled another gauge is taken and the open flow determined.

"This process is carried on until all the gas producing formations have been drilled. This shows whether or not there is an increase of gas at five-foot intervals during the drilling of the pay. If the open flow taken at the beginning of a five-foot interval is less than the open flow obtained at the end of a five-foot interval, the record shows an increase of gas during the drilling of that five-foot interval and it is considered that that five-foot interval is in gas producing formation. If the open flow taken at the end of a five-foot interval is less than the open flow taken at the beginning of a five-foot interval, then the record shows that there was a decrease of open flow during the drilling of that five-foot interval and it is considered that that five-foot interval did not contain gas producing formation.

"After these records have been compiled, the intervals which show an increase of gas and are considered to contain gas producing formation are added together, giving the total pay thickness of the gas producing formations encountered in the well. Wherever records in this detail were available, this method was used in obtaining the thickness of the gas pays encountered in wells. I have in my office the well records of over 6,000 wells. In determining the gas pay thicknesses in the field, these well records were combed and as many as possible used in different areas of the field to obtain the average thickness of pay in the field. A great many records were so indefinite as regards records of pay thickness that they could not be used. A great many of the records used were far from perfect, but from knowledge of the method used by the drillers in logging well pays and from records which showed the amount of time involved when drilling the formations these records could be interpreted.

"II. Details of Determination of Thickness

"1. Acreage Classification.

"For convenience in estimating the thickness of pay, the writer has divided the acreage of the field into two classifications; viz:

"a. Best Commercial Gas Acreage

"b. Marginal Gas Acreage

"Following this page is a map of the Panhandle field showing the boundaries of the field and sweet and sour gas areas used in the determinations of thickness."

Mr. Keffer: Mr. Peterson, if I may suggest to the Examiner and to the others, it might be well to glance at the map which is on the following page while Mr. Peterson reads the explanation of the map. I think it will mean more if that is done.

The Witness: "The sulphur gas line is slightly different from the present line, but is merely used as being convenient for the segregation of areas. On this map, the best commercial gas area is colored yellow and the marginal gas area is colored gray. The uncolored areas in central Gray County is designated as unproductive acreage by the Railroad Commission of Texas. The uncolored area in southwestern Moore County is believed by the writer to be unproductive on account of a dry hole drilled there.

"The best commercial gas acreage is that in which the average initial virgin open flow is above 5,000 Mcf. per well and comprises the areas which have received the most intensive development and about which the most data can be obtained. In drawing the boundary line of the yellow area, I picked out the best commercial part of the field as closely as possible, but there are some places in this area where there are wells with an initial open flow below 5,000 Mcf. per well. These areas, however, were comparatively small and the small wells were surrounded with wells of larger open flow so that the area as a whole had to be considered as the best commercial gas acreage.

"The marginal gas acreage is on the marginal edges of

the field except in central Gray County, where it comprises a large part of the field. The average initial open flow of this area is less than 5,000 Mcf per well, but the data obtainable about the area is limited on account of the small amount of development done to date in a large part of it. This area contains some wells with an open flow above 5,000 Mcf. per well, but there are very few of these wells and, for this reason, the acreage as a whole cannot be considered in a class with the best commercial gas acreage. This area seems to be an area with small average open flow. The area includes a number of dry holes and uncommercial gas wells.

"2. Determination of Thickness of Pay in Best Commercial Gas Acreage.

"In the case of the best commercial gas acreage, enough data was available so that averages of pay thickness could be determined satisfactorily.

"On the map showing the best commercial gas acreage and the marginal gas acreage will be noted a north-south line extending through the central portion of Gray County which divides the Panhandle field in what is known as the 'West Field' and what is known as the 'East Field.' This is a line which was adopted by the Railroad Commission of Texas for proration purposes. In determining the thickness of pay for the best commercial gas acreage (colored yellow on the map) this area was divided up into 13 smaller areas, the acreage in each of which was carefully determined. These areas were the sweet and sour gas areas of each county in the West Field and in the East Field. The designation of these areas with their corresponding acre content are shown on Table 1 which follows this page.

"For each of the areas mentioned above, the thickness of pay in wells scattered over these areas so that they would be representative were determined and then the average thickness of pay per well in each area was determined. The results of this work are shown in Table 2 which follows Table 1.

"It will be noted that in obtaining these averages, the records of 627 wells were used. The average thickness for each of the designated areas shown in Table 2 having been

determined, this average thickness was multiplied by the number of acres in each respective area, the result being the number of acre feet in each respective area. Then the number of acre feet of the areas involved in the best commercial area were added, the result being the total acre feet in the best commercial gas area. Then the total acre feet in the best commercial gas area was divided by the amount of the total acres in that area, the result being the weighted average thickness per acre in that area. The details of this computation are shown on Table 3 and it will be noted that the weighted average thickness per acre obtained by this method was 70.01 feet. It is considered, then, that 70 feet is a representative figure for the thickness of gas pays in the best commercial gas area of the Panhandle field. This area contains 1,033,970 acres."

Mr. Keffer: Mr. Peterson, as to Table No. 1 and Table No. 2 and Table No. 3, I suggest that you not read those but that the reporter be instructed to copy them in as a part of the testimony.

The Trial Examiner: Very well, Mr. Keffer, the Examiner will instruct the reporter to follow that suggestion.

(At the direction of the Trial Examiner, the following Tables were copied into the record.)

"Table 1

Best Commercial Gas Acreage in Texas Panhandle Oil and Gas Field

County	Sweet Gas	Sour Gas	Total
	West Field Gas Acres		
Carson	195,300	13,560	208,860
West Gray	65,445	2,970	68,415
Hartley	800	13,677	14,477
Hutchinson	40,002	99,834	139,836
Moore	260,377	122,538	382,915
Oldham	—	—	—
Potter	107,347	—	107,347
Total West Field	669,271	252,579	921,850
	East Field Gas Acres		
East Gray	17,620		17,620
Wheeler	94,500		94,500
Total East Field	112,120		112,120

Best Commercial Gas Acreage—Summary

Total Gas Acres—West Field	921,850
Total Gas Acres—East Field	112,120
Total Gas Acres—Entire Field	1,033,970
Total Sweet Gas Acres	781,391
Total Sour Gas Acres	252,579
Total Field Gas Acres	1,033,970

Table 2

Calculation of Average Thickness of Gas Producing Formation Per Well in Designated Areas of Best Commercial Gas Acreage

County	No. Wells Used*	Total Thickness Producing Formation (Feet)	Average Thickness Producing Formation Per Well
West Field			
Sweet Gas Area:			
Carson	103	8839	85.82
West Gray	77	3800	49.35
Hartley	0		33.50**
Hutchinson	24	1481	61.67
Moore (Except SW Corner)	87	6804	78.21

Potter	16	1475	92.19
Sour Gas Area:			
Carson	36	2037	56.58
West Gray	18	934	51.89
Hartley	2	67	33.50
Hutchinson	87	5481	63.00
Moore (Except SW Corner)	51	3110	60.98
Moore (SW Corner)	0		33.50**
East Field			
East Gray	31	1616	52.13
Wheeler	95	4208	44.29

*Well records were combed for thickness of producing formations. All records with this information were used that would give a representative average. Many records gave no information as to thickness of producing formation and could not, therefore, be used. 627 wells were used in this calculation.

**For the southwest corner of Moore County in the sweet and sour gas areas and the sweet gas area of Hartley County, the same thickness is used as that obtained for the sour gas area of Hartley County, which is contiguous to the southwest corner of Moore County.

Table 3.

Calculation of Weighted Average Thickness of Gas Producing Formation in Best Commercial Gas Area.

County	No. Wells Used	Average Thickness Producing Formation Per Well (Feet)	Gas Acres	Acres x Feet (Acre-Feet)
West Field.				
Sweet Gas Area:				
Carson	103	85.82	195,300	16,760,646.00

Wheeler	95	44.29	94,500	4,185,405.00
Total West and East Fields:			1,033,970	72,389,081.98

Total Field—Weighted Average Thickness Per Acre — $\frac{72,389,081.98}{1,033,970} = 70.01$ Feet

70 Feet Used

Peterson further testified as follows:

On cross-examination the witness testified that he used the driller's logs to a certain extent in determining pay thickness. Some of them were sufficiently detailed that he could get all of the information he needed about pay thickness from them, but others were in such condition that he found it advisable to investigate also the drill tickets turned in by the drillers from which the logs were made. (Vol. LXIX, p. 10090.) During the last 10 years the logs have been better than in prior years. (Vol. LXIX, p. 10092.) Some logs are better today than others but all give valuable information. (Vol. LXIX, p. 10093.) Some logs were discarded because of inadequate information. (Vol. LXIX, p. 10094.) Not all of the discarded logs, however, were inaccurate. Some were discarded because the witness tried to get a representative picture of the condition in an area and for that reason he selected wells that would be fairly and evenly spaced over an area. (Vol. LXIX, p. 10095.)

The purpose of dividing the field into areas was in order to get a more of less uniform spacing of the wells in each area to get a truer average. (Vol. LXXII, p. 10449.) He could use closer spacing in one area than in another but by weighting out the thickness as shown in Exhibit 206, a more accurate average was obtained. (LXXII, p. 10450.) He utilized the most reliable data obtainable. (Vol. LXXII, p. 10459.) In selecting the wells used he spaced them in the different areas in order to get a representative picture regardless of productivity. The wells were spaced so as to give a good average. (Vol. LXXII, p. 10469.) It was necessary to divide the fields into sectors so a better average could be obtained—one that was more representative. If he had taken 16 wells in Potter County for example, and then 16 wells in Moore County, it would have been necessary to take the same number of wells in each county over the field regardless of his information and it wouldn't have given an accurate picture. A determination was made for each area. He utilized more wells in one area than in

another if he could get the proper spacing that would justify him in doing so. (Vol. LXXII, p. 10472.)

He does not recall the exact date on which all of the data was assembled, but he has been assembling it over a period of some 10 years and spent a great deal of time assembling data and information in computing the real thickness, all of which is recorded in Exhibit 206. (Vol. LXXII, pp. 10482, 10483.)

The determinations of pay thickness were made some years ago and were not made for the purpose of utilizing them in any litigation. They were made in order to get definite information that was reliable for operating purposes. (Vol. LXXIII, p. 10554.)

Mistakes or differences in the determination of pay thicknesses tend to compensate each other in the final analysis when the averages are assembled. 627 wells were used in all in the determination of the average pay thickness. If there was a total error of as much as 627 feet in all the wells used this would make a difference of only one foot in each well on the average. The thicknesses are also weighted by areas. The average thickness in each area is multiplied by the acreage in each section or area and the product is divided by the total acreage in the entire yellow area, Exhibit 206 (which is over one million acres). This has the effect again of dividing any error that there may be, so that the whole process develops into one which consists of dividing the error if there is an error. Vol. LXXXII, pp. 12240 and 12241.)

The witness also was cross-examined with respect to the determination of his best commercial area (yellow) and marginal area (gray) as shown on the map contained in Exhibit 206, and on redirect examination figures were quoted as to the natural average open flow at 430 pounds virgin pressure for the entire marginal (gray) area as follows:

Carson County, sweet gas area, the average was 2,900,000 cubic feet per well.

Gray County, West Field, sweet gas area, the average was 3,018,000 cubic feet per well, eleven of which wells were dry holes.

Moore County, sweet gas area, had no wells but the nearest well to it was a dry hole.

Potter County, sweet gas area, the average was 4,100,000 cubic feet per well.

Carson County, sour gas area, the average was 4,720,000 cubic feet per well, which included one dry hole.

Gray County, sour gas area, the average was 1,615,000 cubic feet per well.

Hartley County, sour gas area, the average was 3,500,000 cubic feet per well, but there was one well with an open flow of 10,600,000 cubic feet, which in the opinion of the witness, represented a small part of the area.

Hutchinson County, sour gas area, the average was 3,373,000 cubic feet per well, but if three additional dry holes were considered the average would be 2,650,000 cubic feet per well.

Moore County, sour gas area, the average was 3,583,000 cubic feet per well.

Collingsworth County, sweet gas area, the average was 2,038,000 cubic feet per well.

Gray County, east field, sweet gas area, the average was 3,500,000 cubic feet per well.

Wheeler County, sweet gas area, the average was 3,993,000 cubic feet per well. (Vol. LXXXII, pp. 12235-12239.)

Peterson further testified (Vol. 68, pp. 9945-9948) as follows:

The Witness: "Determination of Average Effective Porosity of Gas Producing Formation in Best Commercial Gas Acreage of Panhandle Gas Field, Texas.

"As geologist in charge of exploration work for the Cities Service Gas Company, part of my work consisted of estimating recoverable gas reserves for scattered producing properties in the Midcontinent fields in Oklahoma and Kansas. These estimates were made in order to determine whether or not it would be advisable to purchase properties, or to build gas pipe lines and purchase gas from specific

properties. Many estimates had to be made where there was no production data available for use of the pressure decline method.

"The whole object in estimating recoverable reserves, is to determine what gas can be recovered. The gas that can be recovered depends upon the action of the wells through which the gas is recovered. By this I mean the producing characteristics of the wells. Of course these producing characteristics depend upon the formations producing the gas. Where there is large permeability in formations without large decrease in rock pressure when heavy quantities of gas are withdrawn from the formations, it follows that there is a corresponding porosity in the formations to accomodate the gas. Thus in many fields there is a relationship between open flow and the gas content of the formations. Like conditions of porosity and permeability in the formations are reflected in the behavior of gas in wells, under the same physical conditions.

"When I was making the recoverable gas estimates referred to above, the back pressure method of testing wells for open flow was in the course of being developed and no information of this character regarding wells was available to me. It was always a help to me in making decisions about my recommendations and estimates, to observe in the field, tests made of wells for rock pressure and particularly for open flow and the operation of blowing a well until its open flow was stabilized. I could tell more about the dependence to be placed on recovering gas from those wells by watching them tested, than I could from reading records. For this reason I used to accompany the men who tested wells for the Cities Service Company to the field and observe the test of the wells. In this way I began to correlate my estimates with field conditions and with thickness of pay and open flows, and by figuring back from my results and production records, formed conclusions about the effective porosity of the producing formations.

"As a result, this experience has established a criteria for judgment so that after working in a field, studying the producing formations, determining their thickness, watching well behavior and ability to deliver gas under varying conditions of rock pressure and open flow, I can weight

the different field conditions and arrive at conclusions regarding average effective porosity and gas acre content, which are practical for reliable estimates of gas reserves.

"Since July 1931, I have been working in the Texas Panhandle field, watching the testing and drilling in of gas wells. I have studied the behavior of the gas wells under varied conditions of delivery of gas, at different open flows and rock pressures and have examined thousands of samples of well cuttings. I have studied porous pay cuttings from gas wells as well as from oil wells. I have had access to records of determination of porosity made from cores of the oil producing formations, which are the same formations which produce gas. I have studied the plotted back pressure curves of wells, which curves show the producing characteristics of wells.

"Correlating all this information together with my experience in other gas fields, I have reached the conclusion that the average effective porosity in the best commercial gas acreage of the Texas Panhandle field is 20 per cent. (This is the area colored yellow on the map attached to the exhibit.)

"It is significant that this same porosity of 20 per cent is noted as applicable to this area of the Texas Panhandle field in the following publications in the bulletins of the American Association of Petroleum Geologists:

"'Gas a Big Factor in the Texas Panhandle' by C. Max Bauer.

"Vol. XII, No. 2, pp. 165-176 and 'Geology and Occurrence of Natural Gas in Amarillo District, Texas' by Victor Cotner and H. E. Crum, Vol. XVII, No. 8, pp. 877-906.

The witness stated on cross-examination that porosity and pay thickness determines the volume of gas in place (Vol. LXXIII, p. 10561) and if the porosity is equal in any two cases the more pay thickness you have the more volume you have. (Vol. LXXIII, pp. 10561, 10562.) Open flow is an indication of relative porosity. (Vol. LXXIII, p. 10565.) However, permeability is a factor that determines open flow but you generally have porosity to accommodate the permeability and you can't have permeability without por-

osity. (Vol. LXXIII, p. 10562.) There is a relationship between open flow and porosity although open flow depends partly on permeability and partly on porosity, but it does not depend entirely upon permeability in any manner. (Vol. LXXIII, p. 10564.)

Commission counsel had marked as Exhibit 216 the working paper of the witness which showed certain porosity tests on cores in the Dolomite Zone of the Texas Panhandle Field made by the Phillips Petroleum Company in March, 1940. The cores were from 19 oil wells and cover 1,015 tests and gave an average porosity of 13.08%. (Vol. LXXII, p. 10370.) The range was from zero to 30%. (Vol. LXXII, p. 10372.)

Commission counsel then had marked as Exhibit 217 a working paper of witness which showed certain porosity tests by Stanolind Oil and Gas Company. The average porosity shown on these tests was 13.21%. (Vol. LXXII, p. 10379.) The Stanolind was unwilling to give the witness the details of its tests but did permit him to make an examination of the details and authorized him to utilize the average porosity as shown by such tests. (Vol. LXXII, p. 10380.)

Commission counsel then had marked for identification as Exhibit 218, core analysis tests furnished witness by Shell Petroleum Corporation, covering the Buff Dolomite in the Texas Panhandle Field. The determinations were made on samples taken at one-half foot intervals. (Vol. LXXII, pp. 10431, 10432.) These cores were taken all the way through the pay formation. (Vol. LXXII, p. 10423.) Witness has examined many more porosity determinations which he could not offer in evidence because they were confidential, but they always came out with about the same average porosity in old producing formations. (Vol. LXXII, p. 10425.)

There is a big correspondence between permeability and porosity in the Texas Panhandle Field—with a large permeability you generally have a large porosity. (Vol. LXXII, p. 10434.) It is improper in the determination of this matter to pick out a few samples only. The proper manner in which to determine the question is to take the averages of all of the samples with respect to porosity and permeability determinations (Vol. LXXII, p. 10440.)

Drill cuttings are known all through the oil and gas profession—they are used by hundreds of companies for examination purposes and many people all through the profession examine them for porosity. (Vol. LXXII, pp. 10414, 10415.) A cutting is just a piece of the formation that has been cut by the bit whether it is a rotary cutting or a cable tool cutting (Vol. LXXII, p. 10388), but a cable tool cutting or sample is better and purer than the rotary sample. (Vol. LXXII, p. 10390.) Samples of cuttings are gathered while the well is being drilled. Cuttings are frequently blown out of the well where gas has been encountered and witness follows the practice of putting in a vent line which leads out from the top of the wellhead 100 feet or more from the rig and samples are sometimes collected in this vent line as the well is drilled. Some of the samples are as much as a quarter of an inch in size. (Vol. LXXII, pp. 10410, 11.) He has picked some samples off the derrick floor that were as much as half an inch in diameter and has made a very careful examination of them. (Vol. LXXII, p. 10412.) He can tell by the appearance of the samples and by an examination of them whether they come from pay formation or not and such samples show the porosity of the formation. Witness has examined thousands of samples and bases his opinion upon such examination. (Vol. LXXII, p. 10418.) Samples of well cuttings are examined to show porosity, that is, to determine the relative porosities occurring by comparison with known porosity obtained from oil wells where porosity tests have been made. In this manner witness has been able to determine average porosities. (Vol. LXXII, p. 10420.)

Witness has obtained all of the porosity core determinations that he could and such determinations tended to absolutely corroborate his idea of the average porosity in the Texas Panhandle Field. (Vol. LXXII, pp. 10422, 10423.) He has seen samples of cuttings which have been determined to have a certain porosity and knows how those samples look under a microscope. He can then take other samples and determine whether or not they are more or less porous than the ones in which the porosity has been determined. (Vol. LXXII, p. 10424.)

Permeability as Related to Porosity

The witness testified on cross-examination that wells having a small open flow generally have low permeability and wells having high open flow generally have high permeability. Gas moves rather slowly through an area of low permeability, permeability being the ability of a formation to allow fluids to flow through it or to permeate it. (Vol. LXX, pp. 10243-10245.) Porosity and pay thickness determine the volume of gas in place. (Vol. LXXIII, p. 10561.) High open flows or large wells are an indication of high reserves. Therefore, when you have large permeability and you produce large volumes of gas out of the well, you must have large volumes in the formation in order to produce it. Consequently, you have also a high porosity. There is not a great deal of porosity in the small wells. The open flow of such wells goes down easily and it takes a long time for them to build up, which indicates a tight formation and a small reserve. You can always tell from the open flow of a well whether it is supported by a large reserve or a small one. The witness would certainly consider that a lease which has a 50,000,000 cubic foot well on it is a great deal more promising, and one that has a higher reserve, than a lease with only a 5,000,000 cubic foot open flow well. It is possible in some fields to have a high porosity and a low permeability but experience shows that this is not true in Texas Panhandle Field. Experience in the Texas Panhandle Field shows small open flow wells consistently produce less than large open flow wells. (Vol. LXXI, pp. 10312-10317.)

Porosity and permeability in the Texas Panhandle Field are very closely related. (Vol. LXXII, p. 10434, Vol. LXXIII, p. 10563.)

Dry Holes and Abandoned Wells

Exhibit 210 was prepared by the witness for the purpose of showing the dry holes and abandoned gas wells in the Texas Panhandle Field. Exhibit 210-A contains a list of the dry holes in the Texas Panhandle Field as shown on the map, Exhibit 210. Exhibit 210-A shows the name of the company drilling the well; the well number; the landowner upon whose land the well is drilled; the location of the well; the total depth of the well, and the date the well was com-

pleted, and the quadrant in which each well was located, as shown upon Commission Exhibit 179 by Hammer.

The abandoned wells on Exhibit 210 are marked in a deep red while the dry holes are marked with a black and red circle with the center colored yellow. The outlines of the field as shown on Exhibit 210 are the same as shown on Commission Exhibit 179 by Hammer. The quadrants as outlined on Exhibit 210, were copied from Hammer's Exhibit 179. (Vol. LXIX, pp. 10339, 10340.)

Witness testified on cross-examination that the map, Exhibit 210, shows approximately 104 dry holes, which is a small number for the size of the Texas Panhandle Field, but which are very significant. The purpose of the map is to show that certain areas of the field are absolutely unpredictable from any information obtainable and that those areas are certainly undesirable for drilling purposes or for development. (Vol. LXIX, pp. 10102, 10103.) Dry holes are sometimes drilled right in the middle of what was thought to be a good producing part of the field. This is significant. Texoma drilled a dry hole right in the middle of a highly productive area and you might go in the middle of the Canadian acreage and do the same thing. In the southwest corner of Moore County there is shown on Exhibit 206 a barren spot or dry island colored in white, which indicates that that area is very doubtful territory, but before a dry hole was drilled it looked very good. You can get dry holes in the most productive areas. (Vol. LXIX, pp. 10108, 10109.)

Texoma drilled a dry hole in Section 18, Block 26, E. L. & R. R. Railroad Company survey, Moore County. This dry hole is surrounded by gas wells within a mile and a half of it in most directions. This well was drilled in the center of a number of productive wells. (Vol. LXIX, p. 10110.) The two dry holes above referred to were drilled in an area that would have been considered as structurally high in the midst of productive gas wells. (Vol. LXIX, p. 10118.) It is possible that other dry holes will be drilled under similar circumstances. (Vol. LXIX, p. 10117.)

The abandoned wells shown on Exhibit 210 were taken from the books of the Railroad Commission. Their records

showed these wells formerly produced gas and were then abandoned. (Vol. LXIX, p. 10083.)

Peterson testified on cross-examination that most of the abandoned wells were in low pressure areas and this fact had a lot to do with their abandonment. Most of them were in areas where the pressures had declined to around 200 pounds, or slightly below 200 pounds, rock pressure. A lot of the trouble in those wells was due to water conditions, which in some cases corroded the casing and probably allowed water to enter the gas producing formation. This water condition has caused the salting up of numerous wells and has made it necessary to abandon them. These wells are listed in Exhibit 214. This same situation prevents the pressure from building up. (Vol. LXX, pp. 10188-10193.)

The abandoned wells owned by Texoma Natural Gas Company are shown in Vol. LXX, p. 10207. The pressures at the time of abandonment ranged from 100 pounds to 145 pounds.

At the time the Texoma acquired the wells above referred to, careful tests were made to determine the condition of the well and the condition of the hole. They were all in good operating condition, which means there was no water in the wells, there was no casing trouble, and they were producing dry gas. They were not producing any oil and were not producing any water. The wells were in good dry condition and there wasn't any water coming into the hole from the bottom. (Vol. LXX, pp. 10211, 10212.)

Peterson further testified (Vol. 68, pp. 9948-9959) as follows:

"Gas Produced From Texas Panhandle Field During Its Life From the Beginning to January 1, 1940.

"It is a very important matter for the Texoma Natural Gas Company to know what gas has been and is being produced from the Texas Panhandle Field. For that reason, as Chief Geologist for the company, it has been one of my duties to keep abreast of the production of gas in that field and to ascertain from reliable sources what production has occurred prior to inauguration of activities of the Texoma

Natural Gas Company in the field, in addition to ascertaining the amount of gas currently produced each year.

"In Table 1, shown on the next page, is an estimate of total gas produced from the Texas Panhandle field on a 16.4 pound base for the life of the field to January 1, 1940. Following Table 1, is a graphic representation of the total gas produced for the period mentioned above, showing the production by daily averages for each of the years from the beginning of the field through the year 1939. This graph shows by scale the daily averages by years in millions of cubic feet and the different classifications of the usage of gas are shown by different colors. The following is an account of the method used in obtaining the figures:

A. Basis of Figures

"1. Gas produced prior to 1932

"In Table 1, the gas produced prior to 1932 is the estimate of Victor Cotner, given in the publication 'Geology and Occurrence of Natural Gas in Amarillo District, Texas' by Victor Cotner and H. E. Crum, bulletin of the American Association of Petroleum Geologists, Volume 17, Number 8, August, 1933, Pages 877-906.

"This estimate is believed to be the most reliable obtainable for this period. Mr. Cotner and Mr. Crum had conducted extensive research into the production of gas in the field in its early years. At the time prior to 1932 when they were present in the field, the Railroad Commission did not issue reports on the usage of gas by the gasoline plants. They did issue some reports on the usage of gas by the pipe line companies.

"Mr. Cotner was with the Columbian Carbon Company which company was interested in gasoline production from gasoline plants and through this connection he was in a position to obtain information on the gas which was being used by these plants.

"Mr. Cotner and Mr. Crum in making up their reports on production from the field worked in collaboration with other geologists in the field. This paper, written by Mr. Cotner and Mr. Crum, is accepted by the fraternity of geologists and members of the American Association of Petroleum Geologists as an authoritative document. I

have used the estimates of gas in that paper in testimony before the Federal courts in legal contentions between the Texoma Natural Gas Company and the Railroad Commission of Texas, and the Railroad Commission of Texas has never questioned in any way that record.

"2. Gas Produced Since 1931—Data From Railroad Commission Reports

"The estimates of gas produced since 1931 were made by the writer. The data on gas used by gas pipe lines and on gas used by gasoline plants was obtained from monthly records and reports obtainable at the office of the Railroad Commission of Texas. To prevent duplication and to give a true picture of gas used by gas pipe lines and gasoline plants, these figures have been adjusted by * * *

Mr. Keffer: You can leave out Table No. 1, Mr. Peterson. You need not read that group of figures but I take it the reporter will, nevertheless, copy that into the record as a part of your testimony.

The Trial Examiner: We will have the reporter do that.

(At the direction of the Trial Examiner, the following Table 1 was copied into the record.)

Table I.

Gas Produced From Texas Panhandle Field.

Total	715,260,000		509,362,020	7,728,518,237	

(Note on bottom of Table I.)

Carbon black is made by burning residue gas from gasoline plants. Thus gas used for carbon black is included in the column showing gas used by gasoline plants.

Gas produced 1926-1931 estimated by Victor Cotner—Geology and Occurrence of Natural Gas in Amarillo District, Texas. Bulletin A.A.P.G. Vol. 17, No. 8, August, 1933. P.P. 877-906.

Gas produced 1932-1939—Gas used by pipelines and gasoline plants from records of Railroad Commission of Texas. Balance of data estimated from weekly oil field scout reports, and Railroad Commission Records.

The Witness: I will just repeat the last sentence.

"To prevent duplication and to give a true picture of gas used by gas pipe lines and gasoline plants, these figures have been adjusted by the writer so that they differ a little from the Railroad Commission figures. For instance, in the Railroad Commission reports on gas used by gasoline plants, some residue gas is noted as being used for repressuring. This gas which is considered to go back into the gas field reservoir is subtracted out by the writer from the total gas used. Also, the gasoline plant reports include residue gas used by the Northern Natural Gas Company for gas pipe line consumption. This gas is subtracted by the writer from the totals of gas used by gasoline plants and added to the totals of gas used by gas pipe lines. Carbon black is made by burning residue gas from gasoline plants. Since the residue gas is a part of the gas consumed by gasoline plants, gas used for carbon black is included in the total of gas consumed by gasoline plants. The figures given in this estimate are on a 16.4 pound base. In comparing them with the sources from which they came, it must be remembered that the Railroad Commission figures issued from the beginning of the field through July 1935 were on a 16.4 pound base. Since July 1935, the figures issued by the Railroad Commission are on a 14.65 pound base.

"3. Gas Produced Since 1931—Estimates Not Given In Railroad Commission Reports

"The Texas Railroad Commission keeps no records on casinghead gas not treated (blown in air from oil wells). None of this gas is metered. This item represents gas blown to air from oil wells not connected to gasoline plants. The writer's estimates of this gas are based upon information from scouts in the field, the number of wells unconnected to gasoline plants and information of local conditions.

"Gas blown in air and used drilling wells is not shown in reports of the Railroad Commission. This includes gas used for fuel by oil companies. Some of this gas is metered and so far as records of this metered gas are obtainable they have been used. This fuel does not include gas used for fuel by gas pipe lines which is included under gas used by gas pipe lines. Fuel has been estimated by figuring up the wells completed each year and the well days and fuel

involved for the wells whose fuel has not been included under gas pipe line consumption. Gas blown in air is the gas blown to air during the drilling and testing of gas and oil wells completed each year. This is estimated from the gas encountered in the wells completed each year, taking into consideration the time of drilling through the gas pays and the method of completion.

"4. Gas Withdrawals From the Field During 1939

"In estimating the total gas withdrawals for 1939, the methods just described were employed, except that more metered gas records were available from the Railroad Commission; also, a few more items of gas blown to air had to be taken into account. In 1939, the Texas Railroad Commission for the first time took back pressure tests on all the gas wells in the sour gas area; operators took more back pressure tests; considerable acidization of wells occurred; and it became necessary to do more blowing of wells during operations in order to keep wells in condition for efficient production of gas. These factors were all considered. The total gas produced from the Texas Panhandle gas field during 1939 was estimated as follows on a 16.4 pound pressure base:"

Mr. Keffer: You may admit the table on Page 10, Mr. Peterson, and the reporter will copy it into the record.

The Trial Examiner: We will have the reporter copy in the table entitled "Gas Produced During 1939," on Page 10.

(At the direction of the Trial Examiner, the following table was copied into the record:)

Gas Produced During 1939.

	Total M. C. F.	Daily Avg. M. C. F.
Gas used by gas pipelines	222,299,905	609,041
Gas used by gasoline plants	329,653,273	903,160
Casinghead gas not treated, blown in air	7,300,000	20,000
Gas blown in air and used drilling wells	13,026,239	35,688
Total gas produced	572,279,417	1,567,889

The Witness: "B. Residue Gas Used for Carbon Black

"Carbon black is made by burning residue gas from gasoline plants. Thus, gas used for carbon black is included in the column showing gas used by gasoline plants (see Table 1). On the graph showing total gas produced from the Texas Panhandle oil and gas field by daily averages, the gas used by gasoline plants is colored brown and in this brown colored area the residue gas used for carbon black is hatched in squares. Following is a record by years of the residue gas used for carbon black during the life of the Panhandle field through 1939."

Mr. Keffer: We will have the reporter copy that table entitled "Residue Gas Used for Carbon Black—All Figures on 16.4 Pound Base," into the record.

(At the direction of the Trial Examiner, the following table was copied into the record:)

Residue Gas Used for Carbon Black—All Figures On 16.4 Pound Base.

Year	Total Gas Used M. C. F.	Average Per Day M. C. F.
1926	1,890,000	5,178
1927	11,280,000	30,904
1928	43,020,000	117,541
1929	136,374,000	373,627
1930	168,104,000	460,559
1931	120,387,000	329,827
1932	117,013,546	319,709
1933	140,866,141	385,935
1934	165,627,522	453,774
1935	175,788,287	481,612
1936	199,590,334	545,329
1937	257,633,750	705,846
1938	239,829,793	657,068
1939	260,257,224	713,033
Total Gas Used	2,037,661,597	

The Witness: "Considering the above tabulation of gas used for carbon black, it is noteworthy that the use of gas for this purpose has gradually increased each year during the life of the field except during the years 1931, 1932 and

1938. The usage of gas for carbon black fell off slightly in 1938 when a total amount of 239,829,793 Mcf. was used. However, the usage again increased in 1939 when 260,257,224 Mcf. was used. This is the largest usage of gas for that purpose for any one year during the life of the field. It is probable that this usage will continue to increase in the future.

"C. Total Withdrawals to January 1, 1939 and January 1, 1940.

"Referring to Table I, the total gas produced from the Texas Panhandle field on a 16.4 pound pressure base to January 1, 1939 was 7,156,238,820 Mcf. and the total gas produced to January 1, 1940 was 7,728,518,237 Mcf.

"D. Progress of Gas Consumption in the Texas Panhandle Field

"Referring to Table I and the colored graph illustrating it, it will be noted that except for the years 1930 and 1938 there has been a gradual increase each year in the usage of gas by gas pipe lines. In 1939, they used more gas than in any previous year, viz: 222,299,905 Mcf., which was at a rate of 609,041 Mcf. per day. Since all the gas pipe lines are not yet operating at their full capacity, it is believed that this usage will continue to increase for some time, year by year.

"The amount of gas used by gasoline plants each year has fluctuated considerably. The amount used by these plants increased steadily each year from 1926 through 1930. In 1931 and 1932 this usage of gas fell off somewhat, partly due to enforced regulations against wastage of gas by the Railroad Commission and partly on account of a business depression in the nation. Gas used for this purpose increased considerably above former usage in 1934 and 1935. This was due to the fact that the State of Texas loosened up in their regulation on the usage of gas for gasoline plant consumption during 1933 and 1934 and 1935 gasoline plants were allowed to use dry gas for gasoline and pop residue gas to the air without restriction. In 1936 the State of Texas tightened up its regulations again on the use of residue gas and would not allow the use of dry gas for the production of gasoline where the residue was allowed

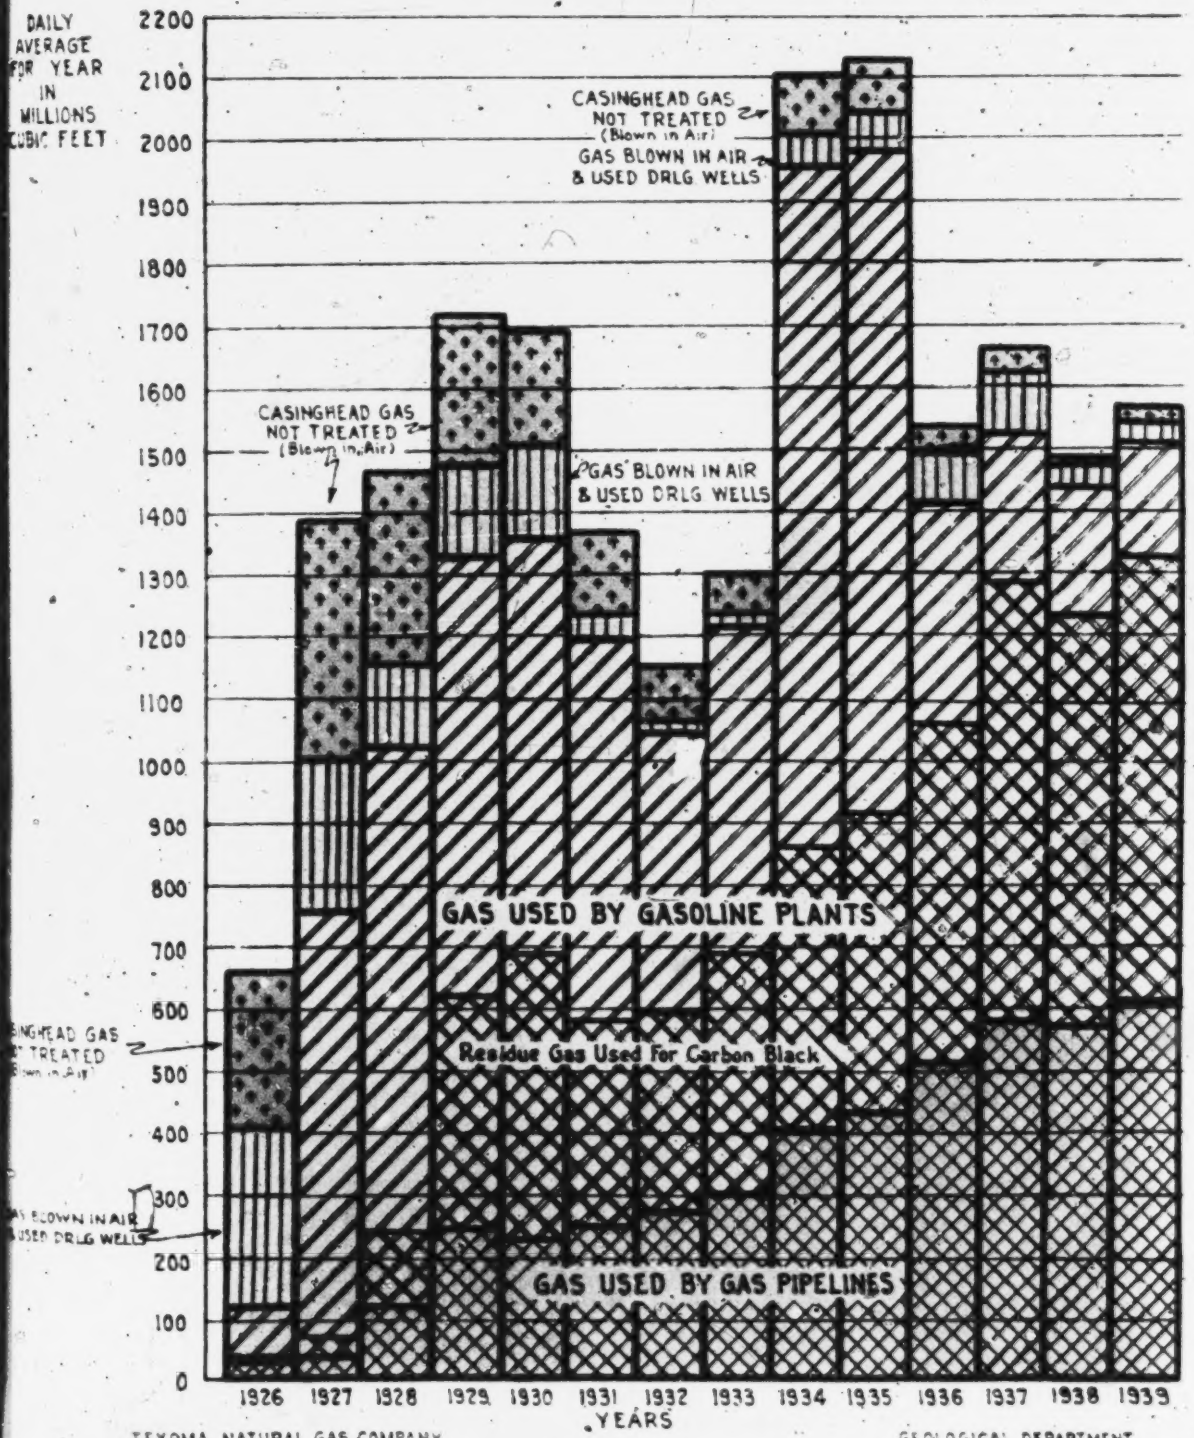
to be popped into the air. Gas used for gasoline plants increased from 1936 to 1937 and a decrease occurred in 1938, but again in 1939 there was an increase of this usage of gas over the usage in 1938.

"It seems reasonable to expect that usage of gas in the Panhandle field as a whole will continue to increase each year for some years to come."

Mr. Keffer: If I might just for one moment, I would like to have Mr. Peterson turn back to the graph between Pages 8 and 9, giving us a brief explanation of it.

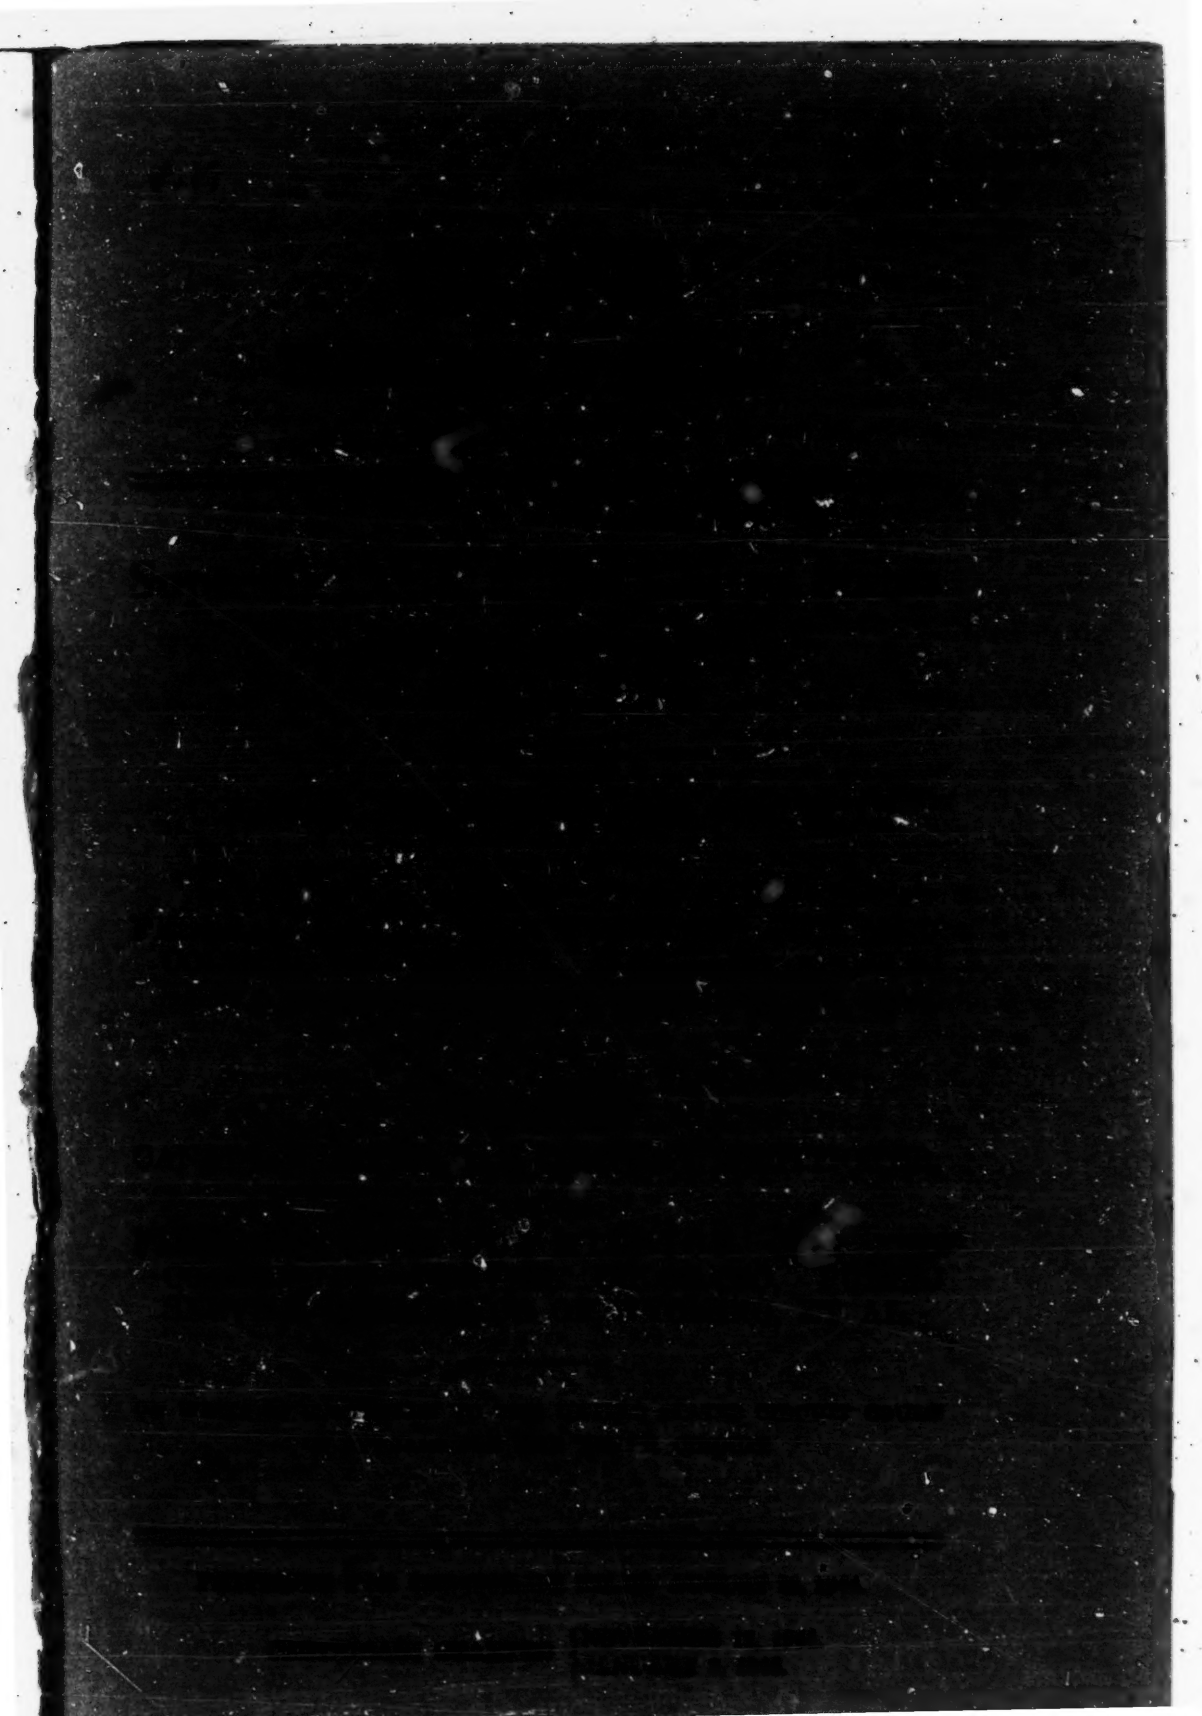
TOTAL GAS PRODUCED
FROM
TEXAS PANHANDLE OIL AND GAS FIELD
SHOWN BY DAILY AVERAGES
16.4 Lb. Base

Exhibit No. 206



TEXOMA NATURAL GAS COMPANY
Statistics by C. J. Peterson

GEOLOGICAL DEPARTMENT



United States Circuit Court of Appeals

TENTH CIRCUIT.

No. 2550.

COLORADO INTERSTATE GAS COMPANY, a corporation, PETITIONER,

vs.

FEDERAL POWER COMMISSION; CITY AND COUNTY OF DENVER, COLORADO; PUBLIC SERVICE COMMISSION OF WYOMING; COLORADO-WYOMING GAS COMPANY; and CANADIAN RIVER GAS COMPANY, RESPONDENTS.

No. 2551.

CANADIAN RIVER GAS COMPANY, a corporation, PETITIONER,

vs.

FEDERAL POWER COMMISSION; CITY AND COUNTY OF DENVER, COLORADO; PUBLIC SERVICE COMMISSION OF WYOMING; COLORADO-WYOMING GAS COMPANY; PUBLIC SERVICE COMPANY OF COLORADO; and COLORADO INTERSTATE GAS COMPANY, RESPONDENTS.

ON PETITION TO REVIEW AND SET ASIDE ORDERS OF THE FEDERAL POWER COMMISSION.

FILED SEPTEMBER 9, 1942.

VOLUME 8—Pages 4351-5063

Peterson then explained the graph (Vol. 68, pp. 9960-9963) as follows:

Peterson referred to the column which represents the year 1939, which column does not quite reach the 1600 line shown on the left of the graph. He stated that this column represented 1,600,000,000 cubic feet per day. The column representing the year 1926 shows a total production of something less than 700 million cubic feet per day.

The blue cross-hatched columns at the bottom of the graph represent the gas that goes into the gas pipe lines and during the year 1926 there was probably not more than 25 million cubic feet per day that was marketed through gas pipe lines out of a total of production of 700 million cubic feet per day produced that year.

As you go through the graph, reading to the right, it becomes more or less self-explanatory. The blue at the bottom of the graph represents the daily average of gas used by pipe lines. The next section going upwards represents gas used in carbon black plants, said columns being cross-hatched. The next section going upwards, which is represented by diagonal parallel lines, represents gas that was processed by gasoline plants, the residue of which was not used in carbon black plants. The remaining portions of the graph represent casinghead gas that was not treated in gasoline plants but was blown into the air, and also represents gas that was blown into the air and/or used during the drilling of wells.

Peterson's withdrawal figures check with the Railroad Commission's estimate. The Railroad Commission has estimated that in excess of 6 trillion cubic feet of gas have been produced in the field up to July 1936. This figure when converted from a 14.65 pound to a 16.4 pound pressure base checks with Peterson's withdrawal figures for the same period. (Vol. XC, pp. 13834-13837.)

Note: It will be observed that these volumes are all given on a 16.4 pound pressure base. The Commission representatives in quoting various figures on gas volumes have uniformly used a pressure base of 14.65 pounds. If desired the 16.4 pound pressure base may be converted to a 14.65 pound pressure base by multiplying the 16.4 pound volumes by 1.11945. (Vol. LXIX, p. 10062.)

Peterson testified on cross examination that the figures used by him in showing gas withdrawals have been checked from every possible angle and confirmed by interviewing operators in the field. (Vol. LXXIII, p. 10634.) He also checked his estimates, where reports of metered gas were not available, with various employees of the Railroad Commission from time to time, which persons are familiar with the field through daily contact with it and have confirmed the reasonableness of his estimates (Vol. LXXIII, pp. 10632, 10625, 10627); that such figures have been used in litigation with the Railroad Commission and never questioned by it. (Vol. LXXIII, p. 10597.)

The witness also checked Cotner's figures for withdrawals prior to 1932 and found them to be approximately correct. (Vol. LXXI, pp. 10335, 10336.) Cotner's estimate of withdrawals are regarded by everyone in Texas Panhandle Field to be as good as can be made. (Vol. LXXI, pp. 10340-10345.)

Cotner had access to the records of gasoline plants which were not available to the public, which plants at that time were highly competitive and kept abreast of not only what they produced themselves, but what their competitors were utilizing. Cotner also collaborated with practically all of the geologists that were then working in the Texas Panhandle Field. (Vol. LXXI, pp. 10341, 10342, 10346, 10347.)

In estimating gas blown into the air during the drilling of wells, the witness stated that he had reports on the wells drilled, both gas wells and oil wells, and the open flows of gas wells, and with this information and with information as to the total hours utilized in drilling through pay formations he made estimates as to the amount of gas that was blown into the air and used while the wells were being drilled through the gas producing formations. He has kept a very careful record of this on wells drilled by Texoma Natural Gas Company, this being a part of his duties as Chief Geologist of that company. He kept a chronological record showing the gauges of the volumes of gas encountered at fifteen-foot intervals and the number of hours engaged in drilling and by adding up these amounts after a well was completed he could determine the total volume of

gas that was wasted into the air, as compared to the open flow volume of the various wells drilled and by this means he worked out a factor based upon the open flow volumes encountered. The methods of drilling utilized by Texoma are the same methods utilized by other operators in the field and it takes about the same time to complete a well through the producing formations. His factor is somewhat different for each county in the field, based upon the time required to drill through producing formations in various portions of the field. The average volume of gas lost for each well drilled during each year has remained about the same for each year. Pay formations can be drilled in a shorter length of time in some counties than in others and this accounts for his different factor for each county. (Vol. LXXIII, pp. 10636, 10641-10646. Vol. LXXIV, pp. 10753, 10754.)

The witness has also worked out a formula for estimating gas lost in drilling oil wells. This was determined by studying the drilling records of a great many oil wells and the volumes of gas ordinarily encountered in oil wells at different depths and by determining the number of days the gas encountered would blow into the air before an oil well was finally completed, and this averaged about 5,000,000 cubic feet for each oil well drilled as the volume that would be wasted into the air during the drilling of each well. (Vol. LXXIV, pp. 10957-10059.)

Peterson also prepared and introduced Exhibit 206-A, which Exhibit was admitted in evidence, and which is supplemental to Exhibit 206. Exhibit 206-A merely shows the gas withdrawal figures in the Texas Panhandle Field for the year 1940, and the cumulative withdrawal figures to January 1, 1941, which Exhibit is shown in Vol. 69, pp. 10037-10039, inclusive, and which is as follows:

EXHIBIT NO. 206-A.

Gas Withdrawals From Texas Panhandle Field.
During 1940.

In estimating the total gas withdrawals for 1940 the methods described as used in estimating total gas withdrawals for the year 1939 were employed. The total gas pro-

duced from the Texas Panhandle Gas Field during 1940 was estimated as follows, on a 16.4 pound pressure base:

	Total MCF	Daily Average MCF
Gas used by gas pipe lines	235,860,805	644,428
Gas used by gasoline plants	337,256,848	921,467
Casinghead gas not treated blown in air	7,320,000	20,000
Gas blown in air and used drilling wells, etc.	17,029,476	46,529
Total gas produced	597,467,129	1,632,424

Residue Gas Used For Carbon Black.

Carbon black is made by burning residue gas from gasoline plants. Thus, gas used for carbon black is included in the above totals showing gas used by gasoline plants. Following is the amount of gas used for carbon black during 1940, on a 16.4 pound pressure base:

Total gas used MCF	Daily Average MCF
262,487,147	717,178

It will be noted that during 1940, as compared to 1939, there was an increase in the total gas produced of 25,187,712 MCF. Increases were as follows:

	MCF
Gas used by gas pipe lines	13,560,900
Gas used by gasoline plants	7,603,575
Casinghead gas not treated	20,000
Gas blown in air and used drilling wells, etc.	4,003,237
	25,187,712

Total Withdrawals to January 1, 1941—16.4 pounds pressure base

Referring to Table I, the total withdrawals to January 1, 1940, were 7,728,518,237 MCF
Adding withdrawals during 1940 597,467,129 "
Total withdrawals to January 1, 1941, are 8,325,985,366 "

Peterson further testified on cross examination (Vols. 72 and 73, pp. 10422-10570) as follows:

Q. Why didn't you look at a core from an oil well if you wanted to get the relative condition?

A. I have obtained all of the porosity core determinations that I could obtain of different wells—different oil wells, and I didn't have any correspondence to look at, to tell the truth. I have seen a number of cores of oil wells.

Q. These reports on cores that you got from other companies, they weren't of any particular use to you, were they?

A. They were of great use to me.

Q. In what respect?

A. Well, they tend to absolutely corroborate my idea of what the average porosity is in the Panhandle field.

Q. You don't even know what formation those cores were taken from.

Mr. Spencer: He has testified as to the formation.

Mr. March: As to whether it is the best pay or the poorest pay of the oil well, or what-not.

The Witness: Are you making a statement?

Mr. March: I am asking you if that isn't correct.

The Witness: Can you read that statement he made? I wasn't paying much attention to his statement and I don't remember it.

(The question referred to was read by the reporter as set forth above.)

The Witness: I don't think the companies were lying when they gave me the description of those cores and they stated in each case that those cores were taken from the dolomite formation, and as I said, we don't dispute the fact that you may not be able to obtain a core in the richest part of the formation, although I have gotten some cores here from the Shell Petroleum Corporation which were taken all the way through the pay.

By Mr. March:

Q. Let's look at this Phillips matter marked for iden-

tification and see whether it was taken from the best wells where you could compare a record of porosity determined from samples of cuttings, do you?

A. Well, I know it is kind of a strange thing, but I have—although I am submitting certain exhibits showing porosities obtained in the dolomite oil area, there are many more determinations that I have seen that I cannot offer in evidence because they are confidential and the peculiar thing about it is that you always come out at about the same average on these core determinations that you find. That is the reason I was trying to bring out regarding these papers which I have identified as exhibits the average porosity shown.

Q. But those porosities were determined from cores. I asked if you had any porosities of oil wells which were determined from cuttings.

A. I haven't claimed that any determinations have been made from cuttings.

Q. You don't know of anyone that has made any oil porosity tests in the Panhandle field from cuttings, do you?

A. As a matter of fact, I do, but I haven't had access to them.

Q. You haven't had access to them?

A. No, sir.

Q. You don't know what they are?

A. No, sir.

Q. I want to go to the top of this well where you are getting out these cuttings from the pay formation and where the particles are blowing out. You said you put some sort of an instrument or pipe on there where you could separate the gas from the particles so the man could get in there and catch those particles?

A. No. We put in a vent line. This vent line extends for about 150 feet from the derrick floor. It runs out horizontally and then has an elbow, you call it an "L", and a riser is put in. A lot of times we have put on a connection and extension out from the point where the riser goes up into the air. This riser is vertical, that is, as with respect to this horizontal vent line.

As the gas blows the cuttings out of the hole the cuttings come through this vent line at a very fast rate and will

go into this section of pipe. It just blows them horizontally into it before the gas goes out through the vertical riser and in that way you can get cuttings.

Q. About like the diagram here?

A. Yes, sir. That would give you a good idea.

Q. The pipe goes into crooks and then goes into dead end and the residue blows into the air?

A. Yes, and the gas will hit this—

Q. It will hit the first turn in the pipe?

A. This end here (indicating).

Q. It will hit the dead end?

A. Yes, sir, it goes out there.

Q. The larger cuttings will do that but the smaller cuttings from the best pay formation will blow into the air?

A. I haven't claimed I could get the cuttings from the best pay formation.

* * * * *

Q. Mr. Peterson, have you used your cuttings in any manner in arriving at your permeability?

A. No, sir.

Q. Nor as to open flows?

A. Not the cuttings, no, sir.

Q. Nor as to gas in place?

A. I have formed a judgment on a study of the cuttings which helps me to determine what the gas in place might be; which helps me.

Q. From your cuttings?

A. Yes, sir.

Q. If you can determine permeability from your cuttings, how can you do that when you can't rely upon the accuracy of those permeabilities from cores?

A. I haven't said that and I don't claim that I have ever determined the permeability of my cuttings.

Q. Have you determined the permeability of any wells?

A. I don't know. I wouldn't know what the permeability of a well was. Of course, it would depend upon the size of the casing and how much the diameter was. A casing with a large diameter would have a very great permeability.

Q. You have never determined the permeability of any gas wells in the Panhandle field?

A. No, sir.

* * * * *

By Mr. March:

Q. Is this all of your working papers on pay thickness?

A. This gives the result of all of my working papers on pay thickness. I would have to use the logs of the well and a lot of information that I gathered at different times and these pay thicknesses have been determined by work that was started way back in 1931. They were determined not for any hearing but for the purposes of getting information for the company. I had to use different logs, of course, in the preparation of this exhibit. The names of the wells are given there. I want to say the wells listed there are from logs in my collection at Amarillo and they have all been copied by members of the staff of the Federal Power Commission. Undoubtedly they are in their possession.

Q. I haven't asked you for those logs as yet, but the logs and this constitute the only working papers on pay thickness?

A. Yes, sir, that together with having working papers, because I have had to find out about lots of these well pay thicknesses by consulting with drillers, tool pushers—

Q. Tool dressers?

A. No, I don't think I have consulted any tool dressers, but tool pushers are quite different from the tool dressers. A tool pusher is a person who has charge of drillers ordinarily for a contractor and sees that the work is done and keeps the men supplied with the material necessary, and generally is pretty well informed on what is going on at a well, and watches things and sees that they are done in an efficient manner.

Q. I notice you have 627 wells here. Are those the 627 wells you used to get your 70 per cent pay thickness?

Mr. Keffer: Seventy what?

Mr. March: 70-foot pay thickness.

The Witness: Yes, sir.

By Mr. March:

Q. You didn't use any but these 627 wells?

A. No, sir.

Q. Will you just describe for the record the contents, how you got this data set up by wells?

A. This is a list of wells showing—wells that were used in determining my pay thickness. The sheet as set up shows the well description—for instance, the name of the company is given and then the farm name and number of the well; then the location of the well, that is, the portion of the section that it is in, and then the section number; the block number and the survey number, which identifies the well on the map. Then the pay thickness is given, which was determined for the well.

Q. How did you determine the 627 wells you used? Do you think that is covered in your written statement sufficiently?

A. Well, this is a pretty good description given here.

Q. If you are satisfied, I will withdraw the question.

The Trial Examiner: Are you withdrawing the question?

Mr. March: That is right.

Q. I believe you stated you divided the wells into sections?

A. Into sectors.

Q. You divided the sour gas from the sweet gas?

A. Yes, sir.

Q. You mostly followed county lines, did you not?

A. Yes, sir. The divisions have been made simply to give a convenient area to use.

Q. That is the only purpose of the divisions, is that right?

A. Well, to try to get a representative area so that each well—in each case the spacing of most of these sectors is practically the same in each sector. I would say that the spacing of the wells is more or less uniform in each of the sectors, taken separately, but if the sectors were grouped, you wouldn't get a true average. I have tried to get the best average—

Q. You wouldn't get a true average?

A. I have tried to get the best average I could in each sector.

Q. What if you took the whole field and ignored sectors, would you get a representative average?

A. It would be hard to get the spacing of wells available to give an even spacing of the whole field. I have tried to space these wells evenly so the average of any sector would be representative.

Q. What would be the difference if you didn't take the sectors individually in your figures as to pay thickness?

A. It would be hard to get a good average. That is all. That is because it would be hard to get your—in some of those divisions I think I used more wells than in others and that is the reason they are divided into sectors. I could use closer spacing in one sector and set it out—if another sector had a wider spacing I would use that sector and divide it up that way. That was the reason, just to try to get a more accurate average of the areas represented.

Q. You made a calculation to ascertain what sort of an average you would get if you hadn't had the sectors?

A. There wasn't—the sectors were made—if we would have had to take an average of the field, that is, if I hadn't divided it into sectors—well, let's take up the Potter County area. There your wells are very widely spread. If you had taken an average of the field and included Potter County wells with an area like Wheeler County, where you have wells on every 160-acre tract, or wells in Moore County where you have maybe a well in every section, the average wouldn't be near as true as the one you have gotten here.

Q. In other words, you divided the field up into quadrants and you are getting at your average for each quadrant?

A. I didn't intend—

Q. What would be the difference in calling these areas quadrants and sectors?

A. A quadrant is one-fourth of something.

Q. Do you recall Mr. Hammer's exhibit where we designated the sectors as quadrants?

A. I don't know how he did it. He had sixteen quarter parts in the Panhandle field.

Q. That is the only reason you wouldn't want to call them quadrants? If I referred to them as quadrants you wouldn't like that, would you?

A. No, sir. A quadrant means a quarter part of something.

Q. Do you know the United States Geological Survey has quadrants designated as they are not quarter parts?

A. No, sir. As I remember it, the U. S. G. S. publication divided it into quadrangles.

Q. Quadrangles?

A. Yes, sir.

Q. Is that right?

A. Yes.

Mr. March: It is about noon, Mr. Examiner. I can continue on but we might recess now.

The Trial Examiner: We will recess until 2:00 o'clock this afternoon.

(Whereupon, at 12:30 o'clock p. m., a recess was taken until 2:00 o'clock, p. m., of the same day.)

Afternoon Session, 2:00 P. M.

The Trial Examiner: The hearing will be in order. Whereupon—

C. J. PETERSON the witness on the stand at the time of recess, having been previously duly sworn, resumed the stand and testified further as follows:

Cross Examination (Continued).

By Mr. March:

Q. These 627 wells, they are just how extensively scattered over the field?

A. Just about what?

Q. How extensively scattered over the field?

A. Well, let's take a look at that.

Q. Do you need your working papers on that?

Mr. Spencer: No, it is in his written statement.

The Witness: Exhibit 206.

By Mr. March:

Q. While we are looking at this thing, I want to tie in this 627 wells to this Table 2 on Page 9 of your Exhibit 206. That is the 627 wells referred to there, is it not?

A. Yes, sir.

Q. Which are contained in this working paper?

A. You asked how they are distributed over the field?

Q. Yes.

A. Well, in the Carson County sweet gas area, 103 wells.

Q. You don't need to read all of that. I notice here that you indicate the numbers of wells which are found in various counties and sections, but I wondered how they are distributed over the various counties.

A. Well, the location is given in that working paper.

Q. By looking at this working paper I can determine the location of these various wells?

A. Yes, sir. That was an exhibit made up so that those wells could be located on a map.

Q. I notice here you only have 16 wells in Potter County.

A. Yes, sir.

Q. 16 wells in Potter County.

A. Yes, sir.

Q. Is it not true that most of Canadian River's acreage is in Potter County?

A. Well, I wouldn't say most of it is. I have never analyzed it. I believe most of it is, though.

Q. How many Canadian River wells do you have here?

A. Well, I would have to look at the list there to tell.

Q. Just an approximate figure is all I am interested in.

A. Canadian River and the Amarillo Oil Company which—and the Red River Oil Company which are—

Mr. Spencer: Owned by the same parent company.

The Witness: Have the same parent company—there are 16 wells. That would be the total of Canadian River wells.

By Mr. March:

Q. You don't have anything but Canadian River wells in Potter County, do you?

A. No, sir.

Q. What is the average thickness of Canadian River acreage in Potter County of those wells, approximately?

A. The average thickness is at 92.19 feet.

Q. How many for—the only other Canadian River wells I believe are in Moore County, are they not?—and Hutchinson County, or do you have any in those two counties?

A. Hutchinson and Moore—you mean in Hutchinson

County—at least four Canadian River wells in Hutchinson County.

Q. At what average pay thickness?

Mr. Spencer: Do you mean for the county or for the four Canadian River wells?

Mr. March: For the four Canadian River wells.

Q. You might read off which four they are there.

A. The four wells that I have used in Hutchinson County, sweet gas area, are the Amarillo-Bivins No. B2, 1320 feet from the east line, 820 feet from the south line, Section 90, Block 46, H & T C, 65 feet.

The Canadian River Dunaway, B1, 362 feet from the north, 1645 feet from the east, Section 5, *Blocy* Y-2, 100 feet.

The Canadian River Dunaway 2A, 2300 feet from the east line, 2310 feet from the south line, Section 5, Block Y-2, 58 feet.

The Canadian River Bivins B1, Section 11, southwest corner of the northeast quarter of Section 11, Block Y-2, 138 feet.

This makes a total thickness in all of 361 feet and an average thickness of 90 feet.

Q. Now, that is only a small area there. Let's see which wells you have left out of there. There are four wells in there which Canadian River has, aren't there? Which Canadian River wells did you leave out from your pay thickness calculations?

A. Well,—

Q. You can look right here on this map, Exhibit 95, and tell.

A. Yes. There are four wells there.

Q. Yes.

A. I will try to locate these wells.

Mr. Spencer: Won't the map itself, Mr. March, show sufficiently what wells he did not use?

Mr March: Well, if I get this working paper in evidence I think it will.

Mr. Keffer: He has already put the wells in evidence.

Mr. March: The wells aren't in evidence.

Mr. Keffer: Well, the map is in and the list is on the map.

Mr. March: The working paper is not in evidence yet. I want to check on this little corner. I want to know what wells he left out.

Mr. Keffer: And the map shows it. That's what I am stating.

Mr. Spencer: We are willing to stipulate that he did not use them all.

Mr. March: Oh, I know that. I know he didn't use them all. That is a very small corner there and I am just going to ask him about that.

Q. Can you read the open flow of those wells?

A. Here is a well in Section 11, Block Y-2, shown here, 76 million cubic feet, I believe—76 million cubic feet.

The next one is in Section 90, Block 46, 40 million cubic feet.

The next two are in Section 5, Block Y-2; one of them has 34.8 million cubic feet and the other one has 30.8 million cubic feet.

Q. Now, will you take those wells that you did not use and read off the open flow of those wells—Canadian River acreage?

A. Canadian River acreage?

Q. Yes.

A. Those aren't made up with reference to Canadian River acreage.

Q. I understand that, but it is included.

A. There is a well here in Section 4, Block Y-2, that has 8 million cubic feet.

There is a well in Section 88, Block Y-2,—Block 46, rather—that has 70 million cubic feet, and a well in Section 13, Block Y-2, that has 58 million cubic feet, just north of the one that we used that had 76 million cubic feet.

There is a well in Section 9, Block Y-2, that has 45 million cubic feet.

Mr. Spencer: Are those initial volumes you are reading, Mr. Peterson?

The Witness: These are initial open flows, yes, sir.

There is a well in Section 13, Block Y-2, that had 75 million cubic feet.

There is a well in Section 10, Block Y-2, that has 7 million cubic feet.

By Mr March:

Q. Is that all that you did not use that are in the Canadian River acreage in Hutchinson County?

A. I believe so.

Q. Do you know what the pay thickness of those wells is that you didn't use?

A. No, sir, I couldn't determine it.

Q. You could not determine it?

A. No, sir.

Q. You didn't have records you could determine it from?

A. Those wells were drilled a long while ago and it was very hard to determine the exact pay in them.

Q. Were all those you did use drilled subsequent to the wells you did not use—these you read off last?

A. I wouldn't swear on that, but it must be understood in trying to make an estimate of this kind one has to use the most reliable data he can get hold of. Otherwise, the work wouldn't be very reliable.

Q. Have you got logs on those wells you didn't use in Canadian River acreage in Hutchinson County?

A. Yes, sir.

Q. Could you have taken those logs and determined it on the wells that you did not use?

A. I believe you would find out that they are pretty hard to use, if you tried to compare them.

Q. Well, the only reason you didn't use these other wells is because you didn't have accurate data in regard to them?

Mr. Spencer: He hasn't said that was the only reason.

By Mr. March:

Q. Is that the only reason?

A. That is one of the reasons. It is not the only reason.

Q. You wouldn't want to state for the record here that

you didn't have as good data on them as you had on the others?

Mr. Spencer: He has already stated that.

The Witness: I have already stated that. That is one of the reasons. There are two reasons why I picked my wells. One is to get accurate data and the other one is to try to get more or less even spacing in the wells that I can get hold of.

By Mr. March:

Q. You find out for me which of those wells you used were drilled subsequent to those you did not use.

Mr. Spencer: Now, Mr. Examiner, unless the Examiner thinks that is important, we are not going to encumber Mr. Peterson with a lot of miscellaneous, various and sundry requests by Mr. March to furnish information on things which we think are not material.

Mr. March: If you don't want to give us those, I can get those from Mr. Thompson's working papers, I think.

Mr. Spencer: You can get it from your own working papers.

Mr. March: I don't think so.

The Witness: Don't you have the wells?

Mr. March: We may have in Washington. I have wired for 627 logs and I expect to look at every one of them.

Q. Now, let's move along over here to Moore County. How many Canadian River wells do you have in Moore County, approximately?

The Trial Examiner: Mr. March, do you mean how many wells did he use in Moore County?

Mr. March: Yes, how many wells did he use in Moore County?

Mr. Lange: In this Table No. 2.

Mr. March: Yes.

The Witness: Do you want to include the Red River?

Mr. March: Is the Red River a subsidiary of the Canadian River or wholly-owned—that's right, it is an affiliate—

Mr. Spencer: He understands—

Mr. March: He just asked me the question.

Mr. Spencer, I would like to ask you for the record: Those Red River wells, are they tied into local Texas service and not into the Denver service?

Mr. Spencer: That's right, using the term "local" relatively. They aren't tied into the Canadian River system.

The Witness: 16 wells altogether.

The Trial Examiner: Are those the Canadian River wells?

By Mr. March:

Q. Are they Canadian River wells?

The Trial Examiner: That was the question.

By Mr. March:

Q. In Moore County.

A. They are all Canadian River except one or two Red River wells.

Q. Let me see one or two of those Red River wells there. Let's see what the thickness is.

A. Red River, Shelton 1-A—is that supposed to be Red River?

Mr. Spencer: That's right.

The Witness: That's one Red River well. Canadian River Thompson well—Canadian River Reed 2-A.

The Trial Examiner: Did you get that, Mr. Reporter?

By Mr. March:

Q. Now, do you know how many Canadian River has up there in Moore County altogether—what percentage of the wells in Moore County that Canadian River has that you took?

A. No, sir, I don't.

Q. Do you know whether or not those wells that you

took have the highest pay thickness according to your own calculation?

A. The ones I took are the only ones that I have been able to determine the pay thickness on, so I couldn't very well answer the question.

Q. How many wells has Canadian River got altogether and Red River combined, since you have got both of them combined here in this discussion?

A. I don't know.

Q. You don't have any idea?

A. I have never counted them.

Mr. Spencer: Well, why mix Red River into it?

Mr. March: Well, we have got—

Mr. Spencer: There is just one in there.

Mr. March: Well, there are several more over in Potter County. Leave Red River in there. I will ask you this question:

Q. How many producing wells does Canadian River have?

A. I don't know.

Q. You never made an examination of those wells to ascertain how many they have got?

A. I never counted them, no.

Q. You didn't look over every well Canadian River has in order to arrive at which ones you would use?

A. Oh, yes, but I didn't count them at the time.

Q. As I say, you have only got 32 Canadian River wells and Red River wells in there in Potter and Hutchinson County—36—16 in Potter County, 4 in Hutchinson, and 16 in Moore?

Mr. Spencer: If you are going to make anything out of it, let's let the witness go back and count and see what he has got.

The Witness: I tried to pick out the wells that I could use and I didn't pay any attention to what company they belonged to.

The Trial Examiner: I believe that is his testimony, Mr. Spencer.

Mr. Spencer: In one instance, Mr. Examiner, he combined Red River with Canadian River wells. They weren't separated.

The Trial Examiner: That's right, in Moore County.

Mr. Spencer: I am willing to stipulate any figures you want.

Mr. March: Does 92 wells sound right for Canadian River?

Mr. Spencer: More than that.

Mr. March: About how many?

Mr. Keffer: I think today it is a hundred, isn't it—98—it's a hundred wells for Canadian River and I think now there are just—wait just a second. I can tell you how many Red River has. (Examining Exhibit 95). I think there are 13 wells of Red River and 1 now drilling that started since we came up here, since the first of the year, and I don't know whether it has been completed yet or not. It might be 14.

Mr. March: That would make 112 altogether?

Mr. Spencer: That would be a close approximation, yes.

By Mr. March:

Q. With 112 wells you could only get 36 wells on which you could make any determinations at all as to pay thickness, is that right?

A. No, I wouldn't say that.

Q. What would you say?

A. Well, when I made up this exhibit I took what was available that I could determine the pay thickness on. I think they have drilled several since I worked on this exhibit that I could obtain the thickness of, but in this area, Moore County, except the southwest corner. I have used 87 wells in all which are pretty well scattered over that whole area—pretty well spaced, and in Potter County I used all of the Canadian River wells there, which are pretty well spaced, too, for that part of the field, and in Hutchinson County itself, in the sweet field—the west sweet field, which is in that corner, I used 24 wells altogether. Of those

wells, 4 of Canadian River wells. That is a pretty good representation when you consider the acreage. It makes a pretty good spacing.

* * * * *

Q. Thickness is a pure laboratory calculation, is that right?

A. I wouldn't say so.

Q. It is more of a judgment figure?

A. No, it takes in a lot of careful work to get your thickness figured up—investigations.

Q. How would that have affected your estimate of pay thickness if you just used 16 wells in West Gray County? Do you think that would have raised your figures any as to pay thickness?

A. The reason that I have divided these sectors up is that in that way you can get a better average of each area that will be representative than if you took, say, Potter County 16 wells and then went up to Moore County and took 16 wells, or 32 wells. You would have to do that all over the field if you tried to take the field as a whole. You would have to take just about the same number of wells all over the field regardless of your information and it wouldn't give you as good a picture as I have gotten. The whole object—if you will notice, each of these sectors is a separate sector, and the sectors are not balanced with each other. They aren't related to each other at all for getting your results. No sector has been added in with another or balanced with it, or whatever you want to call it. I just made the best determination I could in each area. The reason I got more wells in one area than in another, if I could get the spacing that would justify taking that number of wells, why, I took them.

Q. I note here, and it is very interesting to me, that there are 65,445 acres in the west Gray County wet—sweet gas area, and in Potter County there is 107,347 acres.

A. Yes, sir.

Q. In the sweet gas area—and in Potter County you take 16 wells in spite of the greatly exceeding acreage, and in west Gray you take 77 wells. How do you account for any such action as that?

Mr. Spencer: Mr. March, if you had been listening instead of being so interested, he just explained it was a matter of spacing. He took the greatest number of wells

he could find where he could get them properly spaced. He has just gone through it right ahead of your question.

By Mr. March:

Q. Is that your answer?

A. Why, certainly. That is the reason I made these different sectors because I couldn't get—I'd like to have gotten a hundred wells in every one of those places if I could, because it was an important—there were only 16 wells in Potter County. I couldn't build a lot more wells.

Q. Did you say there were only 16 wells in Potter County?

A. Only 16 that I have been able to use.

Q. There are considerably more than that in Potter County, though, aren't there?

A. Yes, there are more than that.

* * * * *

By Mr. March:

Q. Now we come to the actual determination of pay thickness or the actual procedure by which that pay thickness is determined. As I read your statement and as I have listened to your testimony here, although you have logs on these 627 wells, that you do not rely upon those logs solely for your determination of pay thickness.

A. No, sir.

Q. Why don't you rely on those logs for the determination of pay thickness?

A. Because some of them were rather inadequate and I was able to check, though, and get some information at different times that gave me a clue to use them.

Q. Where are the notes and the data which supplement those logs?

A. I haven't any data to supplement them because I made—as I say, if I had been preparing this for an exhibit, I would have a lot of data, but I wasn't preparing it for an exhibit. At least I didn't have any idea of ever offering it as an exhibit when I worked it up.

* * * * *

Q. Has your estimate of reserves over the years changed much?

A. No, sir. As I got more information, I have tried to improve it. I want to draw the—I would like to draw your

attention, Mr. Examiner, to something about this estimate—just an explanation.

The Trial Examiner: Well, it is a matter of explanation of an answer to a question that Mr. March has asked—

Mr. March: I have no objection, Mr. Examiner.

Mr. Spencer: Is what you are going to say in explanation of some answer you have made to a question propounded by Mr. March?

The Witness: I wanted to draw attention to the method used in obtaining the thicknesses—that is, the method by which the area is divided all the way through—this whole area.

Now, for instance, referring to the Table 2 in Exhibit 206, you will note I summed up the total thickness, for instance, in Carson County—103 wells—summed up the total thickness and then divided by the number of wells used and that gave me an average per well of 85.82. Now, since I used 103 wells there, in order for there to be a difference, we'll say, of one foot in my average, I would—that would accommodate an error of 103 feet—if I had a total error of 103 feet, why, that would only make a difference of one foot in my average, and if you consider the whole 627 wells that have been used, to accommodate an error of one foot in my average, would necessitate an error in the whole computation of only—of over 627 feet so that if I did make errors, why, the whole process lends itself to dividing the area. This is further carried on when the averages—when it is averaged—the average obtained and weighted per acre.

In Table 3, the average obtained for each area is multiplied by the acreage obtained in the acre feet, and then the whole is divided by the total number of acres in the error which is 1,339,700, which serves further to serve as the method—it lends itself to dividing the area, whatever it might be in greater thickness or less thickness. You would have to have an awful big error there to shorten the average in the end.

* * * * *

By Mr. March:

Q. Who were some of those drillers you were talking to?

A. I am not going to attempt to tell you because it is impossible for a man to remember people ten years back.

Q. Can you tell us one driller you have talked to who has agreed to tell you about the pay thickness?

A. I am not going to tell you about any of it.

Q. You wouldn't tell me any of their names?

A. I have consulted some of them but I'm not going to try to get into that.

Q. I will ask you to cite a single driller who will agree with you as to pay thickness.

The Trial Examiner: What's that?

By Mr. March:

Q. I will ask you to cite a single driller who will agree with you as to pay thickness of a given well.

A. I didn't say that they agreed with me as to pay thickness. I said by investigating and talking to them I determined what the pay thickness was.

Q. If they didn't agree with you, how could you determine it?

A. I could find out what they were drilling through—when they were drilling through the pay thickness and what the pay thickness was. They didn't try to determine pay thickness. They would tell me how they were drilling at different places and where they got the pay, but they didn't add it up or try to determine it.

Q. These logs don't even show pay thickness, do they?

A. A lot of them do. I just said that I used a lot of logs just as they were. I already have made that statement.

Q. If you don't want to tell me the name of a single driller, that is all right. We will now go to this 12½ per cent of the drillers you talked to. I want to know the 12½ per cent of the other type of men you talked to. They were the pushers, you say, and the people keeping records on the well?

A. Yes, sir. I am not going to attempt to estimate any percentages because it is impossible for a man to do it.

Q. I don't want you to. I have all the percentages I need. Now I need a little fill-in here. Can you name a single pusher that agreed with you on pay thickness?

Mr. Spencer: Has he testified the pushers determined sand thickness yet?

The Witness: No, sir. As I say, I have obtained different information from these people that enabled me to determine pay thickness. They never determined pay thickness for me.

By Mr. March:

Q. Who are some of the individuals?

A. I am not going to try to name them. I have seen so many of them, I do not want to try to name them.

Q. Who is one of the pushers?

A. I don't think I am going into that.

Q. That is all right with me. So we get to the 25 per cent now. Did you talk to somebody who had connections with the drilling of the well? Now we come to the other 25 per cent which had no connection with the drilling of the well, but which were officials of the company—

A. They were company representatives—

Q. What were they—geologists and the like?

A. Yes, sir, company geologists and company scouts.

Q. You talked to the Phillips Petroleum Company's geologists on some of their wells as to what pay thickness they had?

A. Yes, I have talked to a number of them at different times.

Q. Did they agree that you could determine pay thickness of any of their wells?

Mr. Spencer: He hasn't testified they determined any sand thickness.

The Witness: I got information from them which I could use.

By Mr. March:

Q. None of the Phillips representatives told you that you contacted in the field, this 25 per cent of the representatives of the companies you contacted in the field, told you and agreed with you as to the pay thickness?

A. Yes, I have asked them at different times as to what the pay thickness would be—what they thought the pay thickness would be, and they told me what I said.

Q. Phillips?

A. Yes.

Q. Did they say they could determine pay thickness accurately?

A. They told me what they considered the pay was.

Q. Who was that?

A. Different ones there—

Q. Who, for example?

A. That is kind of hard to go into, trying to tie a Phillips man down to something.

Q. You are relying upon it, aren't you?

A. Certainly, at the time I relied upon it.

Q. Well, the Examiner has to rely on this and we want to have it backed up, if possible, or not backed up—I doubt whether it can be backed up or not. Whom did you talk to?

A. Well, I talked to Tom Craig of the Phillips Petroleum Company about different wells.

Q. Tom Craig gave you the pay thickness?

A. Yes, sir, he told me what he thought was the pay thickness and where he thought the record was inadequate, and other things. You see, we bought quite a number of wells from the Phillips Petroleum Company.

Q. What is Tom Craig?

A. Tom Craig is a geologist for the Phillips Petroleum Company in Amarillo.

Q. Is he in charge of the Amarillo office? Mr. Knight is district geologist, isn't he?

Mr. Spencer: Just a minute. Let the witness answer the other question.

The Witness: Tom Craig was district geologist ahead of Mr. Knight. Now Mr. Knight is district geologist and I don't know Tom Craig's official capacity. It was when he was district geologist I used to consult with him about these wells.

By Mr. March:

Q. About when was that?

A. Back in 1931 and 1932.

Q. You haven't consulted with anybody from the Phillips Petroleum Company since then?

A. Yes, at different periods.

Q. And with Mr. Knight, present district geologist?

A. Yes, sir.

Q. Did he give you the pay thicknesses?

A. No, sir.

Q. Why wouldn't he give you the pay thicknesses?

A. I don't think I consulted him about pay thicknesses.

Q. Who else did you consult?

A. Those are the only two geologists that I have known with Phillips in the field.

Q. You say Tom Craig showed you where the pay thicknesses were inadequate.

A. He didn't think that the record was good.

Q. You never asked Mr. Knight what he considered to be the pay thickness of the Phillips wells, have you?

A. Well, I have had so many conversations with these gentlemen that it is hard to remember just what definite information they gave me at different times. We are all very well acquainted with each other.

Q. So, therefore, none of the 25 per cent here were taken from the Phillips? They were not consulted as to the effective pay thickness subsequent to 1932?

A. No, sir.

Q. You just said Mr. Knight didn't give you any opinion as to pay thickness?

A. I said I couldn't remember what I talked with him about at different times, but he has helped me on pay thickness; that is, he has given me information.

Q. Are you familiar with his testimony that you can't use pay thickness in the Panhandle field of Texas to determine it?

A. I am not familiar with any of his testimony anywhere. I haven't read any of his testimony and don't know what you mean.

Q. Did he orally inform you that you could not determine the pay thickness of the Panhandle field of Texas?

A. Who?

Q. Mr. Knight.

A. No, sir.

Q. Did he say you could?

A. I have never heard him express an opinion on the subject.

Q. You have never heard him express an opinion on pay thicknesses at all, have you?

A. I have asked him about pay thickness in certain of the Phillips wells—

Q. Which wells?

A. I can't remember now, Mr. March.

Q. What did he say when you asked him about the pay thicknesses of certain Phillips wells?

A. He told me what he thought the pay thickness was in those wells.

Q. I see. I want those wells designated so I can check on that.

Mr. Spencer: He said that he can't remember.

The Witness: I can't possibly remember.

By Mr. March:

Q. Did you use a great many Phillips wells in this estimate here?

A. I used a few of them, quite a number of them, but I have never counted them to see what they were.

Q. Were they some that you used here that you talked to him about?

A. I couldn't remember concerning that, Mr. March. This work has gone on over a period of ten years and a man can't remember all of those details.

Q. Did Mr. Knight tell you the pay thickness of the oil wells, or were they gas wells?

A. I have inquired of him about pay thickness in oil wells and gas wells both.

Q. But you can't say whether or not there are any of those used here in your 627 wells that you asked him about?

A. As I say, I can't remember.

Q. I see. All right, we will move along.

What other geologists did you consult, company representatives, did you consult, relative to these pay thicknesses in the 627 wells?

A. Oh, I consulted the geologists of the Texas Company and the geologists—

Q. Just a minute. Whom did you consult with The Texas Company?

A. Mr. Schwartz, District Geologist, at Pampa.

Q. Did they have many gas wells?

A. The Texas Company?

Q. That's right.

A. I think they have quite a number of them.

Q. Were they included in the 627 wells you consulted Mr. Schwartz in regard to?

A. Yes, sir.

Q. Did Mr. Schwartz tell you the way it was done?

A. He gave me no information that helped me to determine it.

Q. Which wells were they? Were they all of The Texas wells here? Can you check through without going through the exhibit here?

A. I can't remember which one I consulted him about. I consulted him with the one idea—

Q. Which one did you consult him about?

A. I can't tell.

Q. No one else can tell by examining those logs of yours?

Mr. Spencer: What someone else can tell, you hardly and I can hardly tell until it is looked at.

Mr. March: I doubt whether you and I could even tell.

Mr. Spencer: You and I are pretty smart. We might be able to take it out of there.

The Witness: Do you expect me to answer a question about what somebody else can or cannot do?

By Mr. March:

Q. You can't tell me, then, the wells you consulted—the wells that you were having trouble with and consulted The Texas Company about?

A. No, sir.

Q. And Mr. Schwartz gave you some information about some wells that you were having difficulty with and he helped you to determine the pay thickness?

A. Yes, sir.

Q. He didn't say what the pay thickness was, did he?

A. I can't remember.

Q. All right, who else did you consult? What other geologists? What other company representatives did you consult?

A. Well, I consulted geologists with Gulf Producing Corporation.

Q. Whom did you consult there?

A. Mr. Terrell.

Q. When did you consult him?
A. At different times during the past ten years.
Q. Is he still district geologist?
A. No, sir, he isn't there at the present time.
Q. How long has he been gone?
A. I don't remember exactly.
Q. Approximately?
A. Less than a year.
Q. Less than a year?
A. Yes.
Q. Mr. Schwartz is still with The Texas Company as a geologist?
A. No, he is not with The Texas Company.
Q. How long has he been gone from there?
A. I can't remember that either.
Q. You don't even remember the last time you consulted him?
A. No, sir.
Q. You haven't consulted him in recent years?
A. No, sir.
Q. You haven't consulted him since 1932?
A. I doubt if I have consulted him since 1932.
Q. When was the last time you consulted Mr. — this Gulf man?
A. I can't remember.
Q. You can't tell.
A. I don't think anybody could remember things like that.
Q. Even approximately?
A. No, sir, not even approximately.
Q. Did you take notes when you consulted people as to the pay thickness, as to the 25 per cent of these walls, these geologists?
A. I took notes when I tried to determine the pay thickness.
Q. Where are the notes?
A. I haven't any of them.
Q. How many did you consult down there?
A. I have consulted the geologists of the Empire, now known as the Cities Service Oil Company.
Q. The Cities Service Oil Company?
A. Yes, sir.

Q. Whom did you consult there?

A. Archie Kantz.

Q. What is he?

A. The District Geologist for the Empire, now known as the Cities Service Company.

Q. Is he still the district geologist?

A. Yes, sir.

Q. About how many of these wells did you consult him about?

A. I can't remember.

Q. You can't remember any particular well you consulted him about?

A. No, sir.

Q. Did you consult him very much?

A. I don't know what you mean by very much.

Q. Did you consult him about a great number of wells or with the few wells you were having trouble?

A. A few wells at various times I wanted information on—I consulted him about those.

Q. Does he have a tabulation of pay thickness of these wells?

A. No, sir.

Q. Do you know of anybody that does have that information but you?

A. I have no way of telling what these men possess.

Q. I thought you went in and talked to them and asked them what the pay thickness was.

A. I asked them for information to enable me to determine it. I am not claiming these men determined my pay thickness.

Q. Did they in any case tell you what the pay thickness was in a number of cases?

A. Yes, sir, in a number of cases.

Q. Did the Cities Service man tell you?

A. Yes, sir.

Q. Which wells?

A. I can't remember now.

Q. If you can't remember which wells, how can you remember whether or not he told you what the pay thickness was?

A. Because I can remember that I had to check some wells up with him and to make my determination.

Q. About when was that?

A. I can't remember which wells there were.

Q. About when was it?

A. I can't remember when it was, except that it was during the past ten years.

Q. It is all very hazy?

A. No. I have never kept a diary on these things.

Q. It is more than I can see how you can keep all of these things in your head to say that a 75-foot pay thickness—

A. At the time I worked this up I took a record of the total pay thickness at the time I determined it. It was on a list and this exhibit—

Mr. Spencer: This working paper?

The Witness: This working paper—

By Mr. March:

Q. Which list was destroyed?

A. No,—

Q. The original list you took it from—

A. I threw it away after I got it typed up.

Q. You didn't throw it away until the Federal Power Commission requested you make up a list like that?

A. I was trying to remember whether I ever had it typed up before—I think I had—after I had it typed up in good form I threw away the old list. What good was it?

Q. My question was, did you have it typed up before the Federal Power Commission made the request for you to produce those pay thicknesses on those 627 wells?

A. Yes, I had it typed up at different times.

Q. Do you have those 627 wells on the list and no more?

A. Yes, that is all I have ever been able to use.

Q. All you have ever been able to use? How many wells are there in the Panhandle field of Texas?

Mr. Spencer: Gas wells?

Mr. March: Yes.

The Witness: Just a minute. I want to qualify that answer I gave. I will say it is all I have been able to use to try to get a representative spacing of the wells.

By Mr. March.

Q. How many more have you been able to use to determine pay thickness?

A. I don't know, Mr. March.

Q. Approximately how many?

A. As a matter of fact, I haven't worked up any more than I have in that list there because that was all I needed for the purpose I was using it.

Q. You picked out those wells and determined the pay thickness on those particular wells?

A. Yes, sir.

Q. In other words, those other wells which you from time to time talked about and maybe made notes in regard to pay thickness on, you don't have any data on those wells at all?

A. The only wells I ever had any notes on are the ones in this working paper.

Q. How many gas wells are there, approximately, in the Texas Panhandle?

A. Approximately 1600.

Q. 1600?

A. Yes.

* * * * *

A. About two and a half miles from the edge of the field.

Q. You said it was how far from the D-4 well?

A. It is about 1⅝ miles.

Q. All right, did you use that well—Masterson M-1 as I read it here—H-1—it could be N-1?

A. It is the well in that Section 3, Block B-11.

Q. You know which well it is.

A. Yes. I didn't use it, no.

Q. Now, Mr. Peterson, we have made a complete circle around this largest well of the Canadian River Gas Company and we found that you only used one of those wells, the one with 18 million open flow. Now, you can look there. Do you see any wells any closer than the ones I have indicated that we have discussed?

A. The one I used is the one north of the Masterson.

Q. The 18 million open flow well?

A. The 18 million open flow, yes, sir.

Q. Now, Mr. Peterson, why didn't you use any of those

other wells? For example, why didn't you use the Masterson D-4?

A. Well, it probably was on account of the fact that I couldn't interpret the record or get enough information on it. As I say, these thicknesses were determined by using the best information I could get. If I had wells with information that I couldn't use and couldn't satisfy myself that I had a satisfactory determination, I didn't use them.

Q. Is that the reason you didn't use those other wells that I read off?

A. I believe that is the case. These determinations were made up a long while ago and not for any litigation or anything. They were made up in trying to get definite information that I thought was reliable.

Q. In your opinion, did that one pay thickness on that one well, assuming it is correct, does it indicate the pay thickness of that region?

A. Well, averaged with other wells in the big area involved in Potter County there, in wide spacing, why, it gives a pretty good average of that area.

Q. How do you know? You don't know what the pay thicknesses of those wells are.

A. No, sir.

Q. Does the pay thickness vary with your open flow?

A. Not necessarily.

Q. Well, you just don't know what the pay thicknesses of the wells are in that entire region, then, do you? It's bound to be variable, isn't it?

A. Sometimes you can't always get all the information you want in a region, but I am trying to get an average of the area as a whole.

* * * * * *

By Mr. March:

Q. You haven't made an estimate of reserves of the whole field on the open flow method of estimating reserves, have you?

A. I have never said that I had used an open flow method of estimating reserves.

Q. All right. Do you agree with this statement—reading from Page 895 of the Cotner and Crum report.

"The great variations of open flow of wells in the Texas Panhandle field indicates considerable differences both in porosity and thickness of pay strata."

The Trial Examiner: That is from Exhibit 215?

Mr. March: Yes.

The Witness: What page is that on?

Mr. March: I am reading from Page 895.

Mr. Spencer: How does that quotation begin?

By Mr. March:

Q. "The great variations of open flow of wells in the Texas Panhandle field indicates considerable differences both in porosity and thickness of pay strata."

The question I am asking you is, do you agree with that sentence here?

A. Well, if you put in the next sentence with it.

Q. I am asking you about that sentence, then I'll ask you about the next one.

Mr. Spencer: That is a complete answer. He says yes with the explanation.

Mr. March: Let him put in the explanation. I don't care.

Mr. Spencer: That's all we are talking about.

The Witness: The next sentence says, "porosity is the main factor."

By Mr. March:

Q. Then you do agree and you do contend that open flow has a direct relationship to pay thickness, is that right—contrary to your previous contention?

A. No, sir, that is not what it says here.

Q. Then you don't agree with it—I mean you don't agree with the statement I just made?

A. Let's hear the statement.

Mr. Spencer: I have difficulty whether you want him to agree with you or Crum and Cotner.

The Witness: I thought you were talking about Crum and Cotner.

Mr. Spencer: Wasn't that answered?

Mr. March: No, there wasn't, and I don't want to be deferred. I want it answered.

(The record referred to was read by the reporter as set forth above.)

The Witness: I think I answered that. I stated it two or three times that you can't determine pay thickness by open flow.

Mr. March: All right, that's all there is to it.

Now, do you know for certain where those small particles are coming from when they are blown out of the well, whether they are coming from the pay or what-not?

A. Well, the particles themselves generally speak for themselves.

Q. Do you know?

A. You can tell by an examination of the particles whether it comes from the pay or not.

Q. How can you tell that?

A. You can tell by the appearance of it and by examining it. Is shows the porosity.

Q. It shows the porosity?

A. Yes, sir.

Q. Can you determine the porosity mathematically from the samples?

A. You can get an idea from looking at them.

Q. Can you give me the porosity determination you made on any well?

A. No, sir. I was just trying to get ideas of the situation down there as a whole. I have examined hundreds of thousands—thousands of samples to base my opinion upon that.

Q. Have you a single record down there that shows the result of an examination of any well for porosity, what the porosity of that well was?

A. No, sir.

The Trial Examiner: We will stand in recess for five minutes.

(At this point a short recess was taken, after which proceedings were resumed as follows:)

The Trial Examiner: The hearing will be in order.

Mr. Spencer: May I ask the witness one or two questions, Mr. March?

Mr. March: Yes, sir.

Mr. Spencer: Will you explain to the Examiner the different uses that are made by your department of the well cutting samples which you take?

The Witness: The well cutting samples that we collect are used for a number of purposes. Before we reach the gas pay the samples are used to determine exactly what formation we are drilling in so that we can set our casing in a well at a point as close to the pay formation as possible. After we have set our casing the samples that are used mainly to determine the formations in which we are drilling so that we can determine what formation we are in; so that we can determine when we go from one producing pay formation to another; so that we will know at what depth it is advisable to stop drilling a well; so that we can determine what formations we end the well in. Those are the main uses we make of our sample cuttings.

Mr. Spencer: Just one more question.

To what extent generally have you used well cuttings in making your determinations as to porosity of the formations encountered?

The Witness: I have used all well cuttings that I could obtain that showed porosity to get an idea of the relative porosities occurring in the well and to compare these cuttings and the occurrences of the bores with the cuttings obtained from oil wells where tests had been made which gave a general idea of what the average porosity might be.

By continually watching these samples I obtained a judgment of what the variability was and from the relative values reached an idea of what the average might be. It is mainly a relative form of getting a relative idea of porosities in the formations. It also gives an idea of how porous the rock looks in some of the big wells and things like that.

When we were drilling through some of the big gas pays at times I have been chased off the derrick merely by the shower of particles falling on the floor.

By Mr. March:

Q. You mean the flowing out of the gas? You mean the particles were blown out by the gas?

A. Yes, and we picked them up.

Peterson further testified (Vol. 69, pp. 10104-10120) as follows:

Mr. March: I'll repeat it.

Q. Do you know of any other gas field to your knowledge that has as good a record as this field in regard to dry holes—gas field, I am speaking of now?

A. Well, let's see, that's 104 dry holes out of approximately 1600 gas wells. That would be about 1/16th. I am not certain, but I think the Homer field has a better record than that.

Q. Where is that?

A. Down in Louisiana.

Q. You don't know about that, though, do you?

A. That's the trouble with the question. You would have to make a study of all these fields to know exactly what the percentage of the dry holes was.

Q. About what is the percentage, do you know, down there?

The Trial Examiner: You mean this field in Louisiana that he mentions?

Mr. March: That's right.

The Witness: That's the trouble, I'm not certain. He is asking me to try to compare this field with all the fields in the United States and I will have to admit I don't know how to do it without doing a lot of reference work.

Mr. March: All right.

Q. Now, let's see, I notice a rather unusual thing about these dry holes, that there are very few of them in Canadian River acreage, is that correct? Do you understand the question, Mr. Peterson?

A. Yes, sir, that is correct.

Q. By the way, before we go any further, my question as to dry holes—did you include in your figure the abandoned gas wells, too, your 140 figure?

A. 104 was the figure I stated.

Q. Does that include—I was just asking you about your dry holes. I haven't got to abandon gas wells yet. I want to be sure I got that figure.

A. From what I can make out, there are 103 dry holes. It might be 104, though.

Q. 103 as distinguished from your abandoned wells?

A. Yes, sir.

Q. I just wanted to get that clear. As I see here you only have two dry holes in the Canadian River acreage, is that right?

A. I don't show any dry holes here on Canadian River acreage.

Q. You don't?

A. No.

Q. Are there any?

A. Well, I think that they have some outside the boundaries of the field.

Q. We are talking about the field now—Canadian River has not drilled a single dry hole in the field, is that right?

A. I believe that is right.

Q. In other words, every time they put a well down they have got gas, is that correct?

A. Yes, sir.

Mr. Keffer: May I ask a question there, Mr. March?

Mr. March: Sure.

Mr. Keffer: I'll tell you what it is in advance—

Mr. March: Go right ahead, Mr. Keffer.

Mr. Keffer: Have there been any dry holes drilled, Mr. Peterson, on lands adjacent to Canadian River lands?

The Witness: Yes, sir. There have been two dry holes right adjacent to those.

By Mr. March:

Q. Who drilled those?

A. Texoma Natural Gas Company.

• • • • •

Q. How many wells has Texoma Natural Gas Company, approximately?

A. About 165 wells.

Q. Only two dry holes. Do you know of any company

in the Panhandle field with the exception of the Canadian River Gas Company that has a better record as far as dry holes is concerned, than the Texoma Natural Gas Company, taking into consideration the number of wells drilled?

A. Well, I hate to say that. I really don't know.

Q. You don't know of any, do you?

A. No, sir.

Q. How many dry holes—strike that.

As I counted there are only 10 dry holes east of the County line of Hutchinson County and Carson County here—pardon me, west of the County line of Hutchinson and Carson counties, in the gas producing formation. I mean by that, as I count the dry holes here in the entire eastern portion of the field—the western portion of the field, the portion west of the east line of Hutchinson and Carson Counties in the gas producing portions of the field, I don't believe there are but 10 dry holes there, is that correct?

A. West of the east line of Carson County in the west gas field?

Q. That's right.

A. I haven't tried to pick the dry holes in the oil area.

Q. I am talking about commercial gas acreage.

A. I think that is correct.

Q. I notice you counted one up here in the oil acreage. Is that oil acreage that dotted line coming up in—

A. It is close to the line there. I thought it was right on the line there.

Mr. Lange: In Hutchinson County?

The Witness: In Hutchinson County.

By Mr. March:

Q. That is approximately correct, isn't it?

A. I think that is correct.

Q. You wouldn't have any difficulty in saying that you didn't know of a field in the history of this country that had a better history as far as dry holes, just taking the dry holes? Could you make a statement like that without any fear that you were making an incorrect statement, to your knowledge?

A. No, I don't believe I do.

Peterson further testified (Vol. 82, pp. 12214-122[illegible]) as follows:

Did you know there are some 80 wells located in the Borger-Lefors area in which pressures have been increasing—have increased since 1935?

A. I have an impression that there are some wells in that area in which the pressure is increasing but I haven't made a study of the exact number.

Q. Do you know?

A. But I haven't made a study of the exact number.

Q. Do you have any idea as to what percentage of those wells you used in calculating your pay thickness?

A. Not having made a study and not knowing what wells the pressure is being increased in, I have no way of telling how many of those I used in my pay thickness.

* * * * *

Q. And you stated in your cross examination this morning, except for very isolated instances your marginal area was controlled to a great extent by the open flows that you found in that area, did you not?

A. Yes, sir.

Q. Did you take into account structural conditions where your wells—where not many wells had been drilled?

A. Yes, sir.

Q. All right, will you state the average open flow which you found in the gray area?

A. I have this worked out for the different divisions of the gray area. For Carson County west field, sweet gas area, the average 430-pound natural open flow was 2,900,000 cubic feet. This was from seven wells which had a total 430-pound open flow of 20,300,000 cubic feet.

In the Gray County west field, the sweet gas area, the average 430-pound open flow was 3,018,000 cubic feet. This took into consideration 28 wells, 11 of which were dry holes.

The Trial Examiner: You mean by that, Mr. Peterson, you included 11 dry holes in your average?

The Witness: Yes, sir, to give an idea of what the area might have.

The Trial Examiner: As I take it now you are arriving at the average open flow of the wells in that area?

The Witness: I have to count the dry holes in as an open flow of zero, because they show a bad condition.

The Trial Examiner: I see. Very well.

The Witness: Now, in Moore County west field, sweet gas area, there was a very small area, and the only thing near this area was a dry hole.

In Potter County west field, the sweet gas area, it had one well with 430-pound open flow of 4,100,000 cubic feet.

In Carson County, west field, sour gas area, the average 430-pound flow was 4,720,000 cubic feet. This was obtained from five wells, including one dry hole.

In the Gray County west field, sour gas area, the average 430-pound open flow was 1,615,000 cubic feet.

In Hartley County, west field, sour gas area, the average open flow from two wells was 3,500,000 cubic feet, while the open flow from another well was 10,600,000 cubic feet, which is in my opinion representative of a small part of the area.

In Hutchinson County west field, sour gas area, the average 430-pound open flow was 3,373,000 cubic feet. This was taken from a total of 11 wells and included no dry holes.

Considering three additional dry holes, the average 430-pounds open flow in this area would be 2,650,000 cubic feet.

The Moore County west field sour gas area had an average 430-pound open flow of 3,583,000 cubic feet. This included 10 wells and included no dry holes.

The Collingsworth county east field, sweet gas area, had an average 430-pound open flow of 2,038,000 cubic feet. This was from two wells.

Testimony of J. D. THOMPSON, JR.
Witness for Canadian.

J. D. THOMPSON, JR., witness for Canadian, testified with respect to gas reserves in the Texas Panhandle Field (Vol. 65, pp. 9965-9973) as follows:

A. "My name is J. D. Thompson, Jr. I was born in

Johnstown, Ohio, January 31, 1891. I now live in Amarillo, Texas.

"I graduated from Denison University, Granville, Ohio in June, 1914, receiving the degree of Bachelor of Science, my major subject being geology. After receiving my degree I spent approximately two years doing graduate work at Cornell University in Ithaca, New York. My work there was largely confined to advanced courses in Geology but also included duties as instructor in laboratory work offered to the under-graduate students by the department of Geology. My work at Cornell University extended over the period from September 1914 until April 1916, at which time I took a position as field geologist for the Empire Gas and Fuel Company at Bartlesville, Oklahoma. I have practiced my professior as oil and gas geologist continuously since April 1916 to the present time.

"I was employed by the Empire Gas and Fuel Company for a period of three years during which I did field work in Ontario, Canada, New York State, Pennsylvania, Ohio, Indiana, Missouri, Illinois, Kansas, Colorado, Oklahoma, Louisiana and Texas. My work for the Empire Gas and Fuel Company was varied and may be best described under three headings.

"1. Plane-table surveys in which I did detailed mapping of structural geology as shown by rock beds outcropping on the surface of the earth.

"2. Reconnaissance work in which I scouted ahead of the plane-table crews searching for areas in which favorable conditions of structural geology were present. Upon my recommendation such areas would later be mapped in detail by the plane-table crews.

"3. Subsurface structural geology work in the oil and gas fields of Northern Louisiana. In areas such as this last one mentioned, where surface outcroppings of the rock beds offer only meager information as to the structural condition existing below the surface of the earth, the structural geology of the area is worked out by a study of the logs and sample of the drill cuttings of the wells drilled in the area. This is known as subsurface work.

"In the spring or summer of 1919, I resigned from my position with the Empire Gas and Fuel Company and took up work for Mr. Leroy Adams, an independent oil operator with headquarters at Wichita, Kansas. My work for him included both detailed surveys and reconnaissance work in Kansas, Oklahoma, Wyoming, Montana, Ohio, Kentucky, Mississippi, Alabama, Tennessee, Georgia and Florida.

"In April 1922, I moved to Amarillo, Texas, where I took a position as district geologist in the Texas Panhandle area for the Gulf Oil Corporation, which was then known as the Gulf Production Company. I was employed by them continuously for seven years until the summer of 1929. My work for this company may be divided into three phases.

"The first phase may be called exploratory work which covered a period from the year 1922 until the year 1926. At the time I took up my work in this area, only two oil wells located in northern Carson County and some 20 to 25 scattered gas wells had been completed there The production from the two oil wells was being pumped into steel storage tanks since there was no oil pipe line leading from the field at that time.

"Of the gas wells a group of perhaps ten or fifteen in Potter and Moore Counties were being operated by the Amarillo Oil Company which had built a pipe line to the city of Amarillo where it furnished gas for commercial and domestic use. The remaining gas wells were connected only for use as field fuel for the exploratory operations going on at that time.

"During the four years 1922 to 1926, my work included a study of the subsurface geology of the Texas Panhandle area. In this period many exploratory test wells were being drilled in widely scattered locations throughout the Texas Panhandle area. The results of these tests and a study of the well records and samples of the drill cuttings obtained from them revealed the fact that the Texas Panhandle oil and gas field was confined to and controlled by a very large anticlinal structure or upward fold in the rock beds having an axis extending from southeast to northwest through Wheeler, Gray, Carson, Hutchinson, Potter, and Moore Counties, Texas, for a distance of more than 100 miles

"This anticlinal structure was found to be underlain by an irregular range of mountains composed of igneous rock upon which had been laid down sedimentary rock beds of Pennsylvanian and Permian age. These sedimentary beds included several irregularly distributed pay formations containing oil and gas and salt water. Along the apex of this fold, gas has accumulated in tremendous quantities; while along its northeast flank and in local low areas near its apex and on its southwest flank large concentrations of oil are found in the several pay formations which produce gas higher on the structure. Lower on the anticlinal structure, down dip from the oil producing area, salt water was encountered in the pay formations.

"Wells encountering salt water instead of oil and gas are called dry holes by oil and gas men. The extent of the field was defined by the salt water wells occupying a low structural position around the margins of the field. During this exploratory period, the Gulf Oil Corporation extended their lease holdings in this area on my recommendations until they included approximately 200,000 acres. Also upon my recommendations they drilled several exploratory test wells and contributed money or material to the drilling of many more scattered throughout the field.

"The second phase of my work in the Texas Panhandle oil and gas field may be called development work. It followed immediately after the exploration phase already discussed and covered the years 1926 to 1927. At this time oil pipe lines were built to the Texas Panhandle field connecting it to the trunk pipe line systems of the larger oil companies and hundreds of oil and gas wells were drilled in this field.

"During this period, the Gulf Oil Corporation completed between 150 and 200 oil and gas wells there and it became my duty to furnish geological information to guide the drilling and production department in the completion of these wells. This work included recommendations as to the proper points at which to set casing in the wells and the furnishing of information as to the probable depths at which gas, oil and salt water might be expected in order that the completion of the wells should be as efficient as possible. My work also included the making of recommenda-

tions as to the locations of wells drilled in semi-proven areas within the field. This work was undertaken to avoid as much as possible the drilling of dry holes and also gas wells which could find no market connections at that time.

"My work during both the exploratory phase and the development phase necessitated that I keep constantly in touch with the drilling activities of all operators in the field, in order that I might keep abreast of current additions to geological information that would be of practical value in guiding the program of the Gulf Oil Corporation.

"The third phase of my work for the Gulf Oil Corporation may be referred to as the geophysical phase. During the years 1928 and 1929 I was given the assignment of correlating the subsurface geology of the Texas Panhandle and of West Texas with geophysical exploration work which was being carried on by them at that time. This included a magnetometer survey which covered almost the entire area from the north line of the Texas Panhandle region southward into southwest Texas. In doing this work, it was again necessary for me to study the logs and samples of the drill cuttings secured from the many test wells scattered throughout this large area.

"In August 1929 I resigned my position with the Gulf Oil Corporation and opened an office as independent consulting geologist. Since that time I have been engaged continuously in doing consulting work on geological problems in connection with oil and gas. I estimate that approximately 95 per cent of this work has been confined to the Texas Panhandle area.

"My work as a consulting geologist in this area covers various activities.

"I am called upon to make locations for oil and gas wells and for recommendations as to casing points and drilling depths of these wells.

"I frequently prepare valuation reports on oil and gas properties. Such reports are used by prospective buyers of such properties or owners who wish to make sales of such properties or banks who make loans on them. My valuation reports are also required by individuals or estates owning

oil and gas properties in connection with their income taxes or estate taxes.

"I also prepare appraisals for the use of corporations in their reports and applications to the Securities and Exchange Commission in connection with matters of financing stock or bond issues.

"My work also includes the preparation and presentation of technical evidence before various commissions and courts of law as to conditions existing in the Texas Panhandle oil and gas field.

"In order that I may carry on this varied work and be of service to my clients I must of necessity keep an up-to-date file on the development activities of the field. At the time I left the Gulf Oil Corporation in the year 1929, they were kind enough to give me a complete file of information on all the wells drilled in the Texas Panhandle field up to that time. I subscribe for the services of the Dwight Well Log Service of Amarillo, Texas, from whom I obtain copies of logs of all the wells drilled in the field. This I supplement with information obtained from many of the operators in the field, including both independent operators and major oil and gas companies. This includes information on oil and gas production and the geology of the field. Some of the geological departments of the major oil companies maintain collections of samples of the drill cuttings from most of the wells in the field. I have access to these collections and have examined thousands of well cuttings from wells in all portions of the Texas Panhandle field in connection with my study of the geology of the area.

"I might explain that these samples of well cuttings are taken from the wells at regular depth intervals, usually every five or ten feet, and put in little cloth bags which are labeled with the name of the well and the depth from which the samples came. These bags of samples are brought to the geological department of the oil or gas companies, where they are washed, dried and put into one-ounce bottles. These bottles are labeled as to the name of the well and the depth of the samples, and aranged in boxes in proper sequence from the top to the bottom of the well. Examining these, one can get at a glance a quick picture of the formations

which any particular well penetrated, or one can make a detailed microscopic study of the whole geologic section as revealed by these samples of the drill cuttings.

"These samples are accessible to me partially by virtue of my personal friendship with the geologists of the major oil and gas companies. However, I am able to cooperate and contribute to them information and samples from the wells drilled in the field by numbers of my clients. In many cases small independent operators do not keep collections of drill cutting samples, but are willing to instruct their drillers to take the samples as the wells are being drilled, sack them and mark them properly and turn them over to me or the scouts or geologists of the major companies who maintain a sample exchange so that all of the companies cooperating may obtain samples not only from their own wells but from any other wells in the field which are of particular interest to them. The sample exchange bureau referred to is managed by E. V. Dwight, who has headquarters in the Herring Hotel, Amarillo, Texas."

The witness then identified Exhibit 187 which was received in evidence, and which is a pressure contour (isobar) map of the Texas Panhandle Field, the various pressure bands of which are set out in different colors.

The witness explained that the heavy line around the outside of the map represents the outline of the Texas Panhandle Gas Field as determined by the Railroad Commission of Texas. There are some additional areas included along the northeastern flank of the colored portion of the map which produce oil, but which are not considered as part of the gas field. The colored pressure bands represent 20 pound differentials in pressure.

The witness further explained the map, Exhibit 187 (Vol. 68, pp. 9976-9987), as follows:

"Introducing Exhibit No. 187, entitled 'Texas Panhandle Gas Field Rock Pressure Map, May 1939.'

"This exhibit portrays the extent of the Texas Panhandle gas field. Its border is outlined by heavy black lines as drawn by employes of the Railroad Commission of Texas on a map issued by them in the summer of 1937. Nothing has occurred in the development of the field since that time which materially changes this outline and it will serve our present purposes in defining the extent of the field.

"This exhibit further portrays by 20-pound interval contours and colored bands the rock pressure conditions existing in the Texas Panhandle field as of July 31, 1939. I drew these contour lines and colored bands, using the official well-head gauge pressures recorded by the Railroad Commission of Texas during the summer of 1939, purporting to show the rock pressure conditions existing in the field as of July 31, 1939.

"The following legend is used, as indicated on the exhibit, each color representing well-head gas pressure conditions as follows:

	Pounds
Gray	0-200
Orange	200-220
Dark Blue	220-240
Pink	240-260
Red	280-300
Purple	300-320
Yellow-Green	320-340
Light Blue	340-360
Brown	360-380
Salmon Pink	380-400
Yellow	Above 400

"It will be noted that the area colored gray, where well-head gauge pressures are 200 pounds or less, are confined to or are adjacent to those portions of the field which produce oil; while the areas colored yellow, where well-head gauge pressures are 400 pounds or above, are situated in localities remote from the oil producing portion of the field."

Q. Right there, Mr. Thompson, you might explain by reference to the map where the oil producing formations in the field are.

A. Most of the oil producing portions of the field lie on the northeast side of the field with unimportant exceptions, such as east central Carson County where there are two oil wells and a few down in south central Gray County.

Q. You have a number of little dots on the map, Exhibit 187, both within the gas field area and without the gas field area. What do those dots represent?—all up and down the northeast flank of the structure there.

A. Those dots represent oil wells. Also I call your attention to the fact that there is an area in northern Moore County which produces some oil.

Q. You say those dots represent oil wells. Do those dots within the confines of the gas field also produce gas as well as oil?

A. Yes.

Q. All right.

A. "Originally, the entire area of this field had a pressure of 430 pounds and would, therefore, have been colored solid yellow, using the above color scheme. The pressure differential in the field, as indicated on this exhibit, is the result of progressive depletion of the gas reserves of the field due to gas withdrawals coincident with the production of oil and gas withdrawals for gas pipe line use.

"In the early life of the field, gas was largely regarded as a nuisance, handicapping the development of oil production. Since there was no market outlet for the gas itself, the result was that it was wasted in tremendous quantities during the early production history of the field. The earliest major oil producing areas to be developed in the field were the Borger area in south-central Hutchinson County and the Lefors area in central Gray County.

"In these two areas, gas was encountered in pay formations above the oil bearing formations. Little interest was taken in conserving this gas. It was frequently allowed to flow from the hole along with the oil and was, thus, entirely wasted to the air. This gas produced with oil was known as casinghead gas.

"This situation gave rise to what is now known as our casinghead gasoline industry in this field. The otherwise wasted gas could be utilized by casinghead plants which removed its gasoline content and popped the residue gas

into the air. Since enormous amounts of gas were thus being wasted, the carbon black industry then moved into the field to utilize the otherwise wasted casinghead gasoline plant residues for the manufacture of carbon black.

"These two industries were, therefore, firmly established and used tremendous quantities of gas from the oil producing areas of the Texas Panhandle field before the major gas pipe lines were ever built to convey gas to distant cities for industrial and domestic use. The result of these early withdrawals from the oil field areas was the establishment of the pressure differential picture set forth in this exhibit. Without question, there has been a tremendous drainage of dry gas from that portion of the field which produces dry gas only to the low pressure oil producing areas due to this long-established differential in pressure. That drainage has continued progressively from year to year and is effective today.

"Estimate of Reserves.

"Introducing Table A of this exhibit entitled:

> "Estimated Original Recoverable Reserve of the Panhandle Field at a Pressure Base of 16.4# per square inch at Assumed Wellhead Abandonment Pressures of 0, 25, 50, 75, 100 and 125 Pounds.

"In arriving at my estimate of the original gas reserves of the Texas Panhandle gas field, I have assumed that the estimate of the Railroad Commission of Texas of 1,461,936 acres for the total proven gas acreage in the field is substantially correct. I have divided this gas acreage into two classes:

"Commercial	1,035,146 acres
"Marginal	426,790 acres
"Total	1,461,936 acres

"Mr. C. J. Peterson's Exhibit No. 206, shows substantially my ideas as to the location and extent of these two

classes of gas acreage in this field. This exhibit expresses so nearly my own ideas in this matter that if I prepared a map myself setting forth my ideas on the subject, it would be so nearly a duplication of Mr. Peterson's map that I do not consider it worthwhile to do so.

"Estimate of Gas Reserves:

"Following is my estimate of the original gas reserves of the Texas Panhandle gas field at zero pounds absolute:

Commercial—1,035,146 acres at 17,514 Mcf. equals 18,129,547,044 Mcf. at 0# Abs.

Marginal—426,790 acres at 5,000 Mcf. equals 2,133,950,000 Mcf. at 0# abs.

Total—1,461,936 acres 20,263,497,044 Mcf. at 0# Abs.

"In estimating the gas reserves of any field, one of two methods is generally employed by geologists and engineers.

"One, usually referred to as the 'pressure decline' method, makes use of data setting forth rock pressure declines as compared to total withdrawals. This method is very satisfactory for use in estimating the reserves of small fields in which the thickness and porosity of the pay formation is comparatively uniform. However, it cannot, in the writer's opinion, be used with any degree of satisfaction in the Texas Panhandle gas field which involves an area of nearly 1,500,000 acres under which the porosity and thickness of the pay formation are exceedingly variable.

"Another method, therefore, has been applied by the writer in determining reserves of gas in this field. This method, known as the 'pressure porosity' method, takes into account the volume of effective pore space in the reservoir rock, as indicated by estimated pay thickness and porosity conditions.

"Commercial Gas Acreage

"In arriving at the estimated gas reserves under the class of acreage referred to as 'commercial acreage,' the following formula has been used:

$$\frac{43560 \times 471 \times 70 \times 20 \text{ per cent}}{16.4} = 17{,}514 \text{ Mcf. gas per acre.}$$

"In the above formula.

43560 equals Number of square feet in one acre.

471 " Average original bottom hole pressure expressed in pounds per square inch.

(430 plus 13 plus 28 equals 471)

430 equals Original well head gauge pressure.

13 equals One atmosphere at barometric reading of average atmospheric pressure of field in pounds per square inch.

28 equals Weight of column of gas in pounds per square inch. (Bureau of Mines Formula).

70 equals Average feet thickness of pay formation in field.

20 per cent equals Average porosity of pay formation in field.

16.4 equals The pressure base expressed in pounds per square inch at which the gas is measured.

"To arrive at the average pay thickness of 70 feet, indicated above, a study has been made of hundreds of well records from gas wells in the field.

"The average porosity of 20 per cent is the result of studies made by myself and other geologists in this and other gas fields.

"Marginal Gas Acreage

"Experience to date forces me to conclude that as a whole the marginal area of the Texas Panhandle gas field is underlain by comparatively thin gas pay formations of low permeability and I seriously question the economic expediency of attempting any wide-spread drilling campaign there.

"This marginal gas area includes that portion of the field where I anticipate that wells of less than 5,000 Mcf. natural open flow volume capacity would be completed if drilled. A study of the completion data obtained from the records of the wells drilled in the marginal area to date reveals that

they were either very small gas wells or dry holes, with the exception of a few instances where small oil wells were completed. Considering the information obtained from the records of these wells, I am forced to conclude that the marginal area is one of very low potential gas productivity where perhaps only two or three million cubic feet of gas per acre will be found. However, since information is rather incomplete in certain portions of this area due to lack of drilling, I have assigned a judgment figure of an average of 5,000 Mcf. of gas per acre to the reserve of the marginal area. This, I am confident, makes due allowance for instances where possible future exploratory drilling may result in encountering larger open flow volumes than I anticipate at the present time.

"The pressure factors shown in Column 3 on Table A of this exhibit are arrived at by the application of a formula worked out by the United States Bureau of Mines and published on Page 167 in 'Bureau of Mines—Monograph 7,' together with Table 37, Page 156 of the same publication. By this formula, the following ratios between gas at zero pounds absolute and the various assumed well-head gauge abandonment pressure in this field are shown as follows:

Pressure factor for 0= well-head gauge $=1-\frac{14}{471}=.97028$

(14 = bottom hole pressure when well-head pressure = 0)

Pressure factor for 25= well-head gauge $=1-\frac{40}{471}=.91507$

(40 = bottom hole pressure when well-head pressure = 25)

Pressure factor for 50= well-head gauge $=1-\frac{67}{471}=.85775$

(67 = bottom hole pressure when well-head pressure = 50)

Pressure factor for 75= well-head gauge $=1-\frac{94}{471}=.80042$

(94 = bottom hole pressure when well-head pressure = 75)

Pressure factor for 100= well-head gauge $=1-\frac{120}{471}=.74522$

(120 = bottom hole pressure when well-head pressure = 100)

Pressure factor for 125= well-head gauge $=1-\frac{147}{471}=.68790$

(147 = bottom hole pressure when well-head pressure = 125)

(When well-head gauge pressure = 430 pounds, the bottom hole pressure = 471 pounds)

"It will be noted that Column 5 on Table A of this exhibit indicates that I have used a recovery factor of 90 per cent. It is generally recognized by geologists and engineers that a 100 per cent recovery of the gas from any given field is impossible. I believe that the use of a recovery factor of 90 per cent in estimating the recoverable reserves of the Texas Panhandle gas field is entirely justified.

"The tremendous area of the field and the extreme variation of conditions in the pay formations must be taken into consideration.

"Incomplete recoveries of gas from the field may be anticipated for various reasons which include the trapping of gas in pay lenses, water pollution from both bottom hole water and upper water improperly shut off due to imperfect casing.

"The plugging of wells by salt precipitation, the rusting through of casing or any other occurrences leading to insurmountable mechanical difficulties, will also contribute to incomplete recovery of gas from the field.

"Contributing to incomplete recovery of gas from the field is the fact that at any given well-head abandonment pressure of the wells in the field a higher pressure will exist at points between the wells. This being the case, the gas creating this higher pressure between the wells will not be recovered at any assumed well-head abandonment pressure. For example, when the wells in the field have reached a pressure of 125 pounds, it is reasonable to assume that some areas in the field between the wells might have a pressure of 150 pounds or 175 pounds or higher, representing a substantial volume of unrecoverable gas should the field be abandoned at 125 pounds well-head pressure. A like condition would exist, relatively speaking, at any other assumed abandonment pressure.

"It is reasonable to assume that large portions of the marginal area will never be drilled due to the fact that such development would be economically inexpedient because of the small open flow volume capacities to be anticipated in the drilling of wells in this area. The result will be a very much wider well spacing in the marginal area than in the com-

mercial portion of the field, resulting, obviously, in incomplete recovery of the gas reserves of the marginal area. This effect will be increased by the low permeability which our experience indicates to be existent in the marginal area.

"It will be noted that Column 7 on the exhibit sets forth total production from the Texas Panhandle field to the date January 1, 1939. Mr. Peterson's Exhibit No. 206 explains the method of arriving at this figure."

The witness further testified (Vol. 69, pp. 9990-9991) as follows:

A. Presenting Table "A" in exhibit 207. "Estimated Original Recoverable Reserves of the Panhandle Field at a Pressure Base of 16.4# per square inch at assumed wellhead abandonment Pressures of 0.25, 50, 75, 100 and 125 Pounds.

Assumed Abandonment Pressures	At 0 Lbs. Abs.	Pressure Factor	Product	Recovery Factor		Original Recoverable	Production to 1-1-39	Recoverable 1-1-39
0# Gauge	20,263,497,044 Mcf.	x .97028	19,661,265,912	M x .90	equals	17,695,139,321	7,156,238,820	10,538,900,501
25# Gauge	20,263,497,044	x .91507	18,542,518,240	M x .90	"	16,688,266,416	7,156,238,820	9,532,027,596
50# Gauge	20,263,497,044	x .85775	17,381,014,589	M x .90	"	15,642,913,130	7,156,238,820	8,486,674,310
75# Gauge	20,263,497,044	x .80042	16,219,308,304	M x .90	"	14,597,377,474	7,156,238,820	7,441,138,654
100# Gauge	20,263,497,044	x .74522	15,100,763,267	M x .90	"	13,590,686,940	7,156,238,820	6,434,448,120
125# Gauge	20,263,497,044	x .68790	13,939,259,617	M x .90	"	12,545,333,655	7,156,238,820	5,389,094,835

On cross examination the witness (Thompson) testified that the reserve estimate which he had given could not be called either a maximum or a minimum estimate but that he did think it was a fair estimate and one that he thought was right; that he could have done several things that would have made a smaller estimate, for example, he could have used a higher recovery factor but he did not do so because he did not think it was justified and neither did he think a lower recovery factor would be justified, and that if he had thought so he would have used a lower recovery factor. He used the recovery factor that he thought was right. The witness does not think that, rationally, he could have made the estimate either higher or lower. (Vol. LXXV, p. 10972, 10973.)

The witness further testified that open flow of the wells was a good criterion of the relative amounts of gas in place and that although he did not do so, it was not unreasonable to estimate reserves on the basis of open flow of the wells because sustained high open flows indicated a high porosity. (Vol. LXXVI, p. 11153, 11154.)

The witness testified on cross examination that he was likely too generous in his estimate as to the gas in place in the marginal area and that the structural situation in such area was such that to him it was unthinkable that that area contained much gas. (Vol. LXXVI, p. 11140.)

The witness was then referred to the marginal area (colored gray) on Peterson's map contained in Exhibit 206, in Moore County, where only a few wells had been drilled, and was asked if that area would probably not prove to be highly productive. The witness answered that he had rather definite information about the structural situation in the particular area referred to and that it was going to be too low to be highly productive, but on the other hand that he had assigned a higher acre content to the marginal area to take care of a situation where larger wells might be discovered. That some wells near the edge of the field are highly productive because they are far enough up on the struc-

ture to make them so, but there is a sudden rapid dip in the producing formations at the edge of the field. Experience through the history of the field has indicated that you will run out of high productivity almost immediately. (Vol. LXXVI, pp. 11141-11143.)

Witness further testified that the marginal or gray area, as shown in Exhibit 206, in Moore County, was generally low structurally and that this had been determined from geological information from small wells drilled within the area as well as dry holes drilled outside of the area and that although large wells are sometimes found near the edge of the field and near the edge of the gray area, because they are located rather high structurally, still these wells do not indicate that the marginal area generally has large gas reserves because its structural position is too low for this to be true.

(Vol. LXXVI, pp. 11142-11148.)

On cross-examination the witness testified that it was still necessary to apply a recovery factor, even though the field was not producing down to zero pounds wellhead. In other words, wherever you stopped producing, whether at 25 pounds wellhead or any other figure, there would always be areas in the formation between the wells higher in pressure than the abandonment pressure at the wellhead. (Vol. LXXV, pp. 11096-11098.)

The witness also reiterated the statements contained in his direct testimony with respect to loss of gas through mechanical troubles, such as caving or salting up of the formations and many other things that can happen to gas wells, which would dry up the outlets and result in the non-recovery of gas which would otherwise be recovered by the well, all of which would make it impossible to obtain a 100 per cent recovery. (Vol. LXXV, p. 11108.)

The witness, upon being cross-examined on an assumed 25 pounds abandonment pressure, testified that at this abandonment pressure you would have approximately 6 per cent of the original gas left in the reservoir but that this assumes that you had an equal pressure of 25 pounds all over the

field, not only at the wellhead but back away from the wellhead where it is known there would be substantially higher pressures and that the gas represented by those substantially higher pressures would not be recovered if the wells in the field were abandoned at 25 pounds. There must be something deducted from the total reserve in order to get the recoverable figure which calls for the application of a recovery factor at any assumed wellhead abandonment pressure. The witness then referred to an estimate of reserves as shown in Schedule A, Exhibit 207, wherein he arrived at a figure of 18,542,000,000,000 cubic feet plus, which is absolutely all the gas there is in the field above an assumed 25 pounds abandonment pressure. He then stated that you would not get every foot of that gas because there will be pressures in the field that will be substantially higher than the 25 pounds at the well, and therefore this calls for the application of a recovery factor. (Vol. LXXV, pp. 11101-11104.)

The witness also testified that in some fields which were influenced by water drives and where the encroachment of water causes the blocking off of large amounts of gas, recovery factors as high as 40 or 50 per cent are sometimes used and that although he did not anticipate any great loss of recovery on account of water in this field (Texas Panhandle Field), still there would be local losses due to water pollution from wells but not nearly as great as is encountered in the water-drive field, and also that although there were many reasons why all of the gas would not be recovered at any given abandonment pressure that one of the most important reasons is the fact that the gas pressure will always be higher out in the formation between the wells than it is at the well. (Vol. LXXV, pp. 11107, 11108.)

The witness discussed also the matter of bottom hole water and that as pressures go down water encroachment will become a great deal more important and also as the equipment in the wells gets older water troubles will develop to a more serious proportion. All wells reaching low pressures will not eventually develop water troubles but the water that is included in the field will probably be more operative in low pressures than in high pressures and water encroachment probably more effective as pressures get lower. (Vol. LXXV, pp. 11111-11113.)

Determination of Thickness of Gas Pays

The average pay thickness of 70 feet in the best commercial area of the field was utilized by witness in making his computations as to reserves and was based upon a study made by him of hundreds of gas wells in the field. (Exhibit 207, p. 8, Vol. LXVIII, p. 9983.)

The witness on cross-examination stated that he had used nearly 600 wells in determining his average pay thickness. (Vol. LXXV, p. 11034.) The determination was made in the early part of 1938. The figure arrived at for the average of all wells utilized was 69.86 feet but for convenience in computing his reserves he considered the pay thickness to be 70 feet. Pay thicknesses cannot be determined exclusively from well logs. The card index file kept by witness and which was utilized by him contains more information frequently than do the wells logs. (Vol. LXXV, pp. 11035-11036.) Witness explained how a determination of pay thickness was made from a study of well logs and from information he had gathered from time to time and shown on his card index system, and where these two sources of information were not clear, by discussing the matter with drilling superintendents, drillers on the rig and others who might have definite information about a particular well. With all of this information assembled it is then a matter of taking the pay formations in which gas was encountered and the distance of each formation in which gas was encountered, and totaling them up in order to get the total pay thickness for any given well. (Vol. LXXV, pp. 11041-11050.)

The witness was cross-examined at length regarding numerous wells with respect to the data contained on the cards taken from his card index file, and from the information shown on these cards the witness computed the pay thickness in a number of wells. He then stated on redirect examination that he could not hope to, and did not attempt to, keep all of the relative information with regard to pay thickness or other matters readily accessible in his cards, but that he did try to keep a card on every well drilled in the field, although there were some wells upon which he did not have cards, but these cards merely represented the beginning point of his investigation of any particular well, whether for pay thickness or any other matters; that he did not rely

entirely upon his card index file, nor upon wells logs for determining pay thicknesses or other matters, but gathered all information he possibly could from reliable sources available to him. (Vol. 94, pp. 14357-14362.)

The witness did not consult with Peterson with respect to his pay thickness determination except as to some wells of Texoma Natural Gas Company, the drilling of which had been supervised by Peterson. (Vol. LXXV, p. 10964.)

Thompson stated on direct examination that in the Texas Panhandle Field natural gas occurs in four separate geological formations, as follows:

1. Red Bed, which is of negligible importance.
2. Brown Dolomite, which is by far the most consistent and important gas pay in the field.
3. White Lime, which is of relatively small importance.
4. Granite Wash, which is locally quite important, but is not consistent in its occurrence in productivity and does not cover nearly as large an area as does the Brown Dolomite gas pay.

In order to portray the great variability of conditions under which oil, gas and water are found in the Texas Panhandle area, the witness prepared two graphic cross sections showing conditions found in the various wells included in said cross sections. These cross sections are marked Exhibits 208 and 209, respectively.

Exhibit 208 extends approximately from south to north through the lease holdings of Canadian, and Exhibit 209 extends from a point near the western end of the gas field through the lease holdings of Canadian. Their exact positions in the Texas Panhandle Field are shown on Exhibit 187 by green lines connecting the various wells shown in the cross sections.

These two exhibits are described in detail at pages 11 to 22 inclusive on Exhibit 207 and also in Volume LXIX, pages 9993-10019.

Briefly, these exhibits show the producing formations in the wells designated in each of the exhibits, and show the

respective formations in which gas, oil or water was encountered in those wells. They also show the type of gas pay formation in which oil, gas or water was encountered; that is, whether in Brown Dolomite, White Lime, Granite Wash or Red Bed. They also show the thickness of the gas pays encountered as determined from well logs and the card index file of witness Thompson, but do not necessarily show all of the information possessed by Thompson and utilized by him in the determination of sand thicknesses.

Thompson stated that there is extreme variability in the thickness and productivity of the various pay formations encountered and that one or more of these pay formations are absent in all of the wells shown. The cross-sections show that the Brown Dolomite gas pay formation is by far the most consistent and productive of any of the gas pays encountered.

Determination of Effective Porosity

On cross-examination witness reiterated that he had arrived at an average porosity of 20 per cent and that this figure was used in his reserve estimate. (Vol. LXXV, p. 11012.) It was his opinion that a 20 per cent porosity figure was the most accurate figure that could be reached. (Vol. LXXV, pp. 11053, 11054.)

Witness arrived at a determination of the average porosity through the examination of well cuttings, well logs, well cores, information that he could get from producers, etc. (Vol. LXXV, pp. 11001, 11002.)

Well cuttings are fragments of rock bailed out of the drilling wells—the samples of the cuttings can be bailed out when going through the gas pay if the open flow volume is not too great and cuttings are blown out of the hole from the gas pay in large wells. Sometimes big pieces of rock are blown out with good porosity in them. (Vol. LXXV, pp. 11002-11004.) Witness has examined a great many of the well cuttings under microscope (Vol. LXXV, p. 11010) and has examined many oil well cores under microscope covering a period of years. (Vol. LXXV, pp. 10995-10996.) The information obtained from the examination of oil well cores and the porosity determinations therefrom (Exhibits 216, 217; 218) has corroborated witness' previous ideas as to

porosity. Witness is permitted by the major oil companies to consult their collections of cuttings very freely at any time he desires. (Vol. LXXV, p. 11005.) The Gulf Oil Corporation, for example, had samples of well cuttings aggregating more than 250,000. (Vol. LXXV, p. 11009.) It can be determined where the cuttings are coming from that are blown out of the hole during drilling operations. (Vol. LXXV, p. 11006.)

Volume of Gas Produced from the Texas Panhandle Field from Beginning of Production to December 31, 1940.

Thompson did not utilize the gas withdrawal figures in his estimate of gas reserves. However, Schedule A of Exhibit 207 does show the production of gas up to January 1, 1939, which aggregates 7,156,238,820 Mcf. The witness deducted this figure from his original recoverable reserves at various assumed abandonment pressures in order to show the remaining reserves recoverable as of January 1, 1939.

Witness stated on cross-examination that he had accepted the Cotner and Crum figures of withdrawals (Exhibit 215) up to 1932, and as to subsequent withdrawals, had accepted Peterson's figures. (Exhibit 206, Vol. LXXV, p. 10975.) He accepted Cotner's figures because he had helped Cotner in the compilation of the figures and consulted with him very freely in the preparation of the Cotner paper, and he also knew the very great detail that Cotner went into in assembling his data and he was confident that his figures were approximately correct; and that such figures were accepted by the witness as the best available figures obtainable. In his opinion they could not be inaccurate enough to make any very great difference in the present remaining reserve estimate of the field. (Vol. LXXV, pp. 10977-10978.) The witness also testified that he had assisted Peterson in compiling his figures of withdrawals; that he knew that Peterson had spent a lot of time and very great care in the compilation of the figures and he was willing to accept them as being accurate. (Vol. LXXV, p. 10980.) He knew that it was necessary and that Peterson did convert some of the withdrawal figures from different pressure bases to a 16.4

pounds base, which is the base upon which the figures are given. (Vol. LXXV, p. 10987.)

The witness believes that you can estimate gas blown into the air with a fair degree of accuracy and he thinks Cotner did so. He was thoroughly familiar with the field and the witness has confidence that his work was sufficiently accurate that he does not hesitate to use it. (Vol. LXXV, p. 11094.)

J. D. THOMPSON, JR., also testified (Vol. 75, pp. 10994-10998; 11013-11015; 11033-11037; 11085-11086; 11099-11105) as follows:

By Mr. March:

Q. Did you examine any such cores of the company?
A. No, sir.
Q. Is that a pretty expensive process, taking those kind of cores?
A. I presume it would be. I don't know much about it.
Q. Did you ever see one taken?
A. No.
Q. Did you ever see any kind of a core taken?
A. I think I have seen cores taken.
Q. Where was that?
A. In the Panhandle field.
Q. Oil well cores?
A. Yes.
Q. Did you ever see any gas well cores?
A. I don't believe I ever have.
Q. Do you know of anybody that ever has?
A. I don't recall having anybody tell me that they had.
Q. Where were these oil well cores from?
A. From various wells in the Texas Panhandle field. I can't specify any particular one.
Q. Could you specify a particular one if I gave you time to check up on it?
A. No.
Q. Did you examine those cores under a microscope?
A. Yes.
Q. Do you have a record of it?
A. No.

Q. About how many have you seen?

A. Oh, I wouldn't know. Over a period of years I have seen a great many but I couldn't say how many?

Q. About how many have you examined?

A. That is what I say, that I can't remember.

Q. You have no record of any examination of an oil core?

A. That is correct.

Q. Do you know the process by which the cores are taken, the different processes?

A. They use core barrels.

Q. That is not the most effective process, is it?

A. I am not an expert on the technique of taking cores.

Q. Do you know how to direct somebody to take a core?

Mr. Spencer: If he isn't an expert, I don't see how he could direct anybody.

Mr. March: He can say so.

Mr. Spencer: Why repeat the same question?

Mr. March: I want to be sure. I want to have it in the record just exactly how it is.

The Witness: No, I wouldn't attempt to direct anybody in doing that.

By Mr. March:

Q. Have you in your office a core of any well from anywhere?

A. I used to have two or three pieces of core. I don't remember whether I still have them or not.

Q. Were they of oil wells?

A. I don't even remember what wells they came from. I picked them up as showing certain conditions which were interesting to me. I presume they were from oil wells, however, they were not from the pay formation.

Q. They were not from the pay formation?

A. No.

Q. Did you look at them under a microscope?

A. I looked at them under a hand lens.

Q. Did you make any notes on your observations?

A. No.

* * * * *

Q. Can you take any given gas well and tell me what the porosity is in that gas well specifically?

A. That would be rather hard to do.

Q. How's that?

A. I don't believe I can.

Q. Have you any working papers where you have computed the porosity upon individual gas wells in the Texas Panhandle field?

A. No.

Q. Have you ever seen any such calculations?

Mr. Keffer: If the Examiner please, just on that—I don't know that it makes a whole lot of difference. Mr. Thompson explains in his exhibit very clearly and rather carefully the basis of reserves estimated in the field by him in which he takes as one of his factors a 20 per cent porosity throughout the commercial area in the field. There may be wells that have a greater porosity and there may be some others that have less. That is almost certain to be true. I think he has already stated that he made no calculations on individual wells in order to get that average, but that is determined by an examination of cuttings and all other information that he could get.

For that reason I feel as though the question has really been answered in his written statement so far as that is concerned.

Mr. March: I will proceed on—

Mr. Keffer: How's that?

Mr. March: I won't stay on that point any longer; however, I do want to explore it enough to know what it is.

Q. Now, Mr. Thompson, I note that you—you might answer my question. You might answer the question pending here. Have you ever seen any porosity determinations on individual wells in the Texas Panhandle gas field?

A. Yes.

Q. Whereabouts?

A. I have arrived at what might be called porosity myself by calculation.

Q. All right, can you tell me the porosity on any given well in the Texas Panhandle field?

A. No.

Mr. Spencer: Are you talking about gas wells?

Mr. March: He said no, that's all I want. Gas wells is what I'm talking about, yes.

Q. Now, let's see, now, have you ever seen anyone else arrive at the porosity of individual gas wells in the Panhandle field of Texas?

A. Yes.

Q. Who?

A. Peterson.

Q. Peterson?

A. Yes.

Q. Have you ever seen his tabulation as to porosity of individual wells?

A. Yes.

Q. Well, where is it?

A. I don't know. It isn't here, I am sure.

Q. That's the only one you have ever seen?

A. It is all that I recall at the moment.

Q. Sir?

That's all that I recall.

• • • • •

Q. I hand you a copy of Mr. Peterson's working paper and refer you to Page 10 and ask you if that is the well, Canadian River Gas Company Seay 1?

A. Yes.

Q. Will you give his thickness?

A. He gives a thickness of 52 feet.

Q. Now, Mr. Thompson, did you use this well in arriving at your pay thickness calculation?

A. I don't remember.

Q. Can you tell me any particular well that you used in arriving at the 70 per cent pay thickness?

Mr. Spencer: 70 what?

Mr. March: 70 feet pay thickness.

The Witness: I can't be absolutely certain.

By Mr. March:

Q. Well, have you a list of the wells that you used in determining your pay thickness?

A. No.

Q. There isn't such a list in existence?

A. No.

Q. How many wells did you use?

A. Nearly six hundred.

Q. There isn't any possible way for me to check upon the wells that you used?

A. No.

Mr. Spencer: How long ago did you do that work, Mr. Thompson?

The Witness: In 1938. In the early part of 1938.

By Mr. March:

Q. Did you then have notes on all these wells individually?

A. At the time I prepared the estimate I had a list of the wells which I assembled from my card file. I don't know that I had any further notes than that.

Q. Would you say that your 70.1 pay thickness that you arrived at was a pure judgment figure?

A. No. I didn't arrive at 70.1.

Q. What did you arrive at?

A. I arrived at 69.86, but I used 70 just for convenience. I think one must use his judgment in interpreting the pay thickness of the individual wells; so there is a judgment factor to that extent.

Q. You couldn't take the logs, then, of Canadian River and—driller's logs—another geologist couldn't go through them and get the same answer that you got just by looking at the logs?

A. I have explained to you that my card file on Canadian River carries a good deal more information than is contained on the logs. I found that the information on them was inadequate in a number of cases.

Q. So it wouldn't be safe to rely just on those logs and tabulate them as to pay thickness?

A. No, sir.

Q. Could you rely upon them in any case?

A. Now, just what case, for instance?

Q. I mean any particular case, any case. Just take those logs—suppose you take Canadian River's logs—could you rely upon them for any check?

Mr. Spencer: Any case or any purpose?

Mr. March: I mean in the case of any particular well or wells or logs.

Mr. Spencer: Rely upon them for what purpose?

Mr. March: I mean rely upon any of the well logs to determine pay thickness exclusively.

The Witness: No.

By Mr. March:

Q. So there is no way, then, that I can check your wells, your pay thickness calculations, is there?

A. No.

Q. Did you use the same wells that Mr. Peterson used?

A. No, I am quite sure I didn't.

Q. Well, do you have any idea of how may wells you used in common with him?

A. No.

Q. Would you say less than half or a third? Do you have any idea?

A. I have no idea. I never compared my list with his.

Q. Then you couldn't say whether you used any in common with him, could you?

A. I presume we must have. I know that I used a good many of the Texoma logs or pay thicknesses in Texoma wells, because I considered my information upon them was more accurate than on some of the other wells.

The Trial Examiner: Mr. Thompson, did you say that you have never compared your list with Mr. Peterson's? I thought you testified you had no list.

The Witness: I don't have at this time.

The Trial Examiner: I see.

The Witness: I made a list but I never compared my list with his.

By Mr. March:

Q. The list is non-existent today?
A. That is right.

• • • • • •

By Mr. March:

Q. Isn't one of the most productive areas of the Canadian River Gas Company near the Fritch compressing station?
A. There are some very good wells in that area.
Q. I note that around that area we have pressures of 346, 345, and 342.
A. That appears to be about right.
Q. Now, that being true, the pressures being down considerably there, what makes you conclude that just because the pressures are down in these wells, these oil wells which have penetrated the gas pay in which wells the gas is cased off, that the production is depleted—I mean, the gas is depleted?
A. The original reserve existing in that area has been depleted by the loss of pressure in direct proportion to the loss in pressure.
Q. Then we have here a direct relationship between pressure decline and loss of gas in place, don't we?
A. Yes.

• • • • • •

By Mr. March:

Q. Well, take his original recoverable reserves. What is your figure there at 25 pounds before you apply your recovery factor?
A. Well, they aren't recoverable reserves.
Q. Well, original recoverable, it says.
A. Well, that column you are refering to I believe says "Product," doesn't it?
Q. Well, I was referring to—yes. We'll say "Product" there. I was referring to the other column but I see I should have been referring to this one. What does "Product" mean?
A. I first found the amount of gas in place at zero pounds absolute.
Q. Originally?
A. Yes. Then in order to reduce that to wellhead gauge

pressures it is necessary to apply a Bureau of Mines' formula reducing it from zero absolute pressure in the field to the zero gauge pressure or 25 pounds gauge pressure or any other desired gauge pressure and so I multiplied the original reserve in place at zero absolute by this Bureau of Mines factor, getting a product which shows in Column 4 on Table A.

Q. Yes. It's 18,542,518,240,000.

A. At 25 pounds.

Q. Yes.

A. 18,542,518,240,000 cubic feet.

Q. Now, just above there is another figure which represents, as I see it, the product at zero gauge.

A. At zero gauge, that's right.

Q. What is that?

A. 19,661,265,912,000 cubic feet.

Q. All right, assuming that you would abandon at 25 pounds, you wouldn't produce any more gas, then between 25 pounds and zero is over a trillion cubic feet of gas, isn't there?

A. Yes.

Q. Now, does that amount to 10 per cent of the gas—does that amount to 10 per cent of the product at 25 pounds abandonment pressure?

A. No, it would amount to approximately six per cent, I believe.

Q. Six per cent?

A. Approximately that.

Q. Well, have you computed it?

A. No, I haven't, but 1 trillion is one-eighteenth of 18 trillion and I just made a rough guess. If it were 20 trillion it would be 5 per cent.

Q. Yes. In other words, the amount of gas which would be between zero pounds and 25 pounds at 25 pounds gauge would be approximately 6 per cent of your 18 trillion, which is the figure you have at 25 pounds, is that correct?

A. Yes.

Q. All right, now, there you have 6 per cent that you are going to assume that is in the formations, that you are not going to get out, that you are not going to want to get out.

Now, I ask you, when you pulled down to 25 pounds and still have 6 per cent of your total reserve—that's correct, isn't it—total original reserves?

A. Yes.

Q. —still in place, doesn't that make due allowance for any gas that would be impossible to recover?

A. No, I think you are confused, Mr. March. Now, that figure there we have been discussing—18 trillions plus represents just a mathematical calculation of the total gas existing in the field. I mean the total gas which could be withdrawn from the field, assuming that the field has an equal pressure of 25 pounds all over the field, not only at the wellhead but back away from the wellhead where we know there would be substantially higher pressures. Now, the gas represented by those substantially higher pressures would not be recovered, so it must be deducted from this total to get a recoverable figure.

Q. Yes, but you have 6 per cent there that you are saying that you will never recover, assuming every well goes down to 25 pounds before it is abandoned.

A. Well, that abandonment pressure may be arbitrarily selected at any point.

Q. Well, if we went up higher you would have a larger percentage in place between your zero and 25 pounds.

A. Sure.

The Trial Examiner: Mr. March, aren't you talking about the pressure for the entire field being down to 25 pounds rather than a 25-pound wellhead abandonment pressure?

Mr. March: I am talking about the wellhead abandonment pressure here at 25 pounds. I am saying this, Mr. Examiner: Assuming that every well did go down to 25-pound abandonment pressure, admitting that there would be pressures higher than that out in the formations and still gas left in the formations, that when you have a difference—by abandoning at 25 pounds you leave in the field at least 6 per cent of your reserves and that takes care of the situation instead of having to go ahead and apply another factor to the thing.

Mr. Spencer: Mr. Examiner, I think he has answered himself. Whenever he reduces his reserves to 6 per cent then he must have less than 25 pounds at the wellhead.

Mr. March: I am not going to reduce them. That's just the point. I am glad you brought that up. I am not going to reduce them to zero. I am going to leave them at 25 pounds and abandon them there, and that leaves 6 per cent of my reserves in the field. Now, I want to know why it is necessary to go ahead and apply another 10 per cent there and leave 16 per cent of the reserves in the field.

The Witness: Well, this basic calculation—I'll read the figures: The original reserve in place at zero absolute is indicated as being slightly over 20 trillion; then we make a basic calculation which assumes that you are going to get every foot of gas in the Panhandle field down to 25 pounds abandonment pressure. You multiply that 20 trillion plus by .91507 and arrive at 18,542,000,000,000, and so forth, which is absolutely all the gas there is in the field above 25-pounds abandonment pressure. You are assuming that you are going to get every foot of it.

Now, you won't get every foot of it because we know that there will be pressures in the field that will be substantially higher. Therefore, I feel that it is necessary to add a recovery factor.

By Mr. March:

Q. Yes, but if we abandon down to 25 pounds, leaving 6 per cent of the gas in the field, doesn't that take care of the gas which you couldn't get out if you went down to zero? In other words, here the situation is, Mr. Thompson, as I see it, if you abandon at 25 pounds instead of going back to zero, why, that leaves 6 per cent of the gas in place in the field.

Mr. Spencer: It leaves more than that. That's what he has been testifying.

The Witness: 6 per cent plus.

By Mr. March:

Q. 6 per cent in place in the field?

A. 6 per cent plus—

Q. Just a moment. But if you went down to zero, then you wouldn't have 6 per cent. You could then apply a recovery factor of 10 per cent because you wouldn't have

abandoned above zero, therefore, you couldn't have taken care of any of your gas which you could not recover which was out in the formations.

A. I think I have made my position just as clear as I can make it, Mr. March, on that.

Q. All right, sir. Now, I note with a great deal of interest the statement that Cotner and Crum made. I want to read it to you and see what you think about it.

Mr. Lange: What's the page number?

Mr. March: Page 895, the last paragraph on Page 895.

"As no water is present on structure in the gas pays or directly under them, the Panhandle field will no doubt have an ultimate recovery of all gas in the reservoir with the exception of a very small percentage." Do you agree with that statement?

A. Yes.

Q. All right, sir, that's all I wanted to know.

A. 10 per cent is a very small percentage.

Q. How's that?

A. 10 per cent is a very small percentage.

Q. Yes, but at 25 pounds you wouldn't have 10 per cent in the formations, you would have 16 per cent in the formations, is that correct?

A. Approximately.

Q. Yes, so, therefore, although 10 per cent is a very small amount, when you get up to 16 per cent, that's going up the line, isn't it?

Mr. Spencer: It is more.

The Witness: Yes, but I can tell you just exactly what Cotner meant by that.

Mr. March: I don't want you to tell me what he meant, because I don't think that anybody can tell what any other man means and give an intelligent construction of it.

The Witness: I would like to do that if I may.

Mr. March: I want to subpoena Mr. Cotner in here if there is going to be that kind of testimony permitted.

Witness Thompson also testified (Vol. 76, pp. 11134-11139; 11171-11173; 11242-11245) as follows:

Q. Now, I note that on Mr. Peterson's map he has a heavy line separating the two parts of the field, the east field from the west field. Is there drainage today—movement of gas between the east field and the west field, in your opinion?

A. I would say that there is no effective drainage—no pronounced drainage at this time in either direction.

Q. Would you say that there was slight?

A. Oh, there might be a slight drainage.

Q. Which way is the slight drainage?

A. Both ways—from the area shown colored yellow immediately south of the block fault area indicated in central Gray County. You will note that the contour of the isobars would indicate a drainage from that yellow area northeastward towards Wheeler County and also northwestward toward northwest Gray County.

Q. Do you know what extent that yellow area has changed during the last five years—the pressures there—looking at Exhibit 187?

A. Well, it couldn't have changed much. It is still about 400 pounds.

Q. If there is still about 400 pounds, then there could be little or no drainage, could there?

A. I said it was slight drainage.

Mr. Keffer: May I ask a question there?

Mr. March: Yes.

Mr. Keffer: Did you say, Mr. Thompson—or, would you say, Mr. Thompson, that five years ago that the whole area south of the barren spot in Gray County might not have been 400 pounds? In other words, your yellow area now above 400 pounds may be smaller today than it was five years ago, for example?

The Witness: Well, I am sure that it is smaller than it was five years ago.

By Mr. March:

Q. Now, Mr. Thompson, since there is no effective movement of gas from the east field to the west field and from the west field to the east field, just why in the world do you include the whole field in your estimate of reserves?

A. Well—

Mr. Keffer: I might make just one correction on the question you asked. You said "effective drainage" and I think Mr. Thompson said "pronounced drainage." That may be a distinction without much difference, but there is that difference.

By Mr. March:

Q. Well, is there any effective drainage between those two fields, the east field and the west field?

A. I don't consider that there is at this time. A situation might develop, however, that would make such drainage possible, and since the east field is losing its pressures rather rapidly, I can see the time coming when the pipe lines that are getting their gas from Wheeler County might build an extension over into the west field.

Q. If it moved over to the west field it would kind of equalize the situation, wouldn't it, and prevent any drainage to the east field?

A. Well, it would just add to the gas withdrawals from the west field. Naturally, it would tend to equalize them, having exhausted the gas in the east field, and they moved over to the west, why, that would just tend to exhaust the west field.

Q. Wouldn't gas move very very slowly through this low permeable formation south of the block?

A. Not in my opinion. I think you are right as can be on that.

Q. As I see, to the north here you have, for example, around the Lefors area, you have a very low pressure area which remains low in spite of the fact that there is large pressures around there. Now, if that hasn't built up, why, it is not likely that there will be any drainage from the east field to the west field or vice versa until those pressures build back up, is there?

A. No. Both the west field and the east field are now contributing to the repressuring of this oil producing area shown colored gray in the area immediately north of the block fault in Gray County.

Q. Well, this low area around Lefors here?

A. Yes.

Q. Are the pressures increasing?

A. I haven't made a study of that and I don't know, Mr. March.

Q. I see your isobar map indicates, I believe, here from 200 pounds in that area, about the lowest pressure in the field.

A. Yes, and that area in Wheeler County and in the Borger Sanford area in Hutchinson County are the largest low pressure areas in the field.

Q. If there wasn't any gas wells in the western part of the field, how long do you think it would take the gas wells in the eastern part of the field to drain the gas in the western part of the field, assuming you had the same formations you have got there now—the same structures, the same drilling program in this intervening area— the central area?

A. You mean if there were no oil and gas wells?

Q. No oil and gas wells, we'll say, west of the Roberts and Gray County lines.

A. West of the west lines of Roberts and Gray County?

Q. Yes, and you had the same structure which separates the two fields and you have the same productivity over on the eastern part of the field.

A. The same development conditions as now exists?

Q. Yes.

A. Oh, it would take a long time for the east field to have much effect on the west gas field.

Q. Two or three hundred years?

A. Oh, I don't know. I wouldn't even attempt to measure it in terms of years.

Q. It would be a very long time?

A. Yes, it would be a long time.

* * * * *

Does virgin pressures still exist in the Panhandle field of Texas?

A. I am not sure whether there is any place in the field where you have got absolutely virgin pressure, but there are areas where it is almost virgin pressure.

Q. All right. Now, as I see here, this helium dome is just about a little less than the difference between the nearest well in the Hugoton field and the nearest well in the Panhandle field on the north, is that correct?

A. The Hugoton field is up in Kansas.

Q. Yes.

A. That would be 50 or 60 miles away.

Q. The nearest well between the Hugoton field and the

Panhandle field, the nearest two wells aren't that far away, are they?

A. You didn't ask me that. You said the helium field.

Q. Well, I'll ask you that now.

A. There are wells in the Oklahoma Panhandle that are closer to the Amarillo field—I mean to the Panhandle field.

Q. About what is the distance between the nearest wells between the two fields, approximately?

A. Well, those wells in the Oklahoma Panhandle would be approximately—possibly 30 miles.

Q. The nearest one is 30 miles?

A. Yes.

Q. How do you know this is not all one great field, the Hugoton field and the Panhandle field of Texas?

A. I think they are separated by a syncline in northern Moore County. There may be a very small neck in northeastern Moore County which wouldn't be over three or four miles wide, where there may be a connection.

Now, that has not been proven and I wouldn't be willing to say that that connection exists, but I think there is a possibility that it may exist.

Q. The producing formations in the Hugoton field are just about the same as the Panhandle field.

A. That is my interpretation of it.

Q. There is an enormous amount of gas in the Hugoton field, isn't there?

A. I think there is. I am not in a position to discuss the Hugoton field as an expert because I have never made a close study of it.

Q. Has there been very much drilling between the two fields?

A. There have been several test wells drilled.

Q. There has been very little drilling, then, between the two fields?

A. That is right.

Q. It is largely unexplored in that area?

A. I think that is correct.

* * * * *

Q. Now, if there is a drainage indicated by your map—if there is drainage indicated by your map—I'm not saying that there is—isn't the principal cause of that drainage those Canadian River wells which are highly productive in the

southwestern part of Hutchinson County and the southeastern part of Moore County—northwestern part of Potter County—northeastern part of Potter County?

A. That appears to be true to me.

Q. Don't you think Canadian River is getting its share of the gas in there with all of those highly productive wells?

A. They are getting some of it as it goes by.

Q. As it goes by? How fast does it go by?

A. Well, I have seen those pressure contours change from year to year as we have drawn up the pressure contour maps of the field. There is always a very noticeable change with encroachment of the low pressure areas southwestward into Moore and Potter Counties.

Q. Do you know what the production of the Canadian River wells has been in the southwestern portion of Hutchinson County?

Mr. Spencer: Total or current?

Mr. March: Total from the beginning.

The Witness: I don't have that figure.

By Mr. March:

Q. Do you know what the total production of gas in the entire Hutchinson County area has been?

A. I don't have that figure.

Q. How do you know any gas is getting by?

A. By changes from year to year in pressure contour maps.

Q. Well, with all the enormous production which the Canadian River takes out of that area, aren't they largely responsible for bringing those pressures down there themselves?

A. They contribute to the falling pressure, but I don't think they are solely responsible.

Q. If they were producing their 25 per cent there they would certainly be contributing considerably to the decrease in pressures, would they not?

Mr. Spencer: That is a hypothetical question.

Mr. March: I am asking it that way.

The Witness: If they are producing 25 per cent of their capacity?

By Mr. March:

Q. That is right.

A. They would be contributing very substantially to the fall in rock pressure.

Q. Have you made any study to ascertain just what percentage of the total decline in rock pressure they are responsible for in that area?

A. I have made such a study but I am unable to give what the results were now. I don't remember.

Q. You really can't say, can you, for certain, if any gas is going to the lower pressure areas in the northeast?

A. I think that is unquestionable.

Q. Have you any figure to sustain that?

A. No. I can give you one illustration that I think might be valuable. In the Sanford-Borger area in spite of the fact that substantial production of gas is being taken, the rock pressures of the wells that are actually producing are rising from year to year.

Q. How much are they rising?

A. It varies quite a lot.

Q. What are the pressures in there now? It seems to me they are pretty low.

A. This booklet I have here in my hand is a booklet put out by the Dwight Well Log Service showing the determinations from tests completed by the Railroad Commission of the State of Texas for the summer of 1940. I have gone through reports of previous years and marked down the lowest rock pressures of any given well in that area and the date when that lowest rock pressure occurred, and if you compare that lowest rock pressure with the present rock pressure, it is quite apparent that these wells are building up rather substantially.

J. D. Thompson, Jr., also testified with respect to testimony given some years ago in the United States District Court for the Northern District of Illinois, in the Chicago District Pipe Line Company case. Commission Counsel quoted from his testimony (Vol. 94, p. 14350) as follows:

"Q. In the figures that you have used with respect to the amount of gas originally in the field, did that or did it not refer to recoverable gas?

"A. It does cover recoverable gas.

"Q. Does it exclude gas which you do not consider re-

coverable which may be in the field? Perhaps I ought to ask you, will you explain what you mean by recoverable gas?

"The Master: Yes, I think that is proper.

"The Witness: Well, I have assumed practically 100 per cent recovery. That has been accomplished in other fields. As the gas becomes more valuable it is sometimes desirable to put gas wells on a suction or vacuum to get it all out finally.

J. D. Thompson, Jr., further testified with respect to the testimony given in the Chicago case, and above quoted (Vol. 94, pp. 14377-14380) as follows:

Q. Mr. Thompson, I almost overlooked the matter in which Mr. March interrogated you about with respect to your testimony in the Chicago District Pipe Line Company case which was held before a Master, I believe, in the Federal District Court in Chicago.

Mr. March: That's right.

By Mr. Keffer:

Q. You gave an estimate of the gas in the field as you stated this morning and also an estimate as to the life of the field and I believe that the portion you read, Mr. March, he also gave an estimate of withdrawals for 1935, 1936 and 1934, is that correct?

Mr. March: I think he has read that part.

Mr. Keffer: It is in the transcript. I just didn't want to go over that.

Mr. March: That was in there.

By Mr. Keffer:

Q. Now, that case was held—that hearing was held, as shown by this transcript, in the summer of 1934, was it not?

A. Yes.

Q. Will you state, Mr. Thompson, whether there were any unusual conditions or at least any conditions occurring in the field or present in the field at that time which are not present in the field today?

A. Yes, there were. They were stripping and blowing to air huge quantities of gas.

Q. I will ask you whether you recall that an increase of stripping operations and popping gas into the air—whether it was on the increase or decrease at that time.

A. At that time it was on the increase.

Q. Was there any indication that you know of at that time that that practice would be stopped?

A. No, I anticipated that it would continue.

Q. If that practice had continued on through the years, certainly there would have been a much larger production of gas from the Panhandle up to this time than has been the case, is that not true?

A. Yes, that's true.

Q. Now, you also stated at that hearing, as disclosed by the reading of the transcript this morning which covered a portion of your testimony, that all of the gas in the Panhandle down to zero pounds pressure would be recovered, is that correct?

A. Yes, I did.

Q. I will ask you if there were any circumstances or conditions existing in the field at that time which do not exist today that caused you to believe that gas would be produced down to zero pounds in the Panhandle gas field?

A. Yes, the stripping plants had no transportation problem at all. They merely took the gas from the well, stripped the gasoline out of it, and popped the residue into the air. They could withdraw gas down to zero pounds in my opinion.

Q. The gas which was supplied in a given stripping plant was generally collected right around close to the plant, was it not?

A. Yes, I believe that is true.

Q. Not only did they have no pressure problems as far as popping the gas into the air, but they had a very insignificant pressure problem with respect to gathering the gas, did they not?

A. That is right.

Q. Do you believe that pipe lines in the Panhandle gas field will withdraw gas down to zero pounds pressure?

A. No, I think that they will do.

* * * * *

J. D. Thompson, Jr., further testified (Vol. 94, pp. 14388-14391; 14405-14407) as follows:

Recross Examination.

By Mr. March:

Q. Now, Mr. Thompson, do you know those wells that you just recited off here in the center of Potter County in the yellow area, have declines in pressures from 1939 to 1940?

A. Yes.

Q. Have you made a study of production from those wells during that period?

A. Oh, to a certain extent I probably have but not for the purposes of submitting any testimony here.

Q. Well, now, Mr. Thompson, then you don't know whether or not they produced enough gas, then, to drain that area themselves, do you? Strike that.

Do you know whether or not the wells that you just recited here as losing pressure during that period, that this one well up here in Section 31 was losing pressure without any production—eight pounds in pressure—do you know whether or not those other wells were producing large quantities of gas?

A. I presume they were producing rather substantial amounts of gas.

Q. Have you got the production there?

A. No, I don't have the production here.

Q. You testified I believe previously that you had made no study of the production from these various pressure zones which you have here. Well, now, have you since my last examination of you made any examination of the production of those wells?

A. You are referring now to the wells in Potter County?

Q. That's right.

A. No, I haven't.

Q. Well, now, Mr. Thompson, if you have not, how can you state that the reason—or imply the reason that this one well lost pressure of eight pounds without any production was because of long distance drainage over towards the Sanford-Borger area?

A. I think you are misstating what I said a little bit.

Q. You don't mean to leave that impression?

A. I meant to say that it has lost in pressure, which was due to drainage mostly to the north and northwest. I think that is the most reasonable interpretation that you can make on it.

Q. And have you studied the production of the field during that same period immediately to the north and to the northeast?

Mr. Spencer: He says he has not, Mr. March.

The Witness: No, I haven't.

By Mr. March:

Q. All right, then, how do you know, Mr. Thompson, that that gas which moves away from this one well here in Section 37 was not because of local drainage to other Canadian River wells right in the area?

A. You say in Section 37?

Q. Section 31.

A. 31, yes. I don't know exactly to which well such drainage might have gone.

Q. As a matter of fact, Mr. Thompson, if you haven't made a detailed study of the production of the wells and the Canadian River wells surrounding this one well and the wells which you recited a few moments ago, you can't tell whether or not it was local drainage because of the movement of about eight pounds away from that well or not or whether or not it was long distance drainage, can you?

A. I don't believe I claimed that that eight pounds moved a long distance. I am sure I didn't.

Q. Well, now, if these other wells that you recited here did have very substantial production during 1939 to 1940, it is very likely that they could themselves have been responsible for pulling that eight pounds down—the pressure down eight pounds.

A. Partially responsible but not competely responsible.

Q. What makes you think it is not completely responsible?

A. Because I think you have got a general migration of gas to the north and northeast all through that country.

Q. To the north is a chain of Canadian River wells, isn't there?

A. Yes.

Q. Then you haven't made a study of the production of those Canadian River wells to find out whether they could not have taken that gas, have you?

A. No. I have answered that question about ten times that I haven't.

* * * * *

Q. You were going to find out for me, Mr. Thompson, how many wells were producing gas in Hutchinson county. Did you obtain that information?

A. I believe so. The Railroad Commission listed in 1940 a total of 303 gas wells in Hutchinson County and also 14 oil wells which were producing some gas.

Q. How many wells—strike that. How many wells in the Borger-Sanford area have been sour gas wells that have blown sweet gas, do you know?

A. What do you mean? What do you mean "have blown sweet"?

Q. That is right. How many of the sour gas wells have turned sweet?

A. I have no data on that with me here at all.

Q. Did you ever make a study of it?

A. I have made observations concerning it on several occasions.

Q. If there has been vast amounts of gas removed from Moore County and Potter County and Carson County, sweet gas areas over into the Borger-Sanford area, why isn't all of that area sweet gas now?

A. Because there hasn't been enough gas to go over there yet to change it from sour gas to sweet gas.

Mr. March: That is all.

Redirect Examination.

By Mr. Keffer:

Q. Mr. Thompson, in respect to the last question that was just asked you—I am stating the law in this respect—it takes very little hydrogen sulphide to make gas sour, does it not?

Mr. Lange: Of course the law provides for the content.

Mr. Keffer: That is right. Mr. Thompson may not know the exact content but he knows it takes very little hydrogen sulphide to classify the gas as sour.

Q. Is that right, Mr. Thompson?

A. Yes, I do know that.

Q. And the wells in the Borger-Sanford area originally had a very high content of hydrogen sulphide, didn't they?

A. That is my information.

Q. Take an area in which the pressures have gone down to 200 pounds. There would still be a lot of gas left, wouldn't there?

A. Yes.

Q. Then as sweet gas migrated into the area where there was gas of hydrogen sulphide content to mix with it, it would take a tremendous volume of sweet gas to bring the hydrogen sulphide content down to the point where it would be classified as sweet gas, wouldn't it?

A. Yes.

Testimony of C. Dox Hughes
Witness for Canadian.

Canadian offered C. Dox Hughes as a witness, who submitted a reserve estimate for the Texas Panhandle Gas Field. Mr. Hughes' testimony, with respect to his estimate, is as follows:

Qualifications

Witness was born in 1896 and is now a resident of Amarillo, Texas, having lived there since February, 1926.

His technical education was received at the University of Kansas where he completed his course in geology in June, 1920.

He accepted a position with Empire Gas and Fuel Company in the summer of 1920 at El Dorado, Kansas, where he was in charge of the Empire geological work in the Greenwood County area. This work included supervision of the drilling of wells and recommendations concerning acquisition or surrender of leases.

In 1922 he was transferred to Duncan, Oklahoma, and was made District Geologist for Southwest Oklahoma. His duties consisted of the supervision of the drilling of wells, recommendations as to lease purchases or surrender, and reconnaissance field work, and in this connection he studied the entire Permian and associated formations of western, south-

western and southern Oklahoma. Much of this reconnaissance work was done in connection with Dr. Chas. N. Gould. The witness subdivided and mapped a large area between the Wichita and Arbuckle mountains and interpreted the regional structural geology of that area. He directed considerable core drilling along the north side of the Wichita mountains and made discoveries which necessitated a complete reclassification of the Permian beds in southwestern Oklahoma. This work was of particular value with respect to the Texas Panhandle Field because of the similarity of the Wichita mountains to the sub surface conditions in the Texas Panhandle Field.

In December, 1925, he was given an assignment at Cisco, Texas, in charge of geological work for the Empire Gas and Fuel Company in that area.

In February, 1926, he was transferred to Amarillo, Texas, as District Geologist for the Empire in charge of the Texas Panhandle Field. Development in the Texas Panhandle Field was just getting under way at that time and the Empire was active in drilling wells in that area.

He resigned his position with the Empire in March, 1929, and has been an independent consulting geologist since that date with continuous residence in Amarillo, Texas. The bulk of his time has been spent on work in the Texas Panhandle Field but has also included studies of parts of New Mexico, Colorado, Kansas, Oklahoma, Louisiana, Arkansas, Missouri, Mississippi and Tennessee.

During the past several years the major portion of his work has been confined to the Texas Panhandle Field. His clients have included many of the large companies and individuals, land owners and royalty owners, gas companies, carbon black companies, gasoline plant operators and the Attorney General's office of Texas.

He has directed the purchase of considerable gas acreage based on his geological interpretations, which includes most of the acreage purchases by the Panhandle Eastern Pipe Line Company in the Texas Panhandle Field. He also supervised the drilling of most of the early wells for this company. He has purchased leases for Consolidated Gas

Utilities Corporation in Wheeler County. He has done consulting work on oil problems in this area, which included recommendations as to buying and selling of leases, royalties and wells, and also included appraisals for inheritance and income tax purposes.

During his services with the Empire Gas and Fuel Company he supervised the drilling of many oil and gas wells and observed the completion of many wells belonging to other companies and individuals. He did much work of this character also for the Panhandle Eastern and in addition to the wells with which he has had personal contact, he has kept abreast of the completions of wells since that time by means of logs, samples of formations and other records.

He recommended the purchase of a gas lease on some 60,000 acres of the Burnett ranch in Carson County, Texas, utilized by the Cities Service for a gas reserve for its Kansas City line, which was one of the first major trunk pipe lines out of the Texas Panhandle Field.

(Exhibit 211, pp. 1-7, Vol. LXIX, pp. 10043-49.)

Estimate of Gas Reserves

The methods employed by Hughes in estimating gas reserves in Texas Panhandle Field are generally described in Volume LXIX, pp. 10050-10064, and Exhibit 211, pp. 1-16.

Practically all gas wells in the Texas Panhandle Field are drilled (completed) with cabled tools. When gas is encountered it can be detected at the mouth of the well and as the drilling continues and the flow increases this can also be detected. If the producing formations were thick and soft and porous large volumes of gas would be blowing into the air, but on the other hand if the producing formations were thin and hard and tight the increase as drilling continued would be slight and upon the completion of the well a small amount of gas would be evident. After watching the completion of many of these wells the witness concluded that large wells were encountered where the combined effective producing formations were thick and soft and porous, or where there was some combination of this arrangement, and ordinarily small wells were encountered where the combined effective producing formations were thin and hard and tight, or where there was some combination of this arrangement.

There are some exceptions to this rule. A few gas wells in the field have encountered crevices or cavernous conditions where large volumes of gas were found upon merely reaching the pay formations. This is also true in some of the Granite Wash wells where the vertical permeability is extremely well developed and where large volumes of gas are obtained immediately upon encountering the pay formations. These wells are in the minority. Based upon his own observations affecting several hundred wells, the witness has concluded that large gas wells occur where the pay is thick and soft and porous and that small wells occur where the pay is thin and hard and tight. The witness stated that this was also the unanimous opinion of others who are familiar with the Texas Panhandle Field.

The original virgin reservoir pressure was the same over the entire field. Reserves of gas in place is dependent upon pressure and upon the effective pay thickness and its porosity. Although there are slight variations it can be stated that the open flow volume of a well is dependent upon thickness of pay and permeability of the pay. Vertical permeability in this field is usually low which makes it necessary, generally speaking, to penetrate the entire producing formation. Since the large open flow wells are found where the producing formations are soft and porous it follows that in the Texas Panhandle field permeability is best where the porosity is best and permeability is least where the porosity is the least. It is the witness' opinion, therefore, that for practical purposes permeability varies with porosity.

Virgin Natural Open Flow is an important index to Original Gas Content because:

Reserves are governed by

Pressure (this is the same factor affecting both Reserve and Open Flows).

Thickness (this is the same factor affecting both Reserve and Open Flows).

Porosity (for practical purposes, in the Texas Panhandle this varies with Permeability).

Open Flows are governed by

Pressure (this is the same factor affecting both Open Flows and Reserve).

Thickness (this is the same factor affecting both Open Flows and Reserve).

Permeability (for practical purposes, in the Texas Panhandle this varies with Porosity).

The witness stated that if small gas wells were discovered in the Texas Panhandle Field where the pay was soft and porous, but low in permeability, then his conclusions would not be true. He stated, however, that the small wells did not occur under these conditions but on the contrary they do occur where the pay (producing formation) is hard and tight. There are exceptions to this general rule which consists of the freak wells which encounter their entire open flow volume upon reaching the pay. These wells are usually within areas of more normal conditions as indicated by normal wells around them and can thus be appraised as freaks (exceptions), but even if treated at full value in accordance with the open flows they would not affect the answer on the whole to any very great extent since the areas they affect are small.

There is a direct relation in the Texas Panhandle Field between virgin natural open flow and original gas reserves in place. The witness made some computations in 1930 based upon the porosity-thickness method and which computations included a number of gas wells upon which he had the most reliable information. These calculations indicated that where his thickness and porosity computations indicated a reserve of 10,000,000 cubic feet per acre that the well itself had about 10,000,000 cubic feet open flow and where the thickness and porosity calculation indicated 5,000,000 cubic feet per acre the well itself had about 5,000,000 cubic feet open flow. He then concluded that it was practical to go from the known areas into the unknown by means of the open flow comparisons without making thickness and porosity determinations. The virgin natural open flow in the unknown areas served as indicators of reserve, or original gas content in place. It then became his practice to arrive at estimates of

the gas content of leases by comparing the open flows of the wells in the areas in question with those areas concerning which he had complete data.

He has used this method for the past 10 years in his consulting work for various companies, large and small, independent operators, lease buyers and sellers, royalty buyers and sellers, individual land owners and royalty owners. This method has been used in making appraisals for concerns proposing to drill wells and build pipe lines and proposing the purchase of leases and wells and royalties as well as for the selling of leases and wells and royalties, and in connection with carbon black plant operations and proposed pipe line expansions and for inheritance and income tax settlements.

In the early stages of the development of this method his studies were on portions of the field only and involved separate leases and tracts and did not involve the entire field. When he later made estimates of the reserves for the entire field the method was then applied to the field as a whole. The application was made to the field as a whole by means of a map of the field which showed the natural open flow or potential of each well under virgin or approximately virgin rock pressure conditions. The field was divided into classifications based on open flows, but in determining his classifications he used in addition to the open flows his knowledge of structural and stratigraphic geology at the well and in the various areas of the field. In some cases the boundary lines between zones or classifications of acreage took into account corrections for wells that had been drilled in at slightly reduced pressures which meant that the well would have been larger had it come in at virgin pressure. The witness has later taken this into account by actually correcting the open flows of the wells to virgin pressure conditions before placing the open flow on the map. Such corrections have been made in accordance with the United States Bureau of Mines back-pressure curves. The witness then determined the average potential or open flow for each zone shown on his map. This was done by averaging the open flows of all of the wells in each zone after having studied the distribution of the wells and after having concluded that the average was representative. The witness

stated that there would be minor variations with respect to the exact limits of each zone but that this was taken into account in arriving at his average figure as representing the open flow of each of his zones.

These zones are shown in the colors on the zone map or productivity map prepared by Hughes, Exhibit 212.

The method has been refined from time to time, the greatest refinement having come with the completion of new wells giving more complete information on the exact zoning of the field by potentials or open flows. The field has been enlarged somewhat by the acceptance of the Railroad Commission's outline of the field. This has resulted in the inclusion of some 200,000 acres which the witness considered practically worthless for gas production. This also resulted in the addition of an additional zone to the potential or productivity map (Exhibit 212) so that now the witness uses five zones, the lowest zone being from zero to 500,000 cubic feet potential.

Additional refinements have come through the application of Boyle's Law (pressure decline) at various times and in various ways. This was accomplished by applying Boyle's Law at different times to areas within the field where it was considered that the effect of drainage could be evaluated and by weighting the pressures with acreage times potential instead of weighting pressures with acreage only. This gave a better weighted pressure because potential along with acreage constituted a better index to the varying volumes of gas contained in the formations. The application of Boyle's Law (pressure decline) to various parts of the field constituted a check or test on the witness' original observations but did not result in a revision of the factor of .919211, which is the factor he is now using and has used for a number of years. The areas utilized in testing the method are located in the eastern part of the field, the central portion of the field and the western portion of the field are representative of the field as a whole.

The estimate of original gas reserves of the field by the utilization of this method and by the application of the .919211 factor to the average potentials or open flows is described briefly as follows:

The average in each zone shown on the productivity map (Exhibit 212) is determined by actual measurement from the map.

The average open flow for the wells in each zone is also determined, corrections being made as hereinafter shown where such corrections are necessary. Consideration is also given to structural conditions and other data in order to arrive at a true virgin open flow condition or relationship.

The average potential or open flow for each zone, determined as hereinabove outlined, is then multiplied by the acreage in each zone. There is then applied to this product the factor of .919211. In other words the witness takes approximately 92 per cent of the product of acreage times average potential or open flow, which results in the volume of gas at zero pounds bottom hole or absolute pressure on a 16.4 pound pressure base. The sum of these products is then added, which gives the volume of gas in place for the entire field.

The addition of these sums for each zone results in a grand total of 19,822,646,947 Mcf. as the original reserve or gas content at zero pounds bottom hole on a 16.4 pound pressure base and this figure converted to a zero pounds wellhead pressure gives 19,233,517,929 Mcf. as the original volume of gas in place at zero pounds wellhead pressure.

The witness has then applied to this figure a recovery factor of 90 per cent. (The reasons for applying a 90 per cent recovery factor are hereinafter set out.) The result of the above computations gives an estimate of recoverable gas originally in place in the formation at zero pounds wellhead of 17,310,166,137 Mcf.

The witness has tabulated his estimate on page 15, Exhibit 211, giving his estimate of original recoverable gas in place at various assumed abandonment pressures from zero pounds wellhead to 100 pounds wellhead and also shows the present recoverable reserves as of August 1, 1939.

The estimates are as follows:

"Original Recoverable Gas Reserves of the Texas Panhandle Field on 16.4 Pounds Base, and 90% Recovery Factor.

0 lbs.	17,310,166,137 Mcf.
25 lbs.	16,325,198,631 Mcf.
50 lbs.	15,302,587,914 Mcf.
75 lbs.	14,279,798,799 Mcf.
100 lbs.	13,295,009,700 Mcf.

Total production from the field was 7,485,066,520 Mcf. at 8-1-39, and subtracting this from each of the above figures the

Present Recoverable Reserves (at 8-1-39) follows:

0 lbs.	9,825,099,617 Mcf.
25 lbs.	8,840,132,111 Mcf.
50 lbs.	7,817,521,394 Mcf.
75 lbs.	6,794,732,279 Mcf.
100 lbs.	5,809,943,180 Mcf.

The above figures may be converted to a 14.65 pound base by multiplying by 1.11945."

The above estimates are based primarily upon computations made from data shown on the productivity map prepared by Hughes (Exhibit 212). The outline of the open flow zones as shown on this map have been revised from time to time where the drilling of additional wells made it necessary. Revisions have not always been made, however, where the open flow of a well drilled in a particular zone did not correspond with the classification theretofore made. This is true particularly where the deviations from the zone map tended to compensate, and made no difference therefor, in the final result of the computations.

The witness in 1939 (Vol. LXXIX, pp. 11621-11624) again tested the zone classification (productivity classification) as shown on Exhibit 212, by studying the entire field in the light of all wells drilled in the field. He did this by classifying the entire field as to virgin natural open flow on a section by section basis (640 acres being a section) rather than by zones of similar open flow as shown on the map. Sections where no wells had been drilled were classified ac-

cording to the nearest development and according to geology as far as possible. The geology took into account structural position, type of pay (formation) to be expected, whether the tract was located in an area where the pay (formation) was well developed or not, and trends in those areas where evidence of porosity conditions existed. This proved to be a satisfactory confirmation of the zone or productivity map, Exhibt 212, although the computation based on the map gave a somewhat higher reserve estimate.

Hughes further testified on cross-examination that his method of estimating reserves, based upon potentials or open flow of wells, as corrected, is not a new method, but is one that has been in use in the oil business for a long time, and although the witness does not know of anyone that has used the method directly as he has used it, he has been convinced of its soundness for several years. (Vol. LXXVIII, pp. 11496, 11497.) That the only thing he had done in this case was to apply a well-known relationship between potentials of oil wells and reserves of oil. He has applied the same basic method to the gas field apd in his opinion it should work better in a gas field than it does in an oil field. (Vol. LXXVIII, p. 11525.) The method follows the fundamentals of physics. The pressure in the formation is one of the factors which you must know in order to estimate gas reserves. Thickness of the producing formations is another thing you must know. You must also know the porosity, and by that the witness made it clear that he meant *effective* porosity, that is, inter-connected porosity in the formation. Pressure influences open flows. Permeability, of course, governs open flows and this is related to porosity because you can't have permeabilty unless you have some effective porosity. The two start from a common point. If there were no porosity there would be no permeability, and thus they end with a common point. Permeability generally increases with porosity. All of these things follow the fundamental laws of physics and they are also correlated with the witness' practical experience in the Texas Panhandle Field. (Vol. LXXVIII, pp. 11499-11501.)

In the early stages of the development of his method, as applied to the Texas Panhandle Field, the witness had determined the porosity and thickness of the producing for-

nations in different areas of the field. His determinations as to porosity were not based upon cores but were made from porous pay formations that had blown out when the wells were being drilled, which portions the witness knew were coming from the pay formations because they contained gas. (Vol. LXXVIII, pp. 11465, 11466, 11468.) Pay thicknesses were determined from wells concerning which the witness had observed the actual drilling operations. (Vol. LXXVIII, p. 11471.) These observations in connection with the actual porosity and pay thickness determinations in these areas caused the witness to conclude that there was a relationship between potentials and reserves. (Vol. LXXVIII, pp. 11476, 11477, 11478.) The witness first determined the actual gas in place and relating this to the open flow volumes of the wells, arrived at a relationship. (Vol. LXXIX, p. 11610.) The initial tests were made prior to 1930 on a group of wells on the Burnett ranch in Carson County, Texas (Vol. LXXVIII, p. 11479); also tests in Wheeler County (Vol. LXXIX, p. 11679); also other studies and observations more recently in the western portion of the field (Vol. LXXIX, p. 11680), and his most recent study shows that his conversion factor should be lower than the one he has used in his Exhibit 211 (Vol. LXXIX, p. 11680).

The reasonableness of the factor has been further checked by taking each 640-acre tract in the field and making estimates as to each such tract which gave a figure a little less than his over-all estimate in this case. (Vol. LXXVIII, pp. 11548-11550, Vol. LXXIX, pp. 11623, 11624.)

On cross-examination Hughes was challenged by Commission counsel to cite any specific proof from published scientific journals to the effect that open flow indicated gas in place. The witness then referred to investigation 3313 of the United States Bureau of Mines, being a bulletin titled "Extent and Availabilty of Natural Gas Reserves in Michigan 'Stray' Sandstone, Horizon of Central Michigan." The report was prepared by E. L. Rawlins and M. A. Schellhardt. The report reflects that they made an estimate of gas reserves in Michigan on the porosity thickness method. To do this you must have porosity and you must also have thickness. The witness then quoted from the bulletin as follows:

"Two principal methods of analysis have been used in this report to determine the average productive thickness through a field. The first method is based on an average of the interpreted productive thickness of the individual wells in the field being studied."

"The second method is based upon an interpretation of average open flow volume per foot of productive thickness * * *."

The witness stated that it is quote obvious that Rawlins and Schellhardt arrived at thicknesses in individual wells that were studied, and in some wells where the thicknesses were unknown they used the open flow as an indicator of the thickness.

The witness stated that the persons making the estimate had to have an estimate of porosity and in order to relate this to an estimate of thickness of the sand, the open flow was taken as a guide. The witness doesn't assume an average porosity to relate to his open flow, and he stated that if he desired to follow specifically what was done in Central Michigan that he could assume a porosity of 20 per cent, say, and by means of the open flow estimate pay thickness. He could then use the porosity and thickness as the basis for a computation of reserves.

The only difference between what the witness does and what Rawlins and Schellhardt did was that the witness considered open flow as a guide to both porosity and thickness, while the others had an assumed porosity and with that assumed porosity considered the open flow as a definite guide to thickness. (Vol. LXXXV, pp. 12691-12694.)

The witness then stated that he had discussed with Rawlins just what he was doing in the Texas Panhandle Field, and how he had arrived at a relationship between open flows and reserves in place. He attempted to relate the conversation he had had with Rawlins on this subject. This was objected to by counsel for the Commission and the soundness of the objection was granted by counsel for Canadian and the conversation was not related. (Vol. LXXXV, pp. 12695, 12696.)

The witness stated that Rawlins and Schellhardt recog-

nized the direct relationship between open flow and reserves in place and merely went through the mathematics of showing the pay thickness that was necessary to accommodate that given relationship. It was an assumed proposition all the way through based upon the definite recognition of the relationship between open flow and the reserves in place. Vol. LXXXV, p. 12697.)

The witness again reiterated that what he did was to arrive at thicknesses and porosities in a group of wells, from which point with an observed relationship between open flow and reserves he went directly from that to the field as a whole and applied the relationship to the field as a whole. (Vol. LXXXV, p. 12698.)

The witness observed the thickness and porosity on a group of wells that established the relationship between open flows of those wells and the reserves, and Rawlins did the same thing in Michigan. (Vol. LXXXV, p. 12700.)

Productivity Map, Exhibit 212

Exhibit 212 shows a picture of the entire Texas Panhandle Field with respect to the various zones of productivity.

The legend on the map, Exhibit 212, indicates the zone of productivity evidenced by each color. The yellow color represents those portions of the field where the open flows of the wells are above 40,000,000 cubic feet per day. The area colored green represents the areas in which the open flows of the wells range from 25,000,000 to 40,000,000 cubic feet per day. The red color represents areas where the open flows of the wells range from 10,000,000 to 20,000,000 cubic feet per day. The blue color represents areas where the open flows of the wells range from 5,000,000 to 10,000,000 cubic feet per day. The gray color represents areas where the open flows range from zero to 5,000,000 cubic feet per day. (Vol. LXIX, pp. 10067-10071.)

Hughes stated on cross-examination that the zones of productivity shown on Exhibit 212 represent the appraisal of the witness with respect to the productivity of each zone (Vol. LXXVIII, p. 11527) and in the witness' opinion the zone map is sufficiently accurate to enable him to make his computations. (Vol. LXXVIII, p. 11528.)

The map classifies the entire field approximately in accordance with the open flows that would be expected to be found by wells drilled in the different zones had they been drilled at the time the field was all virgin pressure. The initial potentials utilized in constructing the map were gathered from various sources, including all of the logs the witness has accumulated over a period of years, investigations that he has made, and reports on various wells where he has had occasion to make a more detailed check, as well as a study of scout reports and tickets and many other types of information." (Vol. LXXIX, pp. 11618-11620.)

The drilling of subsequent wells, the open flows of which do not correspond precisely with the classifications on the map, does not destroy the value of the map for the reason that those deviations have actually averaged out—for example, the zone map that was made a year ahead of the present map and which was based upon the information that the witness had collected at that time, gave a total product of acres times potential approximately the same as the present map made a year later, after approximately 100 new wells had been drilled and spotted on the map. (LXXIX, pp. 11621-11624.)

Still a year later another survey of the field was made after an additional 100 wells, approximately, had been drilled and this study was based upon a section by section appraisal (640 acres to a section) of the potentials, and resulted in approximately the same figure. The drilling of new wells changed the picture so little that the witness did not change his estimate of reserves. (LXXIX, pp. 11621-11624.)

Some of the wells came in with a lower potential than the zone map would have indicated and others came in with a higher potential but the net result was that these deviations compensated each other. (Vol. LXXIX, pp. 11621-11624.) As a matter of fact the map is subject to being revised every time a new well comes in, but on the other hand, past experience has shown that these revisions when made have been so slight that the difference in the zones as figured over the entire field, is negligible. (Vol. LXXIX, p. 11669.)

The witness' attention was called to a number of possible

discrepancies, that is, concerning wells that were not shown in the proper productivity zones. The witness answered that such small discrepancies did not result in an erroneous zoning of the field; that in many instances he could have zoned certain areas or portions of areas lower than he did zone them, so that the errors, if they might be called such, are compensating ones (Vol. LXXIX, p. 11691), and that these small differences do not change the over-all picture. (Vol. LXXIX, p. 11677.) These possible discrepancies referred to are found generally in Vol. LXXIX at pages 11635 to 11731. The witness explained that the so-called discrepancies did not as a matter of fact exist but that the zoning of his map in the particulars referred to, was based upon his judgment of structural and geological conditions and his interpretation of the size and performance of other wells in the immediate area.

This was all checked very thoroughly by a section by section appraisal of the field, which check gave a somewhat lower figure than indicated by the map, Exhibit 212 (Vol. LXXIX, pp. 11694; 11695). Many of the wells shown on the map, Exhibit 212, were not converted back to virgin open flows, since this was done only as to wells completed in the past three years, but the great majority of wells, as shown on the map, were completed at dates when the pressures were still high and therefore represented approximate virgin conditions. There were also some wells drilled at lower pressures, as witness explained in his direct testimony, for which he made due allowances in the construction of his zone map. (Vol. LXXIX, pp. 11589, 11590, 11612-11614.)

The witness also stated that he had discounted to a certain extent the alleged well potentials in a portion of the sour gas area in north Moore County (Vol. LXXIX, p. 1185) and that this was necessary because sour gas is on a proration basis and that the potential of the well was a factor in determining its allowable production. That is, an operator could produce more gas legally from a high potential (open flow) well than from a well of lower potential and that he had discounted those wells for the reason that his investigation had convinced him that it was the sensible thing to do; that the high potentials in that area developed very largely after proration became effective and not before. (Vol. LXXIX, pp. 11859; 11860.)

A casual examination of the initial completions of wells in the Texas Panhandle Field shows that the exceptionally large wells were developed after operators of gasoline plants in that area became desirous of having as high a potential figure as they could get and by any means that they could get it. Some of the potential figures are taken with everything in perfect condition, every mechanical arrangement in perfect order. That has been the history of fields under proration. It is then that the demands arrive for high potentials in order to have a larger volume of production allocated to them. This is definitely the thing that has happened in the sour gas area of the Texas Panhandle Field. (Vol. LXXX, pp. 11836, 11837.) The extremely large wells generally are reported only in that part of the field where the operators need high potentials. They acidize them and shoot them and do everything else (to increase the potentials). (Vol. LXXX, p. 11838.)

The witness on redirect examination in support of the fact that he discounted to some degree the apparent open flows of the gas area of north Moore County, particularly, submitted a list of forty wells from that area. These forty wells were listed on the zone map, Exhibit 212, as having an average open flow of 50.7 million cubic feet per day. The witness then took the potentials of those same wells, as shown on the 1939 report of the Railroad Commission, and converted each one of them back to a 430-pound virgin open flow or potential. This calculation showed that the accurate original potential of those forty wells on the average, based upon their present performance, was only 31.64 million per day. In other words, the performance of those wells was only 60 per cent of what might have been expected from the open flows as originally reported and as shown on Hughes' zone map, Exhibit 212. (Vol. LXXXV, pp. 12723-12725.)

These wells are listed in Exhibit 212-A, which exhibit was marked for identification and introduced by Commission counsel. This exhibit shows the name and location of the wells, the original potential, as reported and as shown on Hughes' map, Exhibit 212, and the potentials as reported on the 1939 Railroad Commission report, but after the same had been converted back to the original potential at 430

pounds virgin rock pressure. The color band in which these wells were spotted on Hughes' zone or productivity map, Exhibit 212, and the color band on which these wells should have been spotted in view of the later performance of the same, is shown on the exhibit.

The witness again stated on redirect examination that although attorneys for the Commission had pointed out several cases where wells were placed in a lower zone of productivity than they should have been if potentials alone had been considered, that there were also many other instances where small wells, and even dry holes, had been placed in higher zone classifications than they should have been had potentials alone been considered, and that he had not seen fit to change his classifications simply because dry holes or small wells had been drilled in areas where large wells would have been expected; that although there are variations here and there from the zone or productivity map, Exhibit 212, it does nevertheless reflect rather accurately the productivity of the various areas in the field on an average. (Vol. LXXXV, pp. 12721, 12722, 12723.)

Later gauges by the Railroad Commission are very significant on wells of this type. Frequently the original reports did not represent gauges at all. This was all taken into account. (Vol. LXXIX, p. 11832.)

The witness further stated on cross-examination that he had not changed from his 1938 zone map as compared to his 1939 zone map, which is Exhibit 212. He had found from examination that he had enough wells in the different colored zones to show the proper average. This is especially true in the sour gas portion of the field because there the average figure was reached prior to the inauguration of proration in that area. Proration has caused a great demand for potential in that area and resulted in many cases in a definitely inflated figure. (Vol. LXXX, pp. 11835, 11836.)

Determination of Recovery Factor

Hughes' testimony with respect to the use of a recovery factor is set out in Volume LXIX, pages 10063 to 10066, Exhibit 211, pages 17 to 19.

It will be noted that on each computation of original gas in place at each assumed abandonment pressure that the

witness has determined the recoverable gas by taking 90 per cent of the estimated original reserves in place in each case. This has been done because the witness is of the opinion that the total original reserves of gas computed to any given abandonment pressure will not actually be produced.

When the average wellhead pressures in the field reach any particular abandonment pressure there will still exist pressure differentials out in the formation away from the well bore. The differentials must exist if the wells are to be produced down to the abandonment pressure. The differential consists of higher pressures, in the formation away from the well bore, than the pressures at the well. It necessarily results, therefore, that when the abandonment pressure is reached at the well that the average reservoir or formation pressure is some figure higher than that.

It is not possible to determine the exact volume of gas involved but it is definite that not as much gas will be produced down to an average well abandonment pressure as the computations to that point would indicate. It is apparent, therefore, that some percentage figure less than 100 indicates the recoverable gas.

Still another reason for using a recovery factor results from the effect of water that gets into the pay formation. Experience shows that water is actually getting into the reservoir from wells that have been drilled into bottom water and although these wells were plugged back they were not always successful in shutting off the water. It is known also that upper water is getting into the reservoir in some cases where casing has failed to completely shut off the water above the gas formations. This water from whatever source contaminates areas by horizontal migration after it gets into the formation. This results in the trapping off of gas in the formations thereby rendering it unrecoverable. This also results in the salting of the formations at the well which renders a well incapable of production. Some wells have been abandoned due to this occurrence. Many wells have been abandoned due to the fact that water has flooded out the gas.

Several wells have been abandoned due to caving shales, collapsed casing, or low potentials. Most of these wells were

abandoned while general pressures in the areas in which they were located were around 100 pounds or more. Each abandonment of this type, besides leaving the area involved with a possible water contamination, actually increases the areas between the remaining wells in which pressure differentials will exist.

Still another reason for applying a recovery factor is the fact that many portions of the field contain hard, tight, lean areas which may never be drilled, and therefore, their gas content, even though small, will not be recovered completely.

Considering the effects of all of the foregoing reasons the witness has concluded that a 90% recovery factor would be a fair and reasonable figure to use.

Permeability as Related to Porosity

Witness further testified on cross-examination that the application of his method of the estimation of reserves in Texas Panhandle Field did not depend upon an absolute and direct relationship between porosity and permeability. Relationship between open flow and reserves exists whether there is a direct relationship between permeability and porosity or not, but that for practical purposes in the Texas Panhandle Field porosity varies with permeability. (Vol. LXXVIII, pp. 11517, 11518.) The relationship between porosity and permeability is only one of the factors that is involved in the relationship between open flow and reserves. (Vol. LXXVIII, p. 11516.)

Porosity and permeability determinations made by Shell Petroleum Corporation, Exhibit 218, indicate quite a definite relationship between permeability and porosity. The witness stated that these tests reflected that where the porosity was zero to 5% with an average porosity of 3.2%, the average permeability was .14, but where the porosities ranged from 5% to 10%, with an average of 7.7%, that the average permeability was 4.4. Where the porosities ranged between 10% to 15%, with an average of 12.4% the permeability was 21.7. Where the porosities ranged between 15% to 20%, with an average of 16.6%, the permeability was 55.2. Where the porosities were above 20% with an average of 23.1%, the permeability was 468.2. These tests all showed a definite

increase in permeability with the increase in porosity. (Vol. LXXVIII, pp. 11509-11511.) Witness stated that there will be a whole range of porosities and permeabilities in each individual well. A large well must have a large porosity in connection with a large permeability, otherwise the large open flow would not be a sustained open flow. The sustained large open flow must have large volumes of gas in the formation to sustain it and those large volumes of gas must have large porosity in order to accommodate it. (Vol. LXXVIII, pp. 11513, 11514.)

Conclusions as to relationship between porosity and permeability should not be based on just a few comparisons or determinations but you must study enough of them to be able to get average results and see what the average relationship is. However, a study of the Shell tests shows a surprising degree of relationship. (Vol. LXXVIII, p. 11519.) Another reason why isolated examples cannot be taken is the fact that the permeability determinations as well as the porosity determinations are made from small portions of the actual core. In some cases the exact sample taken is no larger than a man's little finger and then again the permeability tests are made from one portion and the porosity tests from another. (Vol. LXXVIII, pp. 11519, 11520.)

Open flow is dependent upon sand thickness and permeability which is tied-in definitely with porosity (Vol. LXXIX, p. 11650), but the fact remains in the Texas Panhandle Field that where wells are drilled into thick porous pays that you do not have low permeability. Small wells are found where the pays are hard and thin and tight. (Vol. LXXIX, p. 11655.)

Witness was further cross-examined with respect to authorities and tests as to the relationship between permeability and porosity. This examination referred particularly to the statements made by Muskat in his work on "Flow of Homogeneous Fluids" and certain data contained in tests made by Pennsylvania State College.

Hughes stated that he agreed with the conclusions reached by both Muskat and the engineers who collected the data contained in the Pennsylvania State College Bulletin, which conclusions were that porosity and permeability did not

necessarily vary directly. He stated that he had always been of the opinion that the relationship between the two was not a direct one but that he recognized, as do the authorities above referred to, that there is a relationship and that in some cases permeability and porosity did vary in the same manner. The witness stated that in his estimate of reserves in the Texas Panhandle Field he had made no claim that porosity and permeability varied directly, but his experience in the Texas Panhandle Field had convinced him that the relationship there between porosity and permeability was a close one and that, therefore, there was a direct relationship between open flow and reserves. The witness also called attention to the fact that the authorities above referred to, were dealing with *absolute* porosity, but that permeability is dependent upon *effective* porosity and not absolute porosity. The porous spaces must be connected in order to permit the flow of fluids through a solid. The witness also stated that the relationship between permeability and porosity would be much closer in a gas field than in an oil field because gas would flow more readily through porous spaces than a viscous fluid like oil. (Vol. LXXV, pp. 12680-12691.)

Testimony of STANLEY GILL, Witness for Canadian.

Qualifications

Witness was born in 1899 and resides in Houston, Texas, where he conducts a consulting engineering practice. He was educated as a mechanical engineer, graduating from the University of Washington in 1920 with the degree of B.S. in Chemical Engineering. After the completion of his undergraduate work he attended Columbia University for three years, completing the graduate course in engineering with the professional degree of Ch.E. early in 1923.

Following a year as Assistant in the Physics and Engineering Departments at Columbia University he was employed in February, 1924, as Industrial Fellow of the Mellon Institute of Industrial Research at Pittsburgh, Pennsylvania, and was assigned to the investigation of oil field and pipe line corrosion problems for the Gulf Production Company and the Gulf Pipe Line Company. He moved to Houston in February, 1924, and has remained there since that time.

From 1924 until the end of 1931, he was continuously engaged in engineering work for the Gulf Production Company. During this eight-year period his duties expanded from those of his original employment and during the latter part of such employment he had charge of a group of engineers engaged in research in all phases of production and pipe line operations.

In January, 1932, he opened a consulting engineering office in Houston and has carried on a consulting practice continuously since that time. His consulting work has been concerned with engineering applications in all branches of oil and gas production and transportation. Among the lines of work which have constituted the greater part of his engineering practice during recent years the following are cited:

(a) The design, construction, development and operation of instruments for geophysical exploration;

(b) Study and analysis of geological and geophysical data and recommendation as to drilling wells on the basis of such data;

(c) Assistance in and supervision of drilling operations, particularly as relating to high pressure technique and the control of mud-laden fluids;

(d) Design and testing of drilling and production equipment;

(e) Valuation of oil and gas properties, including estimation of reserves and of future earnings;

(f) Valuation of physical properties; and

(g) Design and operation of high pressure gasoline and condensate recovery and gas recycling plants.

Most of his clients are large independent oil producers, although he has done some work for major oil companies and for associated groups of royalty owners and small independent producers.

He has been familiar with the Texas Panhandle Field since 1926 or 1927. At that time his work in the field was in connection with special problems relating to oil production and transportation and particularly to corrosion of equipment.

His first detailed work in connection with gas production in the Texas Panhandle Field was in 1935, at which time he was employed as an expert witness in a case against the Railroad Commission. Since that time he has maintained close contact with developments in the Texas Panhandle Field. On a number of occasions he has been employed on matters relating to the field and he has also carried on independent studies of pressure and producing conditions in that area.

In addition to the experience which he has had in what might be considered the routine problems in the development and operation of oil and gas properties, it has been necessary in his consulting practice to devote a large portion of his time to the extraordinary problems which grow out of those operations on particular properties. This has necessitated extensive analytical studies with the aid of men of wide experience in, and practical knowledge of, the industry and the particular problem presented. An intelligent understanding of the various estimates of the gas reserves of the Texas Panhandle Field requires an analytical study of this character. (Vol. XCI, pp. 13973-13978, Exhibit 265, pp. 1-3.)

Witness further testified on cross-examination with respect to his qualifications that he was not a geologist although he had taken courses in geology in both the University of Washington and Columbia. (Vol. XCII, pp. 14062-14065.) The witness majored in chemical engineering at Columbia, which had little to do with petroleum. The witness explained, however, that he was one of the generation of chemical engineers who preceded formal education in petroleum engineering. Most of his generation of petroleum engineers were educated as chemical engineers, mining engineers, mechanical engineers, or something of that sort. Formal education in petroleum engineering emerged the latter part of the 1920's and is not yet standardized. (Vol. XCII, p. 14066.) The witness during his last year at Columbia had charge of four laboratories and quiz periods in the physics department. He handled the laboratories, conducted the regular quizzes and graded papers and later had charge of two of the large chemical engineering laboratories. He, in collaboration with an instructor, wrote a laboratory manual for the

course in advanced electro-chemistry. These were advanced courses. (Vol. XCII, p. 14068.)

Witness further stated that from the very beginning his problems were concerned with corrosion of oil well equipment and particularly with corrosion of oil well screens and wells in the Texas Gulf Coast. The solution of this problem is purely an economic one and relates to costs of recovery of oil. This being true, it became necessary in connection with the problem to make estimates of recoveries of oil, and therefore from the very start of his employment with Mellon Institute a very considerable part of his work would be classified as petroleum engineering, since it was concerned with questions of recovery. (Vol. XCII, pp. 14070, 14071.)

Counsel for the Commission then cross-examined the witness at length on his qualifications with respect to the estimation of oil and gas reserves. This cross-examination is found in Vol. XCII, on pages 14072 to 14129.) During the course of the examination the witness testified that he had made estimates of oil reserves in some 100 different fields and was cross-examined on some fifteen of them. He also stated that he had estimated gas reserves in some fifteen or twenty gas fields. He named fourteen of them and was cross-examined to some degree upon those named.

Determination of Effective Porosity, Texas Panhandle Field

Gill stated that the average porosity of 20%, assigned to the commercial acreage by Thompson, was the result of his many years experience in the Texas Panhandle Field and other gas fields. Peterson on the basis of a similar background of experience has arrived at the same conclusion as to average porosity. Thompson based his use of the 20 per cent porosity figure upon close observation of Texas Panhandle Field wells and upon correlation of the results of these observations with recoveries that had actually been had from other comparable areas.

Gill stated that the very few records of actual porosity determinations which have been made on cores of oil wells in the field indicate a considerably lower average porosity. This is usual in the case of limestone or dolomite pays from which it is seldom possible to obtain cores of the most

porous parts of the reservoir formation. In general, opinion as to over-all recovery anticipation affords a more reliable guide for reserve estimates than do the results of actual tests on cores. Even in sand reservoirs where good cores can be obtained, the core samples represent at best a microscopic sampling of the formation and are of value principally as a guide for judgment as to its character. In the most elaborate applications of core analyses for the estimation of oil reserves they apply judgment in the form of a recovery factor to arrive at final estimates that seem correct in the light of experience. In the case of limestone or dolomite reservoirs, judgment is of even greater importance.

The witness does not believe that he would himself apply an average porosity as high as 20 per cent to the limestone and dolomite pays of the Texas Panhandle Field. He has never made a careful study of the field from this point of view, but he has devoted a great deal of study to recoveries of oil out of the limestone reservoirs. Data on a group of such reservoirs are contained in Table I attached to Exhibit 265.

Table I contains a list of sixteen limestone producing fields in Texas and New Mexico showing the county in which such fields are located, the name of the field, the producing formation and the anticipated ultimate recovery of oil in barrels per acre foot.

Gill stated that anticipated recoveries out of all but two of these fields are very much less than would be expected out of formations of 20% average effective porosity. The two exceptions draw their production from highly fissured and cavernous cretaceous limestone, recovery from which is greatly facilitated by the presence of a very active water drive. With these exceptions, the oil reservoirs listed in Table I, Exhibit 265, will not yield ultimate recoveries corresponding to average effective porosities of more than 10% or 15%. It therefore appears to the witness that the 20% average effective porosity figure used by Thompson and Peterson may be too high. (Vol. XCI, pp. 14011-14013; Exhibit 265, pp. 29-30.)

The witness further testified on cross-examination that porosity determination could be made from well cuttings

and that this was done in the Turner Valley Field, for example, in Alberta Province, Canada, in which field witness had done considerable work and had estimated the gas reserves. The porosity determinations in that field were made from the well cuttings by the Canadian Government and Province of Alberta, and were utilized by witness in making an estimate of gas reserves in that field. It is impossible to make a good determination of effective porosity from such cuttings but you can make a good determination of total porosity which is higher than effective porosity. The cuttings which formed the basis for the total porosity determinations were made here from a limestone formation. The cuttings averaged a little over one quarter of an inch in length and possibly a little over an eighth of an inch in width, and possibly a twentieth of an inch in thickness, and were rotary cuttings. There were only two wells in the field in which the well formation had been totally cored and from which cores porosity determinations have been made as to effective porosity. There had also been fair-sized pieces of porous formation that had been blown out of gas wells and porosity measurements had been made on these as to the effective porosity. These pieces of formation were blown out of the holes after the completion of the well. (Vol. XCII, pp. 14108-14110.) The producing formations in the Turner Valley field are found in the Permian limestone which is similar in geological age to the limestone in the Texas Panhandle Field and is similar to such limestone in all respects. The average effective porosity of the field is about 15%. (Vol. XCII, p. 14106.)

Determination of Thickness of Gas Pays

Gill stated that the average pay thickness of 70 feet applied by Thompson to the commercial gas acreage is in his opinion a close approximation of the actual average pay thickness. This figure was reached after a careful study of records of some 500 or 600 gas wells in the field. The witness states it is rather significant and highly important in confirming the accuracy of this figure that Peterson arrived at an almost identical conclusion as to the thickness of pay, as a result of his own independent studies of about the same number of wells. Thompson's and Peterson's estimates of pay thickness differ in detail. The list of wells employed by them were far from identical. Each used wells on which

he, individually, was able to secure what he considered reliable information. On the wells which were used by both there are, in some instances, differences in interpretation. Decision as to the actual thickness of pay is in many cases largely a matter of judgment, and Thompson's and Peterson's opinions as to a considerable number of particular wells have been somewhat different. Each arrived, however, at almost identical figures for the average thickness of pay over the entire million-acre commercial area, and this fact very strongly supports the opinion of the witness that this figure closely represents the actual average pay thickness. (Vol. XCI, pp. 14013, 14014; Exhibit 265, pp. 31, 32.)

The witness testified on cross-examination that he had studied the porosity and pay thickness in the Texas Panhandle Field over a period of years—about five and a half years; that he had probably not spent more than fifteen days actually in the field, but he had spent a great deal more time than this with records and calculations in the field. He never made an actual determination of pay thickness in the Texas Panhandle Field but he has studied the method utilized in determining pay thicknesses and has done enough spot checking and examination of records and logs on his own account to satisfy himself. He has checked a considerable number of wells used by Thompson in the determination of his pay thickness, particularly the wells of Texoma, and calculated the pay thickness of a good many of them independent of Peterson, and the spot checking which he had done was sufficient to satisfy him that both Peterson and Thompson had made good estimates of pay thickness. In spot checking pay thicknesses he utilizes logs principally. He also had drilling tickets in some cases. (Vol. XCII, pp. 14140-14146.) He has spent an aggregate of five or six days in checking the thickness determinations of Peterson and has checked a number of wells he had used, being enough to see how he arrived at his figures in order that the witness might determine whether the estimates were good. (Vol. XCII, pp. 14148, 14149.) The witness also spot checked quite a few of Thompson's pay thickness determinations from Thompson's cards; which were wells that Thompson believed he had used in his determination of pay thickness. He discussed the determinations of pay thickness with both Peterson and Thompson and discussed particular wells with them. (Vol.

XCII, pp. 14174, 14175.) The witness did not take Thompson's cards and attempt to compare the pay thicknesses shown thereon against Peterson's pay thicknesses for the reason that there was no point in doing so. This would merely constitute "piddling around with picayunish detail that doesn't help in arriving at a conclusion." The fact that Thompson and Peterson differ on a particular well isn't important when their final averages come out almost identical. That shows that errors have compensated and balanced. One of the two is in error where one has more pay thickness than the other on a particular well. Maybe both are in error but the fact that the averages are substantially identical shows that those errors have compensated and it seems to the witness that this would show an open-minded man that the two of them were certainly not working together. The determination is not the pay-thickness of a particular well but their estimate of pay thickness for the entire producing area. Peterson and Thompson independently arrived at what witness considers to be a very, very sound and reasonable estimate of the average pay thickness for the Texas Panhandle Field. (Vol. XCII, pp. 14198, 14199.) The witness accepts the pay thickness, as determined by Thompson and Peterson, but stated very positively that he did not adopt either Thompson's or Peterson's thicknesses as to each individual well in specific detail, but does accept their averages as being very reasonable averages. (Vol. XCIII, pp. 14275, 14276.)

Determination of Recovery Factor

Thompson used a 90 per cent recovery factor based upon his opinion as to recoverable gas reserves. As to this factor Gill testified that there may be considerable difference of judgment. 90 per cent is a very high recovery factor for a gas reservoir, but may be justified for the Texas Panhandle Field as a whole, since trapping by water, which is a common cause of loss of recovery in many of the gas fields, will have less effect on recoveries out of the Panhandle reservoir. It is his opinion that the use of a somewhat lower recovery factor might be proper in a volumetric estimate of this type and that the use of any higher recovery factor would be entirely out of line and improper. (Vol. XCI, p. 14015; Exhibit 265, p. 32.)

Relationship of the Open Flow of Wells to Reserves in Place

Hughes employed a method in estimating reserves that is based upon an empirically established relationship between initial natural open flow, corrected to virgin pressure conditions, and per acre reserve of recoverable gas. The method and factors employed by Hughes have been devised and determined by him during some fifteen years of constant observation and study of the Texas Panhandle Field.

Gill had been familiar with Hughes' procedure for something over five years and had spent a great deal of time discussing it with him. The witness stated very positively that Hughes had developed his method by very careful and conscientious study and that he had availed himself of every possible opportunity to subject his procedure to careful and unbiased, critical, scientific scrutiny. Although Hughes' procedure originated in the Texas Panhandle Field, through his comparisons between open flows and estimates of reserves arrived at on a volumetric basis, a principle is incorporated which has long been recognized in the oil and gas industries. Experience over a long period of years and through the production of billions of barrels of oil and trillions of cubic feet of gas has shown that there is a close relationship between initial unrestricted productivity and ultimate production recoverable from a field or area. The principle is recognized in the proration orders of state regulatory bodies, which include in most of their allocation formulae a factor of potential production. It is also common practice in many areas to base valuation of oil producing properties for purposes of ad valorem taxation upon the rate of production. Prior to the application of extreme production curtailment under proration, purchase and sale of producing properties was commonly based upon rates of daily production. In all of these cases there is recognition of the general belief that a large producing well must be backed up by substantial underground reserves, and that a small well of inferior producing ability definitely indicates an area in which the underground reserves are small. (Vol. XCI, pp. 14016, 14018; Exhibit 265, pp. 34 and 35.)

The witness has on several occasions made rather detailed studies of the actual relationship between initial production and ultimate recovery in the case of oil fields. Although com-

parisons cannot be made between different fields on this basis, he has found in a number of cases that within a particular oil field the quantities of oil actually recovered from different leases and from different parts of the field was on the average quite strongly related to the initial unrestricted potentials of the wells. The witness would expect the relationship to apply more closely to gas properties than to oil properties, since the performance of a gas well reflects conditions over a considerably wider area than does the performance of an oil well. Hughes has established the fact that in the Texas Panhandle Field there is a definite, and on the average, a remarkably consistent relationship between initial open flow of wells and the per acre reserves of gas estimated by the application of volumetric methods and pressure-decline methods. Although individual wells and properties may diverge from the average, these departures are the exception rather than the rule and the agreement between Hughes' procedure and other methods of estimation is close. Hughes is currently using a multiplier of .919211 to convert from open flow to per acre reserve. This multiplier expresses the slope of a straight line curve of the average relationship between open flow and underground reserves. The application of this factor to a map zoned largely on corrected initial open flows results in Hughes' estimate of field total reserves. (Vol. XCI, pp. 14018, 14019; Exhibit 265, pp. 35, 36.)

There are two theoretical factors concerned with well performance, which may well be considered in connection with Hughes' procedure of estimation. The first of these is Hughes' use of natural open flows, corrected substantially to virgin reservoir pressure conditions. The witness feels that Hughes is entirely correct in applying these open flows rather than open flows at completion pressures or open flows after shooting or acidization. Hughes corrects completion open flows to virgin reservoir pressures by the application of back pressure curves of average slope. On the average this procedure will lead to a reasonably accurate estimate of what would have been the natural open flow of a well drilled at the particular point before pressures had been reduced by withdrawals of gas through other wells. This so-called virgin natural open flow will bear a closer relationship to reservoir conditions than will the open flow

at a partially depleted pressure or the open flow after acidizing or other treatment, which increase open flows by their effect upon permeability of formations closed to the well bore. Such increases do not truly reflect conditions in the area tributary to the well. (Vol. XCI, pp. 14019, 14020, Exhibit 265, pp. 36, 37.)

The witness further testified concerning this subject on cross-examination and stated that he had discussed with Hughes many of his calculations and the data upon which they are based and that although he is not at all certain that Hughes is absolutely correct in everything that he has done, he has arrived at a reasonably consistent method which is pretty well sustained. He has checked it by applying pressure-decline to limited areas that are in his opinion relatively free from influence of drainage and in some cases to subdivisions of areas, and in applying the pressure-decline test he weighted area and per acre content. This does not mean that he had his answer before he started. It is merely a method of checking the procedure and it is a very simple engineering procedure to check the validity of an answer of that kind. It is simply that you work the same thing two ways and come out with about the same answer. It serves as a double check on the procedure; for example, you can take the pressure-decline and figure back to a per-acre content.

You can also take the factor which Hughes used and calculate over from his zoning and the open flows of the wells in the zone to an acre content. If the two came out just about the same it would mean that the two were giving results that were in reasonable conformity. If one method consistently gave results that were higher than the other that would lead to a revision of the constant or multiplier (factor). Hughes arrived at the per acre content by the application of his factor against his open flow zone. He could then have applied, and in some cases did apply, the pressure-decline method in the limited area with which he was dealing, and weighted out the pressure-decline on that area and the per acre content and arrived at such weighted pressure-decline for the area. He started with a per acre content and he weighted the pressure-decline per acre to arrive at a weighted pressure-decline. Then in many cases he took the per acre content which he calculated by the

application of a factor, and combined these two and reached a figure for the total reserve of the area with which he was dealing. He could then apply against that estimated reserve at the beginning of his period the amount of production that had come out of the area during the period for which the pressure-decline was determined, and from that could have calculated from the production and the original reserve what the pressure-decline should have been. He would then have arrived at two independent figures for the same pressure-decline. One of them resulted from taking the surface pressures and weighting by area and per acre content, and the second, by relating his estimated original reserve to the withdrawals to reach a pressure-decline. If his estimate of per acre content was correct those two methods would give exactly the same figure for pressure-decline. If they wound up with different answers that would mean that his factor was probably wrong. If, over a series of such checks, there was a consistent trend shown, that is, if it showed that his estimates of per acre reserves were consistently high—consistently too high—to make those calculations come out even, then it would be time to revise the factor. The witness has seen his calculations on these various areas and has gone over a considerable part of the data. The witness believes that an independent application could be made of the pressure-decline method and, if made on the same area from the same data, and made honestly and competently, it would check with Hughes' estimate of reserves. The true weighted average pressure could be determined approximately by weighting pressures on surface area alone where applied to a zone, as Hughes did, where the per acre content was substantially equal throughout the zone. There are only two sets of conditions under which a pressure average on surface acreage alone can truly represent actual average pressures, that being when the pressure is equal in all parts of the reservoir or when each and every acre in the reservoir is underlaid by exactly the same volume of gas bearing voids. Mr. Hughes approached that second condition when he limited his calculation to an area in which, in his opinion, the reserve under one acre was about the same as the reserve under every other acre. Therefore, he weighted the pressures within that particular zone on surface acreage alone and got approximately an average weighted pressure on volume for that zone. He then took the next zone and

treated that separately. He didn't try to combine the two. This will serve as a sufficient check upon the field as a whole if applied to enough areas. Hughes extended that check pretty well over the whole field. The witness has gone over Hughes' work and believes that his zoning of the field is within reasonable limits of accuracy. (Vol. XCII, pp. 14183-14187, 14189-14191, 14193-14196.)

Witness explained that when he said that Hughes' zoning of the field was within reasonable limits of accuracy he had in mind that there was some error inherent in such studies. The more thorough the studies and the more thorough the data, the less the error becomes, and as time goes on the estimates get better and better and more accurate. Hughes' estimates of reserves of the Texas Panhandle Field have varied perhaps ten per cent as his data and checking and weighting of the thing lead his opinion to be improved upon and to be grounded upon sounder and sounder results. That is a common engineering practice where the accuracy of results is limited by the extent of the data available. Hughes' estimates have been developed over a period of years by continuous study testing and weighing and improvement to arrive at his best opinion as to the reserves. It is the witness' opinion that his estimate of reserves is pretty close to the actual facts. (Vol. XCII, p. 14196.)

The witness further testified on cross-examination that all of the wells shown on Exhibit 212 were not corrected back to virgin open flow conditions but the ones where the corrections amount to a substantial amount have been corrected back. Many of the wells were completed close to virgin pressure and the correction was so small in those wells that it wasn't necessary to make the correction. The witness knows this to be a fact because he contoured a couple of maps of the Texas Panhandle Field based upon corrected virgin open flows and is familiar with those figures. The witness checked Hughes' zoning of the field as detailed on map sent him in 1938 or 1939. The map he checked was not colored but it did have potentials noted on it. He checked those potentials against the Railroad Commission's open flow potentials as of that date, which he corrected back to virgin open flow in order to determine if they were in reasonable correspondence. No corrections were made in the high pressure areas because the figures used by Hughes

were close to the open flow figures of the Railroad Commission's report and therefore they were considered to be about right. The witness stated that he knew all the open flows recorded on the map, Exhibit 212, were not initial open flows at virgin pressure but that there are a sufficient number of them to support an estimate of reserves. Some of the open flows on the map don't mean anything, particularly because many of them are incorrect open flows that have been reported on the initial completion of wells and where the initial reports were erroneous these wells were not used in determining the averages. (Vol. XCII, pp. 14200-14204.)

Hughes' method will work whether he has the initial virgin open flow of every well or not. It would work just as well on most any type of uniform correction of open flows in order to make the open flow figures which he used for different parts of the field comparable with each other. The principle would apply just the same. His factor is based upon the study of factual relationships upon the field and is determined by that. (Vol. XCII, pp. 14205, 14206.)

It is the opinion of witness that it does not necessarily follow that a 10 million foot open flow represents approximately 10 million cubic feet of gas per day in place, but that he does think that this ratio is approximately correct in the Texas Panhandle Field. The witness bases this conclusion upon studies he has made which have led him to believe that the relationship stated by Hughes is approximately correct. The witness has made a good many studies of this in the Texas Panhandle Field and has made a good many studies of the work that Hughes has done and he has studied the work of other people. This conclusion is not based solely upon what Hughes did but, as stated, the witness has made a number of studies and has made independent personal estimates of the total reserves of the Texas Panhandle Field from which he learned a great deal. He has examined specific data on a large number of wells in the field. He is familiar with the performance of gas reservoirs in general, including the Texas Panhandle Field, and he bases his opinion not on any one part of his various studies, but on the whole. (Vol. XCII, pp. 14206-14208.)

The witness and those working under him spent at least a thousand man-hours of work on checking Hughes' zone

map in early 1939 (the predecessor of the present map). They calculated back and checked every one of the open flows shown on the map. That is, corrections were made in open flows where the well was brought in at a pressure so low that the correction was of importance. The witness and the men working under him took one of the maps and checked the potentials all the way through and contoured the map on virgin open flow potentials and made many calculations from them. They found the potentials on the map to be quite reasonably accurate when compared against the Railroad Commission's records. The map was checked against the latest report of open flows from the Railroad Commission, well by well. (Vol. XCII, pp. 14220-14223.)

The map that the witness checked was the one submitted by Hughes in the Texoma case and every well on the map was checked and the data were found to be reasonably accurate. (Vol. XCII, p. 14224.) (Hughes has heretofore testified that the map, Exhibit 212, is the same map that was submitted in the Texoma case, Vol. LXXVIII, page 11491).

Permeability as Related to Porosity

Gill testified on direct examination that the theoretical considerations bearing on the propriety of using open flow as a measure of reserves in place are rather complicated. In the simplest sense they are compared with relationships between permeability and porosity. Technically porosity and permeability are more or less inter-related but are not mathematically determined as to value by this relationship. The theoretical relationship between porosity and permeability is rather qualitative in nature, and may be expressed by the statement that permeability cannot exist at all in the absence of porosity, and that effective porosity, which may be loosely defined as that porosity from which fluids can be withdrawn into wells, cannot exist at all in the absence of permeability, since permeable interconnection is necessary in order to make the porosity effective. As a practical fact the relationship between porosity and permeability is much closer than this generalized statement might indicate. Within a particular pay formation it has been found, in many cases, that there is a rather direct relationship between permeability and porosity. This statement applies to aver-

ages, and many individual specimens will show relationships that vary either way from the average. In general, however, it is true that within a particular field a definite relationship between permeability and porosity frequently exists. (Vol. XCI, pp. 14020, 14021; Exhibit 265, pp. 37, 38.)

Permeability is not by any means the only factor which determines the open flow of a gas well. Although high permeability in the part of the formations immediately surrounding a well bore is necessary for a well of large open flow, there are conditions under which such high local permeability may not result in a large well. For example, the well bore might encounter a small local area in which the reservoir rock was extensively fissured or contained very large, continuous pores. If this were only a local condition, and if the large fissures or pores were fed by a formation of extremely low porosity, the well would not be able to sustain a high rate of open flow, since gas could not be fed rapidly enough to the local spot of high permeability. A high, sustained rate of flow for a gas well is possible only when the formation tributary to the well contains a large volume of gas. The volumetric content of the reservoir formation, which is one of the controlling factors in open flow, is dependent upon the thickness and porosity of the porous formation. (Vol. XCI, pp. 14021, 14022; Exhibit 265, pp. 38, 39.)

. . . . . .

STANLEY GILL also testified on cross examination (Vol. 92, pp. 14140-14146; 14179-14181) as follows:

Q. Have you ever made an estimate of reserves of the Texas Panhandle field?

A. I have made a good many of them.

Q. Where are some of them? Have you ever put them in evidence in a case?

A. No, sir.

Q. Have you ever made them for a company and furnished the company with a copy of it?

A. I have furnished Texoma with the results of a good many of them. What I have attempted to do is to make a proper application of pressure decline methods for the Texas Panhandle field by various methods of weighting and by various methods of calculation, and each time I have made such an estimate I have weighed that estimate as impartially as I have tried to weigh the estimates that have

come into this case and have decided that they were not good.

Those estimates have ranged from 22 trillion to 34 trillion, depending upon the methods that were used. None of them have stood up under my own analysis where I would be willing to accept them as correct estimates.

You understand, Mr. March, the treatment and analysis of these declines that I have applied to the estimates of Mr. Hammer and Mr. Stevens aren't something that I have invented for this case. I have been using it against my own estimates for many years.

Q. Well, you can't—you never had—

A. They are my own estimates and if my own estimates fail to stand those tests I discard them.

Q. You have never testified in a case in which you have made an estimate of the reserves of the Panhandle field of Texas?

A. Of course not, because I have never made an estimation that stood up, when I tested it impartially, and I have never made an estimate that I considered myself was a truly correct estimate.

Q. Why didn't you try the porosity thickness method?

A. I considered that the use of the porosity thickness method which had been made by Mr. Thompson and Mr. Peterson was far better than any application I could have made of it because of their far greater experience and knowledge of the field. I, therefore, did not waste time on trying to make a porosity thickness estimate which would have been in my opinion inferior in quality to the ones that they had made.

Q. Well, if you have never made a study of the application of the porosity thickness method in the Panhandle field of Texas of your own, how do you know that theirs is right?

A. I didn't say I had never made a study of that method in the Texas Panhandle field, Mr. March. I have, and I have over a period of years.

Q. How many years?

A. Well, it's a little arithmetic—about five and a half years.

Q. How much time have you spent in the Texas Panhandle field during the last five and a half years?

A. I don't suppose during the last five and a half years, I don't suppose actually, physically, I have spent over fifteen days in the Texas Panhandle field. I have spent a darn-sight more time than that with records and calculations on the field.

Q. Furnished to you by Mr. Thompson and Mr. Peterson and Mr. Hughes?

A. Some of the information.

Q. Did you have it furnished by anyone else?

A. Yes.

Q. Who?

A. Well, I had a considerable amount of data from Phillips Petroleum Company.

Q. What sort of data?

A. Well logs, principally.

Q. Have you got those?

A. I had pressure tests; I had a mass of information from the Railroad Commission of Texas.

Q. Did you ever make an examination of the pay thickness and the porosity of the Texas Panhandle field?

A. As I told you, I have studied that method and I have done enough spot checking and examination of records which —both on my own hook—of logs and more particularly with Mr. Peterson and Mr. Thompson so that I am personally satisfied to accept their estimate of thickness.

Well, that's what I have done from my own studies of this method.

Q. Did you ever try to make an estimate of thickness of the Panhandle field of Texas yourself?

A. Mr. March, I don't like to have to tell you the same things over and over. I have spot checked their methods but I have never myself made an estimate of average pay thickness over the entire Texas Panhandle field.

Q. Have you ever spotted the wells that Mr. Peterson uses on a map of the Panhandle field of Texas?

A. No, I never have.

Q. Do you know how many wells Mr. Peterson uses?

A. Something over 600.

Q. Have you ever made an examination of any of those wells to check them?

A. Of a considerable number, as I said.

Q. Which ones have you checked?

A. I don't remember, Mr. March.

Q. Can you name one that you have checked?

A. Well, I have checked with Mr. Peterson practically every one of the Texoma wells. I would say every one of the Texoma wells that were drilled prior to 1936 and most of them that were drilled from 1936 to 1939.

Q. Did you check the pay thickness calculations?

A. Now, if you want me to, I'll read the names of those wells.

Q. That is a list of all the Texoma wells?

A. That's right.

Q. Well, there is no need to read the list. You have designated them sufficiently clear, but I will ask you this:

Did you, independent of Mr. Peterson, calculate the pay thickness for those wells of Texoma?

A. A good many of them.

Q. Well, how many of them?

A. I don't know.

Q. Which wells did you calculate the pay thickness for that Mr. Peterson used?

A. I told you, Mr. March. I thought I made it clear that I had done enough spot checking to satisfy myself that both Mr. Peterson and Mr. Thompson, independently, had made what I considered good estimates of pay thickness. Now, I have used that pay thickness only a very general way. I think the pressure decline method is a much better method of estimating reserves than pay thickness when it is properly done.

Q. Of the Texas Panhandle field?

A. Any field, and of course it is terribly bad when it is improperly done.

* * * * *

Q. You testified in the Texoma case in your examination, I believe, by Examiner Simpson, on Page 1512 and 1513:

"By Mr. Morgan:

"Q. Can that method of computing reserves be applied to the Texas Panhandle field, Mr. Gill?

"A. I think it is possible to apply it by weighting to a per acre content of the field, which is essentially what Mr. Hughes did in arriving at his constant. That is, he weighted his pressures both to area and to per acre content in order

to arrive at an average pressure. I think you get a fair approximation that way."

You were speaking there of the pressure decline method as applied by Mr. Hughes. There your testimony is. Is that correct?

A. I presume so.

Q. Well, now, what pressure decline method of Mr. Hughes were you talking about?

A. It is stated exactly there.

Q. I see. Well, how did he apply it there?

A. It is just stated in what you just read, Mr. March. This is from Page 1513 where you were reading:

"That is, he weighted his pressures both to area and to per acre content in order to arrive at an average pressure. I think you get a fair approximation that way."

Now, that explains just exactly; that is, by combining both as to area and as to per acre content he did get a weighting on volume, a sort of weighting on volume, a fair approximation, as I have called it there. He did get a fair approximation of a weighting to volume of gas.

Mr. Gill further testified (Vol. 93, pp. 14254-14257; 14259-14263; 14267-14268; 14270-14272) as follows:

By Mr. March:

Q. I will refer you to Page 42 of your written statement, Exhibit No. 256—265, where you state:

"Not only do such withdrawals bring about extensive drainage, but they are of importance in controlling future trends of withdrawals. For example, heavy withdrawals of gas from Wheeler County may be expected to lead to premature reduction of pressure, and to a shift of withdrawals into the sweet gas area of Moore County."

Now, I want to know what study you have made to ascertain whether or not there will be a shift of the operations of the companies producing in the east field to the west field.

A. Oh, that isn't based on a detailed study. It is just a matter of common sense and common knowledge. It is an inevitable thing.

Q. How do you know they won't go to some other field?

A. Well, it's just that that is the most reasonable expectation. There is no—there will be a rather strong incentive to stay in the Panhandle because of the fact that to a considerable extent the trunk line and gathering line investments have already been made and as long as there is gas in the Panhandle it will to a considerable extent be more economical for those people who are now getting their supplies out of the east field to remain in the Panhandle than it would be for them to jump off into some other field which might require considerable additional trunk line investment.

Q. Isn't it quite probable that some of them will go out to the Hugoton field?

A. I don't know about the Hugoton field specifically but I think it is quite probable that some of them will get some of their supply from other fields when the east field won't supply them any further, but on the other hand I think it is absolutely certain that part of the demand now satisfied out of the east field will be taken up out of the west field when the east field production peters out.

Q. Don't you know that some of these companies producing gas out of the east field at the present time have large holding in the Hugoton field immediately north of the Panhandle field?

A. I understand that they do, and it is also true that some of the companies in the east field could reach up into the west field far less expensively than going to Hugoton.

Q. Well, isn't the acreage pretty well taken up already in the west field?

A. Generally speaking, yes, sir, but there is acreage which is not now connected.

Q. I thought it was your general opinion the whole field would be pretty well depleted at the same time.

A. Did you?

Q. Yes. Is it?

A. I wouldn't know—I wouldn't say that that question expresses my opinion at all. I wouldn't say so, no sir.

Q. You think that there will be certain parts of the field depleted before other parts of the field are?

A. Certain parts will be depleted for particular purposes long before other parts are; that is, I believe, for example, that the east field will be depleted as far as it being a source

of supply for trunk pipe line purposes considerably before the extreme high pressure area of the west field there.

Q. If there is a free movement of gas and drainage into the Panhandle field, why wouldn't the gas drain from the west field into the east field and maintain the pressure in the east field?

A. Mr. March, you asked me about that yesterday and I told you there was no effective sub-surface drainage between the east field and the west field.

Q. Do you think as a practical matter there will be?

A. As a practical matter, I don't think there will be a drainage between the east field and the west field.

Q. What is the estimate of reserves as a whole?

A. For the reasons stated on Page 42 and the excerpt you read from Page 65, that is, that depletion of the east field will result in a shift of withdrawals into the west field, and that, therefore, the reserves in the east field will have a bearing upon the eventual depletion of the entire Texas Panhandle field.

Q. When do you think this shift will take place?

A. I don't know. I haven't figured it out. It won't be so long until there will be some shift.

Q. Do you know how near the east field is to the depletion?

A. No, sir, I haven't made a reserve estimate of it. The pressures are coming down over the entire east field.

Q. Do you know in the east field there are pressures still over 400 pounds?

A. Yes, in two places in very lowly productive areas, areas of low productivity of no commercial importance as far as I know.

• • • • •

Q. Now, beginning on Page 7 and extending through Page 40 of your exhibit, as I understand that is where you start your criticism of Mr. Hammer and Mr. Stevens.

A. My discussion of their estimates, yes, sir.

Q. Now, let's first hurriedly run through here beginning on Page 7. When you weight the surface don't you have to take volume into consideration automatically?

A. No, sir.

Q. Isn't there a relation between surface and volume?

A. As I told you yesterday, surface is one of the factors

in determining volume. It is exactly the proposition if you would say that the volume of a carpet covering the floor of this room was the same as the entire volume of the room. Obviously, it isn't anything of the sort, but that is what you do in weighting pressures in a reservoir when you weight it on surface acreage alone. You say that the volume of the carpet covering the entire floor of this room is exactly the same as the volume of the entire room. That is why it is wrong.

Q. You say here: "Mr. Hammer's pressure decline method in which withdrawals of gas are compared to declines of pressure, the latter being weighted only on surface acreage, is entirely incorrect for estimation of reserves of gas in the Texas Panhandle field."

All right, now, Mr. Gill, how much incorrect is Mr. Hammer?

A. Well, it is my opinion that his estimate of total original reserves is something over 50 per cent high.

Q. How much?

A. Something over 50 per cent high.

Q. How do you know? You haven't made an estimate.

A. I have made many estimates of reserves of the Texas Panhandle field,

Q. You stated they were all wrong?

A. Yes, sir

Q. All right, then—

A. I made estimates as wrong as Mr. Hammer's.

Q. Have you ever made an estimate you thought was right?

A. No, sir.

Q. How can you measure anyone else's estimates? What do you have to go by? What standard do you have to go by?

A. I testified yesterday, Mr. Mareh, at rather exhaustive length that I have made many estimates of the Texas Panhandle field; that I had weighted them generally as correctly as I had weighted the estimate of reserves discussed in Exhibit 265, and that in every case where I had made an estimate of reserves by any one of the various applications of pressure decline procedures they had failed in the light of analysis on the basis of what is happening in the field to prove up to be correct. In other words, they failed under

analysis just as Mr. Hammer's estimate failed under analysis and for similar reasons.

Now, in the case of some of those estimates they didn't miss the material as badly as Mr. Hammer's estimate does, and—

Q. How do you know he missed it at all?

Mr. Keffer: Let the witness finish.

Mr. March: I beg your pardon.

The Witness: And in others cases they missed it as badly as Mr. Hammer did. As I told you yesterday, the estimates I have made have resulted in estimates of original reserves from 22 trillion up to 34 trillion, I believe, and in general the lowest estimate, say from 22 trillion to 25 or 26 trillion, comes closer to checking out than the higher estimates.

I have explained it at a great deal of length in this discussion, which is incorporated in Exhibit 265, that in view of the fact I have not yet been able to work out the proper application of pressure decline to the field, I am of the opinion now that the best estimate of reserves that are available on the Texas Panhandle field are estimates Mr. Hughes and Mr. Thompson have introduced here. I don't accept their estimates as absolutely correct, but I think they are the best estimates there are. My own work leads me to the opinion that the lowest estimates I arrived at which were on the order of 22 trillion for original reserves, were too high, and, therefore, I believe in my own work that the true figure is below 22 trillion; and as I say, I now am of the opinion at the present time that the figures which have been presented by Mr. Thompson and Mr. Hughes and which lead to figures less than 20 trillion, are of the best available

Q. Are they within 20 per cent of correctness?
A. Oh, yes, they are probably closer than that.
Q. How much closer than that?
A. I don't know.
Q. You don't know?
A. No, sir.

* * * * *

Q. It is your position that Mr. Hammer has not con-

tended that it would be possible for the Canadian River to recover these reserves?

A. I have made no such statement, Mr. March.

Q. You don't purport to make any such statement?

A. I haven't said that Mr. Hammer doesn't have the idea it wouldn't be physically possible for Canadian River to recover the quantity of gas under their properties. I think it could be said that it would be physically possible for them to do it but to attempt to apply that to a practical situation is sophistry of the wildest sort.

Q. Have you made a study to ascertain how much they couldn't recover?

A. I have made a rather thorough study of the probable drainage. I have not attempted to express it in quantitative terms—

Q. Can you at the present time in—

A. Let me complete my answer. I was going to state on the end of that answer that it was because I can't estimate it quantitatively.

Q. It is impossible for you to say just exactly how much of the remaining reserves under Canadian River's acreage that Canadian River will recover or not recover?

A. I think that is a correct statement.

Q. It is impossible for anybody else to say that?

A. Yes, sir, I believe so.

Q. Then you don't know if you can't measure quantitatively or cannot give any approximation of it quantitatively whether or not they could recover all of the remaining reserves under this acreage?

A. If we wished to indulge in pure sophistry I would say that Canadian River Gas Company could recover all of its recoverable gas now under its property. I don't know what in the world they would do with it, though. It would be necessary for them to move in and drill a lot of wells and blow a tremendous quantity of gas to the air or else put it up in cans and save it for future use.

As a practical matter, Canadian River will not recover anywhere near all of the quantity of gas that is now existing under that property. I know that, Mr. March, in exactly the same way that I know a louse is smaller than an elephant. However, I have never measured either one of them.

Q. It would do you good to measure them, wouldn't it?
A. No.
Q. You can measure the difference between a louse and an elephant, can't you.
A. I know a louse is smaller than an elephant.
Q. Can't you measure the difference?
A. Yes.

• • • • •

Q. Do you think when Mr. Hammer takes his quadrants and weighs in the surrounding quadrants and considers the *surrounging* quadrants in figuring each one of the quadrants he takes in to any effect his drainage which might take place in regard thereto?

A. Not to any practical extent. Now, that procedure which is a very poor and indefensible procedure, does have a tendency to take a quadrant from which gas has been drained and to indicate that the present reserve of that quadrant is greater than it actually is. To that extent it tends to erase, disguise and conceal the fact that drainage is taking place.

Q. I believe you admit here it is proper to divide the field up into quadrants in making estimates of reserves?
A. As a matter of convenience, yes, sir.
Q. It is a matter of convenience to divide the area up that way? You say, as I understand, those quadrants should follow zones of equal productivity?
A. I didn't say that.
Q. What did you say in regard to that?
A. I said they didn't follow zones of equal productivity or zones of anything else.
Q. You said they should if they were to be used at all, didn't you?
A. I don't believe so. He could have gained some information by having them do that, but I didn't say they should have.
Q. You said that Mr. Hammer's quadrants are not laid out in relation to pressure patterns, relative reserves or areal distribution of withdrawals.
A. What page is that on?
Q. That's on Page— and then you say—

Mr. Spencer: What page, please?

Mr. March: That's on Page 16.

Q. You say: "Up to the point of his determination of withdrawals and weighted pressures by 'quadrants,' Mr. Hammer has made legitimate use of his subdivision of the field area."

Now, did you imply there that when you do divide the field up into quadrants in estimating reserves that you should follow the pressure band—I mean the productivity bands?

A. No, sir, I didn't say that they should. That's what that statement means. He could have gained some information out of his subdivision by some such method of dividing, but he did not do it. I didn't state that he should have done it, Mr. March.

Q. Do you know what would have been the difference in Mr. Hammer's results if he hadn't weighed the surrounding quadrants in determining a given quadrant?

A. As to which one of the results?

Q. Any of his results—his results on the field as a whole.

A. I haven't calculated through, Mr. March, but I rather expect that his results for the field as a whole would have come out pretty close to what he got. That's just due to the accident of distribution as between his quadrants. It would be my idea that he would come out somewhere reasonably close to the same answer for the field as a whole.

Q. Why are you criticising his using the surrounding quadrants?

A. Because it is an entirely incorrect method.

Q. If he comes out with almost the same answer, why do you say the answer—why do you say it is an incorrect method?

A. As I said, I haven't figured it out—figured it through, but due to the accident of distribution it would probably come out to about the same answer but you see in arriving at the same incorrect result by two methods doesn't make it right.

* * * * *

Stanley Gill further testified (Vol. 99, pp. 15298-15300; 15347-15351) as follows:

Q. Now, Mr. Gill, if that area was formerly below 400

pounds and suddenly it became 400 pounds and over, what would you say was the cause of that?

A. I would say that if it did take place there would be some replenishment by drainage.

Q. Don't you think, Mr. Gill, there was drainage into the Canadian River acreage and repressuring here which caused the low pressure area to be wiped out of the middle of Potter County in 1937 and the 400-pound band even extended over into Moore County?

A. I really don't know, Mr. March. It is entirely possible that that particular part of Canadian River's acreage did pick up some gas out of other parts of Canadian River acreage. You see, geographically, that big high pressure area in Potter County from which much drainage would come in there is Canadian River acreage.

Q. Well, obviously, if any great movement of gas came about that way, there would be some low pressure created in a corresponding period of time in Canadian River acreage, wouldn't there?

A. I expect the pressure out in the yellow area was reduced somewhat.

Q. You notice here in 1937 there wasn't any low pressure areas created to the southwest of the repressuring area.

A. There isn't any pressure below 400 pounds shown on the 1937 map, no, sir.

Q. Now, Mr. Gill, have you made a study of that area in there to ascertain specifically the cause of that?

A. The study I have made, Mr. March, is to determine physically the cause of the overall sequence of development of low pressure back into that Moore and Potter County area. Very definitely that general overall development, although it is masked in spots by such local effects as you mentioned, is occasioned by the large regional drainage of gas out of that area into the area of very heavy withdrawals which lie in general in southwestern Hutchinson County.

Q. My question to you is specifically this: Have you made a study specifically of the production by wells to ascertain the cause of that repressuring in Potter County in 1937 and in a part of Moore County?

A. I have answered that question several times, Mr. March.

Q. What is your answer?

A. The only specific study by wells in relation to drainage trends that I have made is one, the results of which are tabulated on Page 10, Exhibit 266. That shows very positively that area to which you are referring has suffered rather extensive drainage.

I have also included in Exhibit No. 266 some calculations that I have made from Mr. Hammer's data as to his quadrants which show the same thing, and—

Q. I know. That is in the record. There wouldn't be any drainage indicated from this area in 1937 when the area was repressuring, would there?

A. There is extensive drainage out of Potter County and southern Moore County indicated by the sequence of development of low pressures in that area which is shown by this series of maps, Exhibit 239, from year to year. It is a progressive thing and—

• • • • •

By Mr. Gibson:

Q. Mr. Gill, have you by your Exhibit 265 made or attempted to make an estimate of recoverable reserves of the Texas Panhandle field?

A. That particular exhibit does not include an estimate of reserves made by me; no, sir.

Q. The same is true with respect to the Canadian River Gas Company's properties in that field?

A. That is right, yes, sir.

Q. In preparing this exhibit I notice under the heading "Scope of Study," you have stated: "I have been requested to prepare and to submit a report covering my opinions and conclusions as to the several estimates of gas reserves in the Texas Panhandle field, which have been presented in this proceeding. In compliance with this request I have studied the exhibits and testimony relating to the estimates of reserves listed below:"

Then you list the estimates, some ten of them.

A. There are four estimates of reserves.

Q. Four estimates of reserves?

A. Yes.

Q. On Page 5 under the heading "Introduction," you

make the statement: "Attention has been given to the correctness of methods employed, to the manner in which they have been applied and to the applicability of the results in determining the future producing life of gas reserves in the Texas Panhandle field."

On the same page you state: "While it must be understood that estimation of reserves of gas or oil is far from being an exact science, it must also be emphasized that reasonably accurate estimates can be arrived at by the application of proper methods."

On Page 6, in speaking of the estimation of reserves you state: "The results are 'estimates' rather than 'determinations' of the reserves of oil or gas."

On Page 7, in dicussing the estimate of Mr. Hammer, you make the statement: "Mr. Hammer has made his estimate of reserves of gas in the Texas Panhandle field by a pressure decline method which involves several unique features. I feel that Mr. Hammer's estimates are neither correct nor applicable for evaluating the probable future life of the Canadian River or field reserves. This opinion is based upon three lines of reasoning:"

I desire to ask you in this connection if it is not a fact that by this exhibit, that the only thing you have done or attempted to do is this: Instead of taking the data shown in the exhibit of Mr. Hammer and using it for the purpose of making an independent estimate of recoverable gas reserves of the Canadian River's properties, you have taken that exhibit and given it a critical study for the sole and only purpose of arriving at your conclusions and stating your opinion with respect to the correctness or incorrectness of the inference made, the conclusions deduced, and the opinions stated by Mr. Hammer in the making of his estimate?

A. That question is involved, Mr. Gibson, but I will refer you back to the quotation which you read from Page 4 as to the scope of the study. I have done exactly what I stated there; that is, I have prepared and submitted a report covering my opinion of conclusions as to the overall estimates of gas reserves in the Texas Panhandle field

which have been presented in this proceeding. That is what I have done.

Q. An estimate constitutes nothing more or less than a formulation of opinion based upon data, opinions, theories, and judgments; isn't that a fact?

A. Yes, sir, I would say that is correct.

Q. Then it is true that the only thing you have done is to take the data, the observations, the theories, the judgments, the inferences, conclusions, and opinions stated by Mr. Hammer and the others in these exhibits and after having made a study of the same you have arrived at your conclusions and formulated and stated your opinion respecting the correctness or incorrectness of the inferences, conclusions, or opinions stated by them?

A. I have expressed my opinion as to the correctness of their results and have detailed my reasons for arriving at those opinions. That is what I have done.

Q. That is all you have done or pretended to do, is it not?

A. I have done what I stated here in this report that I intended to do, yes, sir.

Q. What is said with respect to Mr. Hammer applies likewise to all you have mentioned in your exhibit?

A. I have studied the estimates and arrived at the conclusions stated in my Exhibit 265.

Mr. March: Is that all, Mr. Gibson?

Mr. Gibson: No.

Mr. Spencer: Are you through with your cross examination of this witness?

Mr. Gibson: Yes.

Mr. March: I have one other question I would like to ask the witness and Mr. Keffer has a few on redirect.

Mr. Gibson: At this point I want to make a motion to strike this exhibit and everything that is said with respect to it.

Analysis of Pressure Decline Method of Estimating Natural Gas Reserves in Texas Panhandle Field.

A. Basic Principles:

"Boyle's Law expresses a simple relationship. It states the fact that the quantity of gas contained within a rigid container varies directly with the absolute pressure. Doubling the pressure doubles the quantity of gas. By increasing the pressure ten times, ten times the quantity of gas can be stored within the container • • •. This law applies strictly to the perfect gas, regardless of the size or shape of the rigid container in which it is confined. Correct calculations can be made from it, however, only when the actual pressure average throughout the entire volume of the container is accurately known." (Gill—Exhibit 265, page 9.)

"A pressure-decline method in which withdrawals of gas are compared to declines of pressure, the latter being weighted only on surface acreages, is entirely incorrect for estimation of reserves of gas in the Texas Panhandle Field." (Gill—Exhibit 265, page 7.)

"According to Boyle's Law pressure varies with volume and not with area unless each area happens to contain the same volume." (Hughes—Exhibit 258, page 6.)

"Volumes (of gas) are not equal in the various areas of the (Texas Panhandle) Field." (Hughes—Exhibit 258, page 11.)

"Hammer • • • has weighted his pressure against areas and not against volumes. • • • he does not have uniform volumes per acre for each quadrant and neither does he have uniform pressures for each quadrant." (Hughes—Exhibit 258, page 11.)

B. Illustrations of Use of Pressure Decline Method in Estimating Natural Gas Reserves:

Testimony of C. Don Hughes
Witness for Canadian.

C. Don Hughes, Witness for Canadian, testified on this subject (Vol. 86, pp. 13086-13121), as follows:

Q. Your name is C. Don Hughes?

A. Yes, sir.

Q. You are the same C. Don Hughes who has testified before in this case?

A. Yes, sir.

Q. Mr. Hughes, I hand you a document and I will ask you if you prepared that instrument in Statement form as an exhibit to be utilized in this case?

A. Yes, sir, I did.

Mr. Keffer: I will ask, Mr. Examiner, that the instrument be marked for identification.

The Trial Examiner: It will be marked for identification as Exhibit No. 258.

(Exhibit 258, Witness Hughes, marked for identification.)

By Mr. Keffer:

Q. Will you proceed and read that statement Demonstration the Pressure decline method.

A. "In order to show how this method is based upon Boyle's Law we refer to Chart 1 where we have three containers of equal size, each containing 20,000 CF of gas, at a pressure of 400#, making a total of 60,000 CF of gas. All of the valves are closed.

Example #1. Suppose we open valves A, B, and C, and then we open valve D and allow 15,000 CF of gas to go out through meter X, in doing this 5,000 CF of gas is removed from each of the containers and, since 5,000 is exactly 1/4th of the 20,000 content then the pressure drops 1/4th or 100# in each container and the remaining pressure is 300# in each container, and the weighted average pressure is the same in all three.

Since the same pressure drop has occurred in each then that is the weighted average pressure drop, or 100#, and with a withdrawal of 15,000 the production per pound drop is 150 CF. Since our original pressure was 400#, then by

multiplying 150 CF per pound by 400# we get 60,000 CF as our computed original amount, which is correct. The correct result is reached because we had an equal volume in each container, and we are in effect weighting pressures against volume.

Example #2. Now, suppose we start out again with the full amount and with all valves closed, and we open valve A, then we open valve D and allow 15,000 CF of gas to flow out through the meter X, all of it comes from A. Since this 3/4ths of the total amount originally in A then its pressure drop will be 3/4th of 400#, or 300#, leaving a pressure of 100# in A.

Now, in order to compute the weighted average pressure remaining in the three we add their pressures, 100# in A, 400# in B, and 400# in C, and find the total of 900# and dividing by 3 find 300# as the weighted average pressure. Thus we see that the weighted average pressure loss is 100# and since 15,000 CF was produced it was at the rate of 150 CF per pound drop and multiplying by 400 gives an original content of 60,000 CF which again is correct. This is true because all of the containers have an equal volume and we are in fact weighting the pressure against volume.

Example #3. Now, instead of going back to the beginning, we start where Example #2 left off, we close valve A, open valve B, leaving valve C closed, then open valve D long enough to let 15,000 CF of gas be produced through meter X; this of course will all be coming from container B.

Since this is 3/4ths of the total originally in B, then the pressure drop would be 3/4ths of 400#, or 300#, leaving 100# pressure in B.

Now, to compute the weighted average pressure of the three containers by adding 100# in A, 100# in B, and 400# in C, we have 600# and dividing by 3 we find 200#. The weighted average pressure has dropped from 300# to 200#, or a loss of 100# with 15,000 CF produced, or 150 CF per pound drop, the same as before.

Multiplying by 400# we get 60,000 CF as original content, which is correct. By this time the grand total production from beginning however is 30,000 CF and with an

overall pressure drop of 200# making 150 CF per pound drop, we again multiply by 400# and get 60,000 CF as the original content, and again, this correct for the simple reason that we have weighted pressures against volume.

Example #4. Now we will carry on from where Example #3 left off. We close valves A, and B, leave C open and then open D long enough to produce 15,000 CF through meter X. Obviously all of this comes from container C and is ¾ths the original content of C hence C has lost ¾ths of its pressure or 300# leaving 100#. We now add 100# in A, 100# in B, and 100# in C, getting 300# and divide by 3 to find the weighted average pressure of the three to be 100#. The weighted average at the end of Example 3 was 200# so we see a drop of 100# during Example 4 with 15,000 CF produced, or 150 CF per pound drop, the same as in the other previous examples. Multiplying by 400# we find 60,000 CF as the original content, again it is correct for the reasons hereinabove stated.

Thus we see that in this setup where the containers are all of equal size we can apply Boyle's Law and get a consistent and correct amount of gas produced per pound drop whether the gas pressure in all containers is going down uniformly or whether it is going down differently in the different containers. Since the examples give the same amount of production per pound drop, then by multiplying by the same original pressure in pounds the computed original content always figures the same and under this arrangement it is correct and is a case where the Pressure-Decline Method works perfectly.

Chart 2. Now we refer to Chart 2 in which we have different sized containers A with 30,000 CF, B with 20,000 CF, and C with 10,000 CF, making a total of 60,000 CF the same as we had on Chart 1. We have the same original pressure of 400# and all valves are closed.

Example #5. Suppose we open valves A, B, and C, then open valve D long enough to produce 15,000 CF of gas through the meter so that 7,500 CF goes out of A, 5,000 CF goes out of B, and 2,500 CF goes out of C. Since 7,500 CF is ¼th of the 30,000 CF content of A then its pressure loss is ¼th of 400#, or 100# leaving 300# pressure in A. Since

5,000 is ¼th of the 20,000 originally in B likewise it loses 100# leaving 300#.

Also since 2,500 is ¼th of the 10,000 originally in C then its loss is 100# leaving 300#. Averaging, we find, A with 300#, B with 300# and C with 300# making a total of 900# and dividing by 3 shows 300# weighted average pressure, or a loss of 100#. With a production of 15,000 CF we find the rate of 150 CF per pound drop and multiplying by 400# shows original content to be 60,000 CF which is correct. The reason it is correct is that the pressures in all three varying sized containers have gone down uniformly. In other words, the pressure was the same in each container.

Example #6. Now to show how with Boyle's Law still acting as it should the Pressure-Decline Method can become inaccurate. Suppose we start in all over with the containers filled and 400# and all valves shut We now open valve A and then open valve D long enough to allow 15,000 CF to be produced through meter X, obviously it all comes from container A, leaving just half of its original content and of course half its original pressure, or 200#.

Now let us add to see what the weighted average pressure is, A with 200#, B with 400#, and C with 400# totaling 1,000# divided by 3 gives 333-1/3# weighted average pressure. Subtracting from 400# shows a weighted average pressure drop of 66-2/3# while 15,000 CF were being produced at a rate of 225 CF per pound drop, and multiplying by 400# gives 90,000 CF as original content which we know to be wrong since we started out with the set amount of 60,000 CF.

The thing which got us into trouble here is that we weighted each container in order to get a weighted average pressure without taking into account that the containers are different in size. What we really need to know is the equilibrium pressure which would result if all the containers were allowed to equalize, that is, if we insist on using some weighted average pressure knowing that the containers differ in size and if we do not know how they differ. In other words, we arrived at an average weighted pressure by considering area rather than volume. Accord-

ing to Boyle's Law pressure varies with volume and not with area unless each area happens to contain the same volume."

Q. Right in that connection, Mr. Hughes, in averaging pressures in the field such as Mr. Hammer averaged them and such as the Railroad Commission of Texas averaged them, you are as a matter of fact weighting your pressures against areas, are you not?

A. Yes, that is right.

Q. And is it true or not that different areas in the Panhandle field vary widely with respect to gas content?

A. Yes, it is true that the content does vary widely.

Q. You may proceed.

A. "Example #7. But coming back to show why 333-1/3# although it is a weighted average pressure based merely on numbers of containers (each containing the same surface area) is not the same as the equilibrium pressure which we want, suppose at the end of Example #6 we let valve A open (D of course still remains closed) then we open valves B and C. Gas will move from containers B and C into container A. However, now gas will be produced into meter X since valve D remains closed. Container B will furnish 5,000 CF and container C will furnish 2,500 CF making a total of 7,500 which will migrate into A. After B has furnished 5,000 it will have 300# pressure instead of 400#. After C has furnished 2,500 it will have 300# pressure instead of 400# and then when A has received the combined amount of 7,500 it will have 300# instead of 200#. In other words the whole system will have become equalized at 300# which is also the arithmetic weighted average pressure after equalization. We have seen that the system has not been allowed to produce any gas yet its new weighted average pressure is 300# instead of the 333-1/3# weighted averaged at the beginning of the period of equalization. Thus without any production the weighted average pressure has declined 33-1/3#. This decline leads to an absurdity, where with no production the pressure loss is 33-1/3#, the rate becomes zero per pound drop and multiplying by 400# we find zero as the original content.

Example #8. Suppose we start again where Example 6 ended, with a total production of 15,000 having been taken

out of A, with B and C still untouched, we found that gave 66-2/3# drop or 225 CF per pound drop, and indicated an original content of 90,000.

From that given situation let us produce enough from each container to result in a 100# drop in each, from where they were at the end of Example 6.

In order to do this A would be permitted to produce 7,500 out through the meter and in doing this its pressure would drop 200# to 100#. B would be permitted to produce 5,000 out through the meter and in doing this its pressure would drop from 400# to 300#. C would be permitted to produce 2,500 through the meter and while doing it its pressure would drop from 400# to 300#. The total amount produced from the entire system during this procedure would be 15,000 CF. The remaining weighted average pressure would be found by adding A with 100#, B with 300#, and C with 300#, totaling 700# and dividing by 3 gives 233-1/3#.

Subtracting this from 333-1/3# leaves 100# as the weighted average pressure loss. With 15,000 CF produced during this loss the rate is 150 CF per pound drop instead of 225 CF per pound drop in Example 6. Since each container lost the same number of pounds during example 8 the result of that calculation came out correct, namely 150 CF per pound drop, and multiplying by 400# indicates 60,000 CF original content, which we know to be correct, instead of the wrong figure of 90,000 found in Example 6. In other words the pressure drop in each container was identical

Example #9. At this point it is important to show that, while we obtained the correct figure from a study of the interval in Example 8, we would still have an erroneous result if, instead of using that interval alone, we would have gone back and computed by the overall method from the beginning.

The overall method would combine the results of Examples 6 and 8, namely, container A had produced 22,500 CF with a remaining pressure of 100#; B had produced 5,000 CF with a remaining pressure of 300# and C had produced 2,500 CF with a remaining pressure of 300#. Thus we had a grand total production of 30,000. We now add the pres-

sures, A with 100#, B with 300#, and C with 300#, totaling 700# and dividing by 3 find the weighted average pressure to be 233-1/3# (identical with that found previously as at the end of Example 8).

The total loss in pounds from 400# is 166-3/3# and with a production of 30,000 we find we had produced 180 CF per pound loss. We observed in Example 8 that the correct production should be 150 CF per pound drop and that it was indicated by using merely one interval during which each container lost the same number of pounds pressure. Therefore, to go back and average in everything from the beginning does not increase the probability of accuracy, in fact this proves definitely that it has lead away from a correct figure to an erroneous one. But referring to the 180 CF indicated production per pound drop and multiplying by 400# we find at the end of Example 9 the indicated original content of 72,000 CF.

Here we see the effect of early production coming from the richest container leading to an erroneously high figure of original content being 90,000 instead of the known correct figure of 60,000. During the next stage of production some was taken from leaner containers and by the overall method the computed original content has dropped from 90,000 to 72,000 but still not know the correct figure of 60,000.

Conclusions From the 'Text Book' Examples.

1. If the pressure-decline method is working correctly it shows a constant amount of gas produced per pound pressure drop, whether computed on any one of several intervals or by going back to the beginning each time.

This is accomplished when each container is equal in size (Chart 1) whether the pressures in each are going down *iniformly* (Example 1), or going down in varying amounts (Example 2).

It is accomplished with containers of unequal size (Chart 2) only when the pressures in each are going down uniformly (Example 5) or when for a given interval the pressure loss in each container is the same (Example 8).

2. If the pressure-decline method is not showing a con-

stant rate of production per pound drop in pressure then it is due to the fact that we are having unequal pressure drops in containers having unequal content (Chart 2). This is shown by Examples 6, 7 and 9.

3. It further shows that, if that rate of production per pound pressure loss is declining with successive periods, then the early production was coming from larger containers than those furnishing the later production, or at least it shows that some production was beginning to come from smaller containers. This is shown by Examples 6 and 9.

Chart 1 has heretofore been marked as Exhibit 188 and Chart 2 as Exhibit 189 and referred to as such during the cross examination of Federal Power Commission witness Hammer.

The pressure decline method as applied by Mr. Hammer cannot give the correct answer because pressures are not equal in the Panhandle of Texas gas fields and for the further reason that the volumes are not equal in the various areas of the field. Mr. Hammer has attempted to secure a weighted pressure in the field by taking the area of each segment between isobar lines and multiplying this by the pressure obtaining in each segment as to each quadrant and then dividing each quadrant total by the number of acres in the quadrant.

This method necessarily assumes that each segment as outlined by the isobar lines in any given quadrant contains the same volume of gas per acre as every other segment in the quadrant. This obviously is a false assumption. Mr. Hammer therefore has weighted his pressures against areas and not against volumes.

The grouping of quadrants as illustrated by Federal Power Commission Exhibit No. 180 could not possibly correct this error for the reason that in each of the quadrants the volume varies over the areal extent of the quadrant. In other words, he does not have uniform volumes per acre for each quadrant and neither does he have uniform pressures for each quadrant. This being true he could not possibly

arrive at the correct estimate of reserves of gas in place by the application of the pressure decline method as he applied it.

[Exhibit 188, Chart, appears at page 3883.]

[Exhibit 189, Chart appears at page 3887.]

The Pressure-Decline Method
in the
Texas Panhandle Gas Field.

Based upon a strict assumption that the Panhandle Reservoir is 100 per cent volumetric control, a critical examination has been made of the Pressure-Decline Method.

The pressure figures used in the computations are the weighted averages found by the Texas Railroad Commission. The first field-wide survey was conducted by the Commission in the summer of 1935. A second one was made in January 1936 and due to winter operating conditions it was considered less accurate and involved unnecessary inconveniences and therefore the winter survey was discontinued in favor of an annual one in the summer.

During the contouring of the 1940 pressure map this fall by the Railroad Commission, an error was discovered in the 1939 map. The error affected some 30 sections of land in southeast Gray County where the pressures on the 1940 map are necessarily raised over what they were on the 1939 map. It is due to new control shown by the Lone Star Fowler wells in Section 118 Block H&GN. The wells which gave the new control for the 1940 map had a drop in pressures during the years as follows:

Lone Star Fowler #1 8-1-39 pressure 323#, 8-1-40 pressure 304#:

Lone Star Fowler #2 8-1-39 pressure 322#, 8-1-40 pressure 303#.

The pressure drop in each was 19 pounds.

I presume it was an oversight that those pressures were not used on the 1939 map. At any rate this shows that the weighted average pressure for 1939 was wrong. Had the

pressures in these wells being used the weighted average would have been some higher than was found and reported by the Commission. This would have caused a smaller drop in the weighted average pressure from 8-1-38 to 8-1-39 and consequently a larger drop between 8-1-39 and 8-1-40 than exists in the published figures.

Therefore for lack of a correct figure for 1939; or rather due to the known fact that the 1939 figure is in error, I am ignoring it and in the following study am treating the two-year period 8-1-38 to 8-1-40 as a unit whose production resulted in the pressures accepted as being correct at the date 8-1-40.

Chart "A".

If the Pressure-Decline method were working correctly, the production per pound drop in pressure would be constant, that is, at any given pressure survey date the cumulative production divided by the overall pressure loss would give a constant figure.

Date	Cumulative Production Mcf.	Pressure Loss From 430#	Production Mcf. per Pound Drop
8-1-35	5,197,693,413	67.49=	77,014,270
7-1-36	5,754,179,067	75.00	76,722,387
7-1-37	6,307,060,469	82.95	76,034,484
8-1-38	6,929,985,630	92.34	75,048,577
8-1-40	8,082,404,377	111.69	72,364,620

The fact that the production per pound drop is not constant proves conclusively that the pressure-decline method is not working correctly in the Texas Panhandle.

The downward trend in the rate of production per pound drop is shown graphically on the accompanying Chart "A". If the pressure-decline method were working correctly that downward trending curve would be a horizontal straight line.

Chart "B".

If the pressure-decline method were working correctly, the rate of production per pound drop computed by the overall method at any given pressure survey date could be multiplied by the total number of pounds original pressure

and obtain a constant figure indicating the total original Reserve.

Date	Rate of Production in MCF per Pound Drop Overall Method	Orignal Reserve MCF Obtained by Multiplying Rate per pound by 430#
8-1-35	77,014,270	33,116,136,100
7-1-36	76,722,387	32,990,626,410
7-1-37	76,034,484	32,694,828,120
8-1-38	75,048,577	32,270,888,110
8-1-40	72,364,620	31,116,786,600

The figures indicating original reserve are not constant and this fact proves conclusively that the pressure-decline method is not working correctly in the Texas Panhandle; the importance and significance of the downward trend in the computed original reserve is shown on Chart "B".

If the method were working correctly that downward trending curve would be a horizontal straight line until it finally intersected an extension of the 45 degree sloping line.

Chart "C".

If the pressure-decline method were working correctly, the rate of gas produced per pound pressure drop would be the same for any or all intervals or periods between pressure surveys, that is, the rate "currently" would be constant.

Period	Production During Period MCF	Pressure Loss During Period	Production Mcf. per pound loss during period or "currently"
Beginning to 8-1-35	5,197,693,413	67.49	77,014,270
8-1-35 to 7-1-36	556,485,654	7.51	74,099,288
7-1-36 to 7-1-37	552,881,402	7.95	69,544,830
7-1-37 to 8-1-38	622,925,161	9.39	66,339,208
8-1-38 to 8-1-40	1,152,418,747	19.35	59,556,524

The current production per pound drop is not constant and this shows conclusively that the pressure-decline method is not working correctly in the Texas Panhandle. This rapidly declining rate of production per pound loss is shown plotted against accumulated production on Chart "C".

If the pressure-decline method were working correctly this would be a horizontal straight line.

The importance of this curve is discussed at length toward the end of this report.

My observation for several years has been that the production in the early life of the field came from richer than average areas and the pressure loss at that time was in those areas and hence an application of the pressure-decline method would give an estimate of original reserve that is too high.

I have maintained that the remaining high pressure areas were lean and when they finally came into depletion their pressures would drop faster with a continually lowering of the estimate of original reserve by the pressure-decline method.

There are still large areas of high pressure lean acreage which can cause this decline in rate of production per pound drop to continue into the future.

Our reservoir is not a perfect container and migration is restricted in some areas. Unequal withdrawals have caused unequal pressure declines in various parts of the field. I believe the declines as a whole have been in richer than average areas and if the entire field were shut in today until the pressures became equalized, the final pressure would be less in pounds than our present so-called weighted average pressure. Theoretically it is this equilibrium pressure that is needed (and which we do not have) in order to apply Boyle's Law correctly to the container.

In opposition to this, it has been pointed out by some who are trying to use the pressure-decline method in the Panhandle that even though the original content of gas did vary in the field, still the variation would average out in all pressure bands. That is, within each pressure band at any date they are so widespread and include all kinds of acreage good bad and average, that any given band is typical of the field.

Now, if by chance this does happen to be true, then the situation is more serious than I have suspected.

For if this be true, then the pressure-decline method should be working perfectly, giving constant results.

Obviously it is not working out that way and in order to explain why it isn't we must admit some situation to exist in the reservoir which is causing an ever lessening amount of production per pound drop.

This decline in the amount of production per pound drop has been going on throughout the entire period in which we have the official pressure surveys, from August 1935 to the present, August 1940. This is the period in the history of the field in which we have the best information, both as to pressures and production.

It appears logical to project into the future this changing rate of production per pound drop.

This would be done by extending the five year control curve on Chart "C" as a downward trending straight line.

The extension would intersect the base line at about 18 trillion cumulative production which at first thought might be interpreted as the indicated original reserve.

However, if these declining rates of production per pound drop be actually set up in table form and the necessary drop in pressure required during a given amount of production is computed it will be found that the field is at zero pressure when the cumulative production is about 16.3 trillion.

Summary:

1. It is apparent that the pressure-decline method is not working correctly in the Texas Panhandle. This is not subject to argument. I recognize Boyle's Law and I have not upset any law in physics in proving that the method is not working correctly, in fact I have used Boyle's Law to prove my conclusions.

2. I have shown a valid reason why the pressure-decline method is not working correctly, and if my reason is sound, conditions still exist which will cause the downward trend in production per pound drop to continue into the future.

Such a continuation points to an estimate of original reserve of 16.3 trillion cubic feet of gas.

This critical study of the pressure-decline method re-

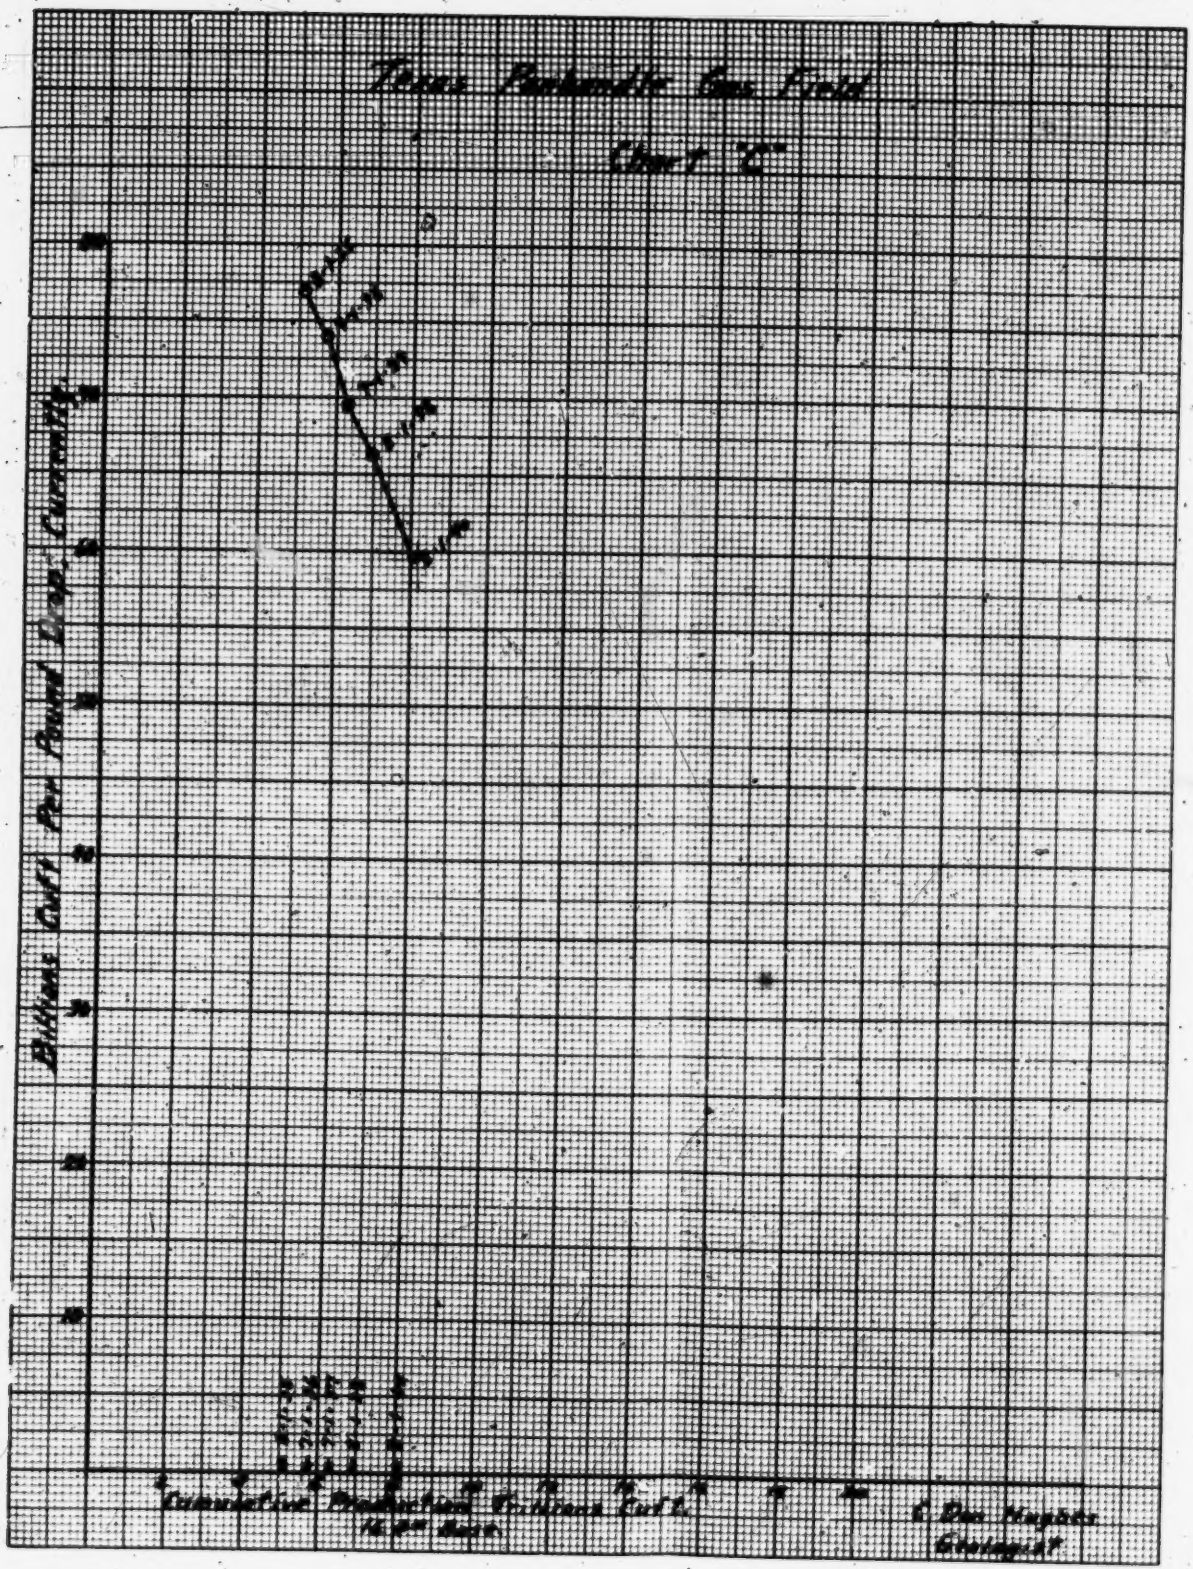
veals a steady decline in the rate of production per pound drop.

While it shows positively that the orthodox manner of using the method cannot be relied upon, since it gives a different answer each time, still it is believed that the definite rate of change in the production per pound drop is significant.

Therefore, this study shows that the method does not give a reliable answer at any one date, but that it becomes a guide for the future by extending the changing rate of production in accordance with actual performance during the past five years.

An extension of this trend points to an original reserve of 16.3 trillion for the field. If this is correct, then my estimate of approximately 19¼ trillion is too high. Even though this is the indication, I am inclined to stand on the evidence that 19¼ is a reasonable figure and that the manner in which I arrived at it is reasonable. However, in the light of contemporary trends in the downward rate of production per pound drop in the reservoir it may be that a new angle has developed, the effect of which should be incorporated in a revision downward of my 90 per cent recovery factor.

Exhibit No. 258



Pressure Decline Method.

Using Mr. Hammer's Quoted Production Prior to 8-1-35, his production figures from 8-1-35 to 8-1-39 and weighted average pressures for the field at the two dates computed from Mr. Hammer's working papers.

By using data in Mr. Hammer's working papers I have computed the weighted average pressures for the Panhandle field, including Wheeler County Quadrant I, at 8-1-35 and found it to be 369.10 pounds, or a drop of 60.90 pounds from original 430 pound pressure.

Using this data, I also computed it for 8-1-39 as 331.73#, including Wheeler County Quadrant I, or a drop of 98.27 pounds from original pressure of 430 pounds.

Mr. Hammer has entered a figure of 4,833,608,743 Mcf. quoted by him as being the cumulative production for the field prior to 8-1-35 arrived at by the Phillips Petroleum Company.

He showed as his own metered production for the period 8-1-35 to 8-1-39 from records of the Texas Railroad Commission 2,430,370,036 Mcf.

I have made a study of this basic data in order to see what he would have arrived at, in comparison with my results, had he applied the pressure decline method in the orthodox manner, that is, treating the field as a whole and computing the production per pound drop in pressure.

In order that these results could be compared with my results I have converted his 14.65 pound pressure figures to 16.4 pound base.

Multiplying 4,833,608,743 Mcf. by .892329 gives 4,317,814,354 Mcf. 16.4# base.

Multiplying 2,430,370,036 Mcf. by .89329 gives 2,171,025,249 Mcf. 16.4# base.

Using the pressure-decline method, the production at 8-1-35 of 4,317,814,354 Mcf. was divided by the pressure loss at 8-1-35 or 60.90 pounds, indicating a production per pound drop of 70,900,071 Mcf. This rate of production per

pound loss was multiplied by 430 pound original pressure resulting in 30,487,030,530 Mcf. as an estimate of original reserves down to zero wellhead.

Now to test the reliability of the method we add the production for the 4-year period (8-1-35 to 8-1-39) to the production prior to 8-1-35, or 2,171,025,249 Mcf. plus 4,317,814,354 Mcf. and get a cumulative production of 6,488,839,603 Mcf. for the entire period prior to 8-1-39. Dividing that by the total pressure loss of 98.27 pounds at 8-1-39 we find a production of 66,030,728 Mcf. per pound loss which is much less than we found before and which shows that the pressure-decline method is not working correctly. We should have obtained a figure approximately the same as we had for the first period. Multiplying this lesser amount of production per pound loss by 430 pounds we get an estimate of original reserves of 28,393,213,040 Mcf., further showing that the method is not giving a consistent estimate.

In order to visualize this changed estimate the information has been plotted on charts which also show the answers I arrived at when I used our production data and the weighted average pressures for the field as found by the Texas Railroad Commission.

On Chart "A"1 I have plotted with small triangles, as the indicated control points, the results obtained using Mr. Hammer's data showing definitely the lessened rate of production per pound loss along with his cumulative production for the field. It can be readily seen that his own production and pressure figures show a faster changing rate than the one we have with our figures.

On Chart "B"1 I have, with similar symbols, plotted the resulting estimates of original reserves arrived at with his figures as compared with those arrived at with ours. Again it is noticeable that as plotted against cumulative production on the horizontal scale the indicated original reserve figure had dropped more rapidly than our figures had.

It is quite evident on Chart "B"1 that if the rate of change based on his data continues, then I have overestimated the reserves when I show 19¼ trillion.

Now we will test the performance of the field on what Mr. Hammer states is the only accurate history we have, that is, his 4-year period, 8-1-35 to 8-1-39.

His production of 2,171,025,249 Mcf. is divided by his pressure loss for the period (369.10# — 331.73# = 37.37#) of 37.37 pounds showing a production per pound loss of 58,095,404 Mcf., which is surprisingly low compared with the 70,900,071 Mcf. per pound loss shown by his data for the period prior to 8-1-35.

Multiplying the production per pound loss for the 4-year period by 430 pounds, we find an estimated original reserve of 24,981,023,720 Mcf., which again is quite in contrast with the 30,487,030,530 Mcf. arrived at, using the period prior to 8-1-35.

In order to visualize these data I have plotted the changed rate of "contemporary" or "current" production on Chart "C" 1 where it can be seen not only in its own light but in comparison with a similar downward trending rate shown by our figures.

This evidence on Chart "C" 1 is very significant. It shows both with his data and our data that the production per pound pressure loss is declining very rapidly.

If this rate exhibited by Mr. Hammer's data is extended as a straight line and if increments of production identical with this 4-year period are added to the cumulative production then it is possible to read from the extended line the rate of production per pound drop which might be expected. By dividing this rate into the increment of production, the number of pounds pressure loss can be computed for each increment. By subtracting this pressure drop from the pressure at the beginning of the increment then the remaining pressure can be computed.

This has actually been done and it shows that the pressure of the field is exhausted when the cumulative production is approximately 14.3 trillion cubic feet. The number of increments necessary to bring that about is approximately $3\frac{1}{2}$ and if those increments of production are assumed to take place during four years each, as his actually did, then the computed years involved would be approximately 14 years after 8-1-39.

Another phase of the study consists of using annual production for the field totaled from Mr. Hammer's working

papers and annual weighted average pressure drops computed from his working papers. The production was converted from 14.65# base to 16.4# base using the factor .89329.

Period	Production Mcf. 14.65# base	Production Mcf. 16.4# base
8-1-35 to 8-1-36	620,404,940	554,201,528
8-1-36 to 8-1-37	595,387,041	531,853,290
8-1-37 to 8-1-38	616,439,219	550,658,990
7-1-38 to 8-1-39	598,138,836	534,311,441
	2,430,370,036	2,171,025,249

The pressure drop for each period was found by subtracting the weighted average pressures at the end of each from that at the beginning of each period.

Period	Weighted Average Pressure	Pressure Drop
8-1-35	369.10#	
8-1-35 to 8-1 36	359.86	9.24#
8-1-36 to 8-1 37	350.95	8.91
8-1-37 to 8-1:38	341.87	9.08
8-1-38 to 8-1-39	331.73	10.14

The production for each period was divided by the pressure drop to determine the rate of production per pound drop.

Period	Production MCF 16.4# Base	Pressure Drop	Production Per Pound Drop MCF 16.4#. Base
8-1-35 to 8-1-36	554,201,528	9.24	59,978,520
8-1-36 to 8-1-37	531,853,290	8.91	59,691,727
8-1-37 to 8-1-38	550,658,990	9.08	60,645,263
8-1-38 to 8-1-39	534,311,441	10.14	52,693,436

The rate of production per pound drop was steady during the first three periods but dropped sharply during the last period, this may be visualized on Chart "C" 1 where it has been plotted as a curve controlled by small squares at each point.

This information was plotted against cumulative production from 8-1-35 on the horizontal scale.

It is readily seen that the net effect of these annual rates of production per pound drop shows a decided decline at the end of the priod, an average curve through these four points would slope downward nearly parallel with the other two curves on Chart "C" 1. This confirms the slopes of the other two.

The cumulative figures from 8-1-35 for use on the horizontal scale follow:

Period	Production for Period MCF 16.4# Base	Cumulative from 8-1-35, MCF 16.4# Base
8-1-35 to 8-1-36	554,201,528	554,201,528
8-1-36 to 8-1-37	531,853,290	1,086,054,818
8-1-37 to 8-1-38	550,658,990	1,636,713,808
8-1-38 to 8-1-39	534,311,441	2,171,025,249

The rate of production per pound drop annually may be multiplied by 430 pounds giving an estimate of original reserves for the field:

Period	Production Per Pound Drop MCF 16.4# Base	Original Reserves To 0# Gauge MCF 16.4# Gauge
8-1-35 to 8-1-36	59,978,520	25,790,763,600
8-1-36 to 8-1-37	59,691,727	25,667,442,610
8-1-37 to 8-1-38	60,645,263	26,077,463,090
8-1-38 to 8-1-39	52,693,436	22,658,177,480

Referring again to the declining rate of production per pound pressure loss as plotted on Chart "C" 1 with the small squares as the control points the trend has been extended into a sloping straight line.

If this declining rate of production continues in accord with the extended curve then the following will be the result.

When the cumulative production on the horizontal line has reached 3 trillion the rate of production for the increment of production of 828,974,751 Mcf. which brings the cumulative total to 3 trillion will be about 47.5 billion per pound. Dividing this into the production increment shows that a 17.45± drop will be necessary. If we subtract this

from the existing pressure at 8-1-39 it leaves 314.28 as the remaining pressure.

By continuing this procedure in increments of 1 trillion each it is found that the pressure will be exhausted when the cumulative production is slightly over 9 trillion. If we subtract the approximately 2 trillion, cumulative production at 8-1-39 it leaves 7 trillion.

Mr. Hammer shows the total production for the 4-year period as 2,171,025,249 (16.4# base) or an average of approximately 543 billion per year.

Dividing the remaining 7 trillion at 8-1-39 by 543 billion shows approximately 13 years indicated to take the field down to zero pressure wellhead."

Q. I have just a few questions. Mr. Hughes, if you wil refer to your Chart "C" 1 that follows Page 24 of your Exhibit 258. You have shown three curves there. The furthest curve to the right is based upon the Railroad Commission's figures, is it not, for those respective years as indicated upon the curve?

A. Yes, that is right.

Q. The middle curve is based upon Mr. Hammer's figures for the period August 1, 1935 to August 1, 1939, but is not broken down into years?

A. That and the period prior to 1935. That curve is based upon—

Q. That curve to the left shows Mr. Hammer's figures year by year, doesn't it?

A. That is right.

Q. If you extend that curve as you have stated through the year 1939, we will say, and through the circle representing 1937 and approximately half-way—we should say between the circles representing 1938 and the circle representing 1936—you get the curve that is projected as you have shown it?

A. That is right.

Q. Now, Mr. Hammer's curve on his figures show a slight increase in production per pound drop for the period from August 1, 1937 to August 1, 1938?

A. That is right.

Q. Could that be accounted for by Mr. Hammer's failure

to take into account quantities of gas that have been produced and not metered?

A. Yes, assuming that his contouring of the maps of those different dates and planimetering and all might not account for some of that variation.

Q. Could—there could very easily be mistakes made in matters of that kind no matter how careful you were?

A. That is right.

Q. That slight increase is not shown on the Railroad Commission's figures on the curve to the right?

A. No.

Q. The curve farther to the right on that chart?

A. No.

Q. Now, just one or two more questions.

Will you go back to Chart A on Page 14. Now you show production in Mcf. per pound drop in pressure covering the entire field in the table on Page 14, do you not?

A. That's right.

Q. That's right. It starts out at 8-1-35, .77 billion per pound drop in pressure—77 billion cubic feet—that's right—and taking 1-19-40, it has dropped to a little more than .72 billion per pound drop in pressure.

A. That is right.

Q. But now those are cumulative figures, are they not?

A. Yes.

Q. That's right. When you get your 77 billion at 8-1-35 you have taken all production from the beginning of the field up to that time, is that correct?

A. Yes.

Q. And when you get your 76 plus billion per pound production in 1936 you have taken the entire history of the field up to that time?

A. Yes.

Q. And likewise you have taken everything back of each year and brought it up to the year which you have shown here, is that correct?

A. Yes, that is right.

Q. Now, if you had broken that down into years you would have gotten a much greater decline in your rate of production per pound drop, wouldn't you?

A. Yes.

Q. Now, that is shown on Chart "C", that is, I mean on Page 16, your table set out on Page 16, which discusses Chart "C".

A. That's right.

Q. Now, you will notice there at 8-1-35 you have 77 billion plus cubic feet per pound drop which is the same figure which you had on the chart on Page 14, isn't it?

A. That's right.

Q. When you divide that up into years, get the per-pound drop for each year for the period of 8-1-38 to 8-1-40, instead of the 72 billion plus, which you show on Page 14 and which is cumulative for those two years, you get 59 billion plus, is that not correct?

A. That is right.

Q. Showing that each year as you go forward, no matter where you start, you get less production the following year than you did the preceding year per pound drop in pressure, is that correct?

A. That is correct.

Mr. Keffer: I merely wanted to explain, Mr. Examiner, the difference between the cumulative figures and the figures from year to year. I wasn't sure that it was as clear as it might be.

Q. Now, on that same basis, referring to Page 15, you show there, using the pressure decline method, the different answers that you would get if you would make reserve estimates at different periods, do you not?

A. That's right.

Q. And it goes from 33 trillion plus to 31 trillion plus?

A. Yes.

Q. But those are again cumulative, aren't they?

A. That's right.

Q. That's right, when you make the estimate on this basis at 8-1-40, you have taken everything back of 8-1-40 to the beginning, is that correct?

A. That's right.

Q. Now, when that is broken down again into years—well, I don't see where you have made an estimate on that, but go back to Page 16. If you were to make an estimate for the 2-year period, 8-1-38 to 8-1-40, in which you have a little less than 60 billion production per pound drop in

pressure, your estimate, instead of being 31 trillion, plus, as shown on 15, would be something in excess of 25 trillion, wouldn't it?

A. Yes, it would be.

Q. Just roughly?

A. It would be 430 pounds times this.

Q. 59 plus?

Mr. March: 59 plus, billion?

Mr. Keffer: That's right.

The Witness: That's right.

By Mr. Keffer:

Q. Now, those same general observations I think would apply to Mr. Hammer's figures which you also show on your subsequent charts, in your exhibit, but I want to call attention to just one thing.

If Mr. Hammer had made his estimate based upon production and decline in pressure for the period 8-1-38 to 8-1-39, he would have had; as shown by Page 26, a pressure drop of 10.14 pounds, wouldn't he?

A. Yes.

Q. On Page 27 he shows production of 534 billion plus, or a production of 52 billion plus per pound drop in pressure.

A. That is right.

Q. That is on 16.4 base?

A. Yes.

Q. Now, if he had made his estimate for that period, you would have the figure as shown on the second table on Page 28 which is 22 billion—I mean 22 trillion—658 billion original reserve on a 16.4 base?

A. That is right.

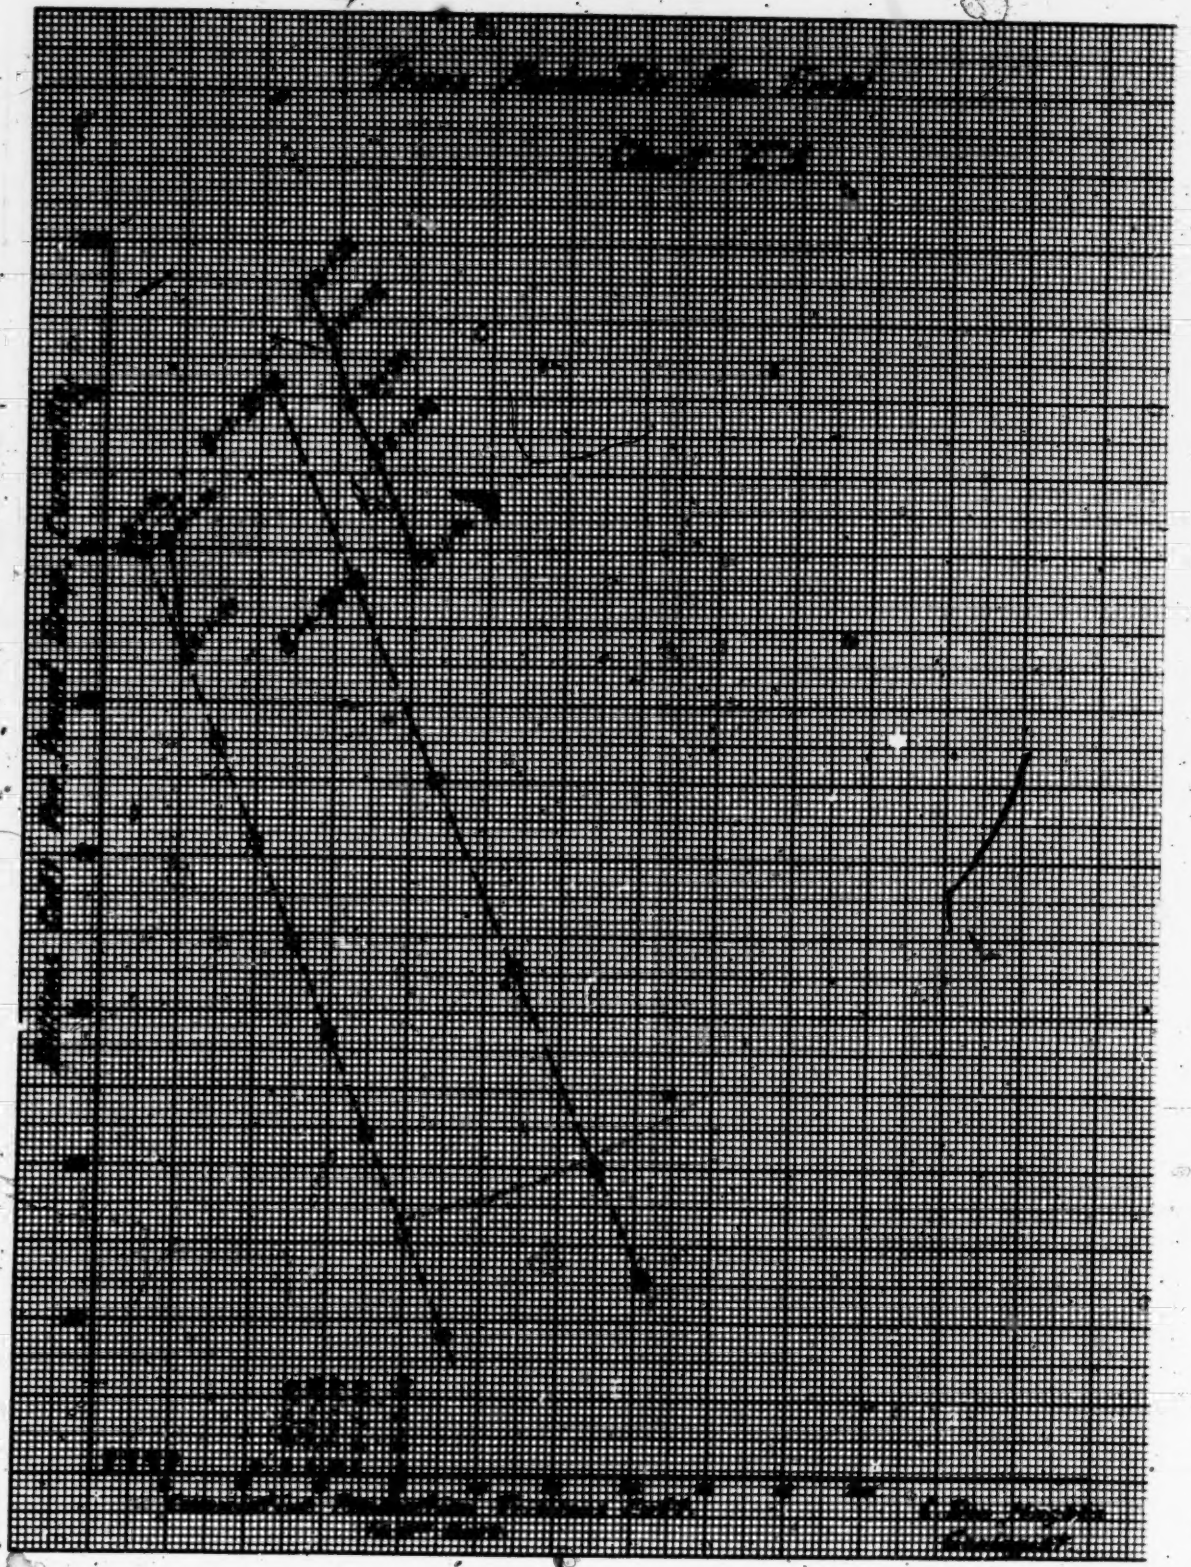
Q. That is the figure that he would get if he had used the last available data for a complete year?

A. That is right.

• • • • •

Exhibit 258.

4515
Exhibit No. 258



Hughes made a further study of Hammer's estimate of reserves with particular reference to the utilization of quadrants by Hammer. This study is contained in Exhibit 264 and the testimony in connection therewith in Volume XCIV, pages 14462 to 14476.

Exhibit 264 contains tables A and B which are based upon the working papers of Hammer.

There is also attached to the Exhibit two maps which are exact duplicates of Hammer's isobar map, Exhibit 179. The first of these maps shows the various counties of the field colored in red and in green. The counties colored green are the counties which have gained gas by migration as reflected by Hammer's data. The counties colored in red indicate the counties that have lost gas by migration, as indicated by Hammer's data. The second map follows the same color scheme as to quadrants and shows the quadrants as outlined on Hammer's isobar map, Exhibit 179, which have gained gas by migration, colored green, and those which have lost gas by migration, colored red, all as disclosed by Hammer's data.

The Exhibit itself contains a detailed explanation of the various figures set out in Tables A and B.

The calculations made by Hughes show, according to Hammer's data, that Wheeler County has lost in excess of 48 billion cubic feet of gas by underground migration during the four-year period covered by Hammer's data. The only place that this gas could have drained to would be Gray County since there are no other counties in the field adjoining Wheeler County. The gas, therefore, would have migrated from a lower pressure area to a higher pressure area as shown by the isobar configurations on Hammer's Exhibit 179. (Vol. XCIV, pp. 14464-14465.)

Gray County lost almost 14 billion cubic feet of gas by migration, and this, plus the 48 billion which it gained from Wheeler County, makes a total of 62 billion cubic feet that migrated out of Gray County. The only possible place for this gas to go would be Carson County to the west. Hammer's map, Exhibit 179, shows the pressures to be higher in Carson County than in Gray County. There

fore, this volume of gas necessarily migrated from a low pressure area to a higher pressure area. (Vol. XCIV, p. 14465, 14466.)

Carson County lost almost 163 billion cubic feet of gas during the four-year period. It had gained 62 billion cubic feet from Gray County which made a total of approximately 225 billion cubic feet that migrated out of Carson County. Some of this gas could very logically have gone into Hutchinson County, but not all of it, since Hutchinson County gained approximately 134 billion cubic feet. This left approximately 91 billion cubic feet that Hutchinson County might have received from Carson County, which necessarily migrated to some other county. (Vol. XCIV, pp. 14467-14468.) This gas could not go to Potter County since Potter County also lost 27 billion cubic feet approximately. The only place it could go would be Moore County. There migrated into Moore County, therefore, the approximate 91 billion cubic feet left out of the gas Hutchinson County received from Carson County, plus the 27 billion cubic feet that migrated out of Potter County into Moore County. It is evident, therefore, that Moore County received approximately 118 billion cubic feet of gas by migration from Hutchinson and Potter counties. Moore County, as shown by Hammer's map, Exhibit 179, has a higher pressure than Hutchinson County. (Vol. XCIV, pp. 14467, 14468.)

All of the above calculations are shown in tabulated form on page 5 of Exhibit 264. Hughes stated that, assuming Hammer's data were correct, it actually showed that substantial volumes of gas had migrated from Wheeler County to Moore County. (Vol. XCIV, pp. 14468, 14469.) Hughes stated, however, that he did not mean to imply that gas had actually migrated from Wheeler County to Moore County, or that gas migrated from low pressure areas to high pressure areas, which is indicated by a study of Hammer's data. He explained the absurd situation which results from a consideration of Hammer's data by the fact that Hammer's estimates of gas in the various quadrants of the field are erroneous. It is Hughes' opinion that the weighting and averaging process used by Hammer had the effect to aggravate or overestimate the gas actually

in place in many of the quadrants of the field. It is the witnesses' opinion, however, that the study does show that Hammer's estimate of reserves for the various quadrants and for the field as a whole based upon this method, is entirely erroneous (Exhibit 264, page 5 to 8.)

Hughes testified that there is no drainage in or out of the Texas Panhandle Field as a whole and that Hammer could have applied his data to the field as a whole without dividing the field into quadrants. If he had treated the field as a whole and disregarded quadrants then Hammer's data would have resulted in an estimate of approximately 28 trillion cubic feet to zero pounds wellhead on a 14.65 pound pressure base, but that the method of estimating reserves for each quadrant, and then adding these various estimates to determine the estimate for the field resulted, on Hammer's data, in an estimate of approximately 31 trillion cubic feet. Hughes does not agree that the 28 trillion cubic feet is the correct estimate, but merely states that by using the same data Hammer increased his estimate by approximately 3 trillion cubic feet by the division of the field into quadrants. (Vol. XCIV, pp. 14474-14475.)

Cross Examination on Exhibit 258.

On cross examination Hughes again reiterated that the pressure-decline method as applied to the Texas Panhandle Field would give approximately the correct result if there were any method whereby the correct weighted average pressures could be obtained. The correct weighted average pressures cannot be obtained by weighting on acreage alone; in order to get the correct weighted average pressure it should be weighted on volume, not on acreage. (Vol. XCIV, p. 14503.)

Hughes again explained the error that was made by the Railroad Commission in contouring its 1939 pressure map and stated that this error was called to his attention by the Railroad Commission staff. He stated further that if he had used the 1939 pressure figure that the curve which is shown on Chart C, Exhibit 258, would have declined much more from 1938 to 1939 than it did for the period from 1938 to 1940. (Vol. XC., pp. 13810-13822.) Hughes did not attempt to correct the error because this

could only have been done by recontouring the entire field which he did not do. (Vol. XC, p. 13823.) Although the wells upon which the error was made were located on the east field, it affected the weighted average pressure on the entire field. (Vol. XC, p. 13826.)

The witness stated that he had been applying the pressure-decline method to the Texas Panhandle Field since the Railroad Commission had been putting out weighted average pressures, but it did not give consistent results; that he would not shut his eyes to the definite trend which the pressure-decline method showed and that if this trend continued in the future as it had in the past five years that this method would point to an original reserve in place of 16.3 trillion cubic feet. (Vol. XC, pp. 13842-13844.)

It is the witness' opinion that if the field were shut in and pressures were permitted to equalize that the equalized pressure would be less than the Railroad Commission's weighted average pressure and less than Hammer's weighted average pressure, and that one reason that this would be true is the fact that the high pressures now obtaining in the field are located for the most part in the lean areas; that is, areas that have less than the average volume of gas in place; (Vol. XCI, pp. 13881-13883) and that the difference in the so-called weighted average pressure and the equilibrium pressure would probably be quite a sizable difference. (Vol. XCI, p. 13884.)

The witness was referred to Chart C-1, which contained a graph based upon Hammer's pressure and production figures. He stated that the decline from 1938 to 1939 was not unusual because it corresponds with other data with which he has compared it. He thinks it is more likely that the pressure declines with respect to production in some of the earlier years covered by Hammer's study are more likely to be unusual. (Vol. XCI, pp. 13901-13904.) He made a reasonable interpretation of the data shown on Chart C-1 in drawing his curve based upon such data. Upon being accused of ignoring both the 1936 and the 1938 points he replied that he had not ignored either but that he gave due weight to both his line as drawn inter-

sects both the 1939 and 1937 points, and just about splits the difference between the 1936 and 1938 points, and that however interpreted, the data as taken from Hammer's calculations show a decided downward trend, whereas, if the pressure-decline method were giving the correct results the data would show a straight horizontal line instead of the sharply downward trending line. (Vol. XCI, pp. 13905-13907.)

The witness also reiterated that if the application of the pressure-decline method, as it has been applied in the Texas Panhandle Field, does not give consistent results (and it does not) that it should either be discarded entirely or interpreted in the light of the definite trends which the application of the method discloses. (Vol. XCI, p. 13912.)

Hughes further testified on cross examination (Vol. 78, pp. 11471; 11499-11508) as follows:

Q. Then you can't recall exactly what percent porosity—have you ever tried to compute the per cent porosity for individual wells of the Texas Panhandle field?

A. I must have done it at that time on those I was working on. It was necessary if I used a porosity on those wells that I was studying at that time.

Q. I thought you just told me someone else did that

A. Do you mean, did I attempt to make the laboratory determination?

Q. That is right.

A. No, I have never done that. I didn't mean to give you that impression.

* * * * *

Q. Doesn't this estimate of reserves involve the fundamentals of physics as you have applied the method here?

A. Yes, I think so.

Q. Have you any authority, any publication, any scientific journals, any text books, which would sustain you here?

A. It might be well to read what I said in my written statement.

Q. Well, I have read the written statement several times and I don't find—there is no authority cited there.

A. I have tried to describe here what I did.

Q. Of course, I am not interested in what you did right now—I know what you did, but I am interested in what authority you had for doing what you did in the field of physics.

Mr. Spencer: He is giving you his authority in his statement.

By Mr. March:

Q. What page are you referring to?

A. At the bottom of Page 5, after I described my observations I go into a little sort of a summary in which I state: "Thus I believe that for practical purposes in the Texas Panhandle permeability varies with porosity."

In the next explanation is stated: "Virgin natural open flow is an important index to original gas content because reserves are governed by pressure."

The pressure in the formation is one of the factors which you must know in order to estimate reserves and they are governed by thickness. Thickness is one of the things you must know. Porosity is another thing you must know, and when we talk about porosity in the oil and gas business we are talking about effective porosity, that is, the interconnected porosity in the formation.

Now, that statement ties in definitely to the use of physics in estimating reserves. Then the next statement is "Open flows are governed by pressure." Pressure is one of the things that influences open flow.

Referring back to the first observation on reserves, that pressure is the same in both cases.

"Open flows are governed by thickness." That ties in to direct observation in the field and it has its reasons in physics why that is true.

"Open flows are governed by permeability." Of course, back in that permeability relationship comes porosity, because you can't have permeability unless you have some effective porosity, so that the two start out from a common point. No porosity would have no permeability and then end up with a common point where under given sizes your permeability would be greater if your porosity was greater.

I think all of those statements are tied in to physics and the way I apply that to the Texas Panhandle field is then tied into my practical experience in the Panhandle which I have explained in this report.

Q. That was very interesting; however, I want to get to the point of my question. I notice here on Page 6 you say: "Permeability (for practical purposes, in the Texas Panhandle field this varies with porosity)."

Then you have at the top part of the page: "Porosity (for practical purposes, in the Texas Panhandle varies with permeability)."

Can you show me any scientific books, any scientific text books on physics which sustains any such direct relationship?

A. Well, I don't think I can show you any that states that there is a direct relationship in all cases. I don't know that I could show you a quotation that would necessarily state that there is a direct relationship in some cases. I know I could show you cases where it shows there wouldn't have to be a relationship. I have—

Q. Well, I have done a little—

Mr Spencer: Well, let him finish his answer, Mr. March.

Mr March: All right, proceed with the answer.

The Witness: I think that I have tried to explain that my practical observations in the Panhandle field allow me to conclude that there is a relationship.

By Mr. March:

Q. Is that your complete answer?

A. Well, up to this point.

Q. All right, sir. Now, I have done a little studying myself here on this subject—

Mr. Spencer: Are you testifying now?

By Mr. March:

Q. Who would you say had written the outstanding work on this subject of permeability and porosity?

A. Well, I wouldn't want to say right offhand.

Q. Do you know anybody that has written any books on it?

A. Yes, I know several. I don't know them, no.

Q. I mean, do you know who they are?

A. I know some of the names, yes.

Q. Name one.

A. This isn't a guessing contest.

Q. No, it isn't, but it seems to me, as you state, that the thing is based on some very fundamental laws of physics—the whole theory.

A. The theory is but the practical application isn't.

Q. I have in my hand here "Flow of Homogeneous Fluids" by Muskat, published in 1937—M. Muskat. Have you read that book?

A. No, I haven't.

Q. You mean you have made a careful study of this question of permeability and porosity without reading one of the leading authorities upon the subject?

A. I have made a study of it in its application to the Texas Panhandle field.

Q. Do you agree with this statement of his?

Mr. Spencer: Now, just before we do that, Mr. Examiner, there is no testimony in the record that this is a leading authority on the subject.

Mr. March: It doesn't have to be the leading authority.

Mr. Spencer: You said it was.

Mr. March: He said he didn't know whether it was a leading authority or not.

The Trial Examiner: No, you didn't ask that.

By Mr. March:

Q. Well, is he one of the leading authorities on it?

A. To be perfectly frank, I don't know.

Q. Would you agree with this statement of his on Page 12?

The Trial Examiner: Do you know the author?

The Witness: Yes, I have seen the name and I know who it is he is talking about, but I have never read the book.

By Mr. March:

Q. You know he is an outstanding authority in the field of physics, don't you—Morris Muskat?

A. I don't know for sure. I assume that he is.

Q. I see. I will ask you if you agree with this statement on Page 12. If you do you can say so. If you don't agree with it you can say so. After some discussion, it states this:

"It will be noted that since the porosity is the ratio of the volume of the unit pore to that of the unit cell (Table I), it will be independent of the radius R of the uniform spheres comprising the assemblage. However, the permeability of the array is dependent upon the actual dimensions of the pore openings and is proportional to R. Thus the porosity of an assemblage cannot alone provide an accurrate indication of its permeability. This lack of proportionality between porosity and permeability even in the ideal case is in itself sufficient to eliminate any possibility of deriving significant permeability estimates from porosity measurements."

Do you agree with that statement?

A. Well, I would have to study that.

Mr. Keffer: May I suggest, Mr. Examiner, that Mr. Hughes be given an opportunity to study this text. He is picking out a statement there and I don't know, there may be many things in there that will conflict.

Mr. March: He may have that opportunity.

Mr. Keffer: I would like to have him do that.

Mr. March: I will not ask any more questions until he has done that, but I would like to have him consider this footnote:

"Yet strangely enough, until recent years, the terms themselves were even used synonymously by some engineers, probably because the porous media with which they dealt showed in general that permeability and porosity varied in some manner."

Now, here the book is.

The Trial Examiner: Mr. Hughes, have you ever read any text books on the methods that you employed in this field?

The Witness: I don't believe that the method that I use has been described specifically as such in a text book. No, I don't think—

The Trial Examiner: It is your own method that you have worked out the mechanics of as I understand it.

The Witness: Yes, the straightforward direct application that I use here, yes.

Mr. March: There is only one other matter I want to mention along this line.

Q. I haven't been able to find, and I will be frank to admit, any scientific backup for your exhibit. There may be some and I am coming to the details of the application of the exhibit in just a minute on its merits.

I have studied and I have here the "Pennsylvania State College Mineral Industries Experiment Station, Folder No. 12," proceedings of the Third Pennsylvania Mineral Industries Conference, Petroleum and Natural Gas Section held at the Pennsylvania State College May 5th and 6th 1933 and I will let you take this and study it, too. I want to ask you if you agree with a statement in here regarding the subject.

First I want to know if you agree with the definitions and see if we have a common understanding of the definitions:

"Permeability is that property of a solid which makes possible the transport or conveyance of fluids by and through it; in other words, it is a measure of the fluid conductivity of a solid."

Mr. Spencer: Now, Mr. Examiner—

By Mr. March:

Q. Do you agree with that definition of permeability?

Mr. Spencer: Before you answer if he wants him to express his opinion on a lot of random reading from text

books here, I suggest that he designate what he wants an opinion on and give the witness a chance to look at the text book.

Mr. March: I will give him a chance.

Q. Then I want to know if you agree with this definition of porosity:

"Porosity is that property of a solid which makes possible the storage of fluids within itself; in other words, it is a measure of the fluid capacity of a solid."

Now, that is found on Page 66.

Now, near the end of this scientific publication, Page 140, we find the following statement, and I will ask you if you agree with it and you can take your time about answering it:

"The data emphasizes the fact that there is no direct and simple relation between porosity and permeability. This fact cannot be emphasized too strongly in view of the prevalent impression even among technical men and engineers that there is a relation or worse yet, that the two are equivalent. The sample of maximum porosity did not possess maximum permeability, although it can be expected that a relatively large increase in effective porosity in many cases is accompanied by an increase in permeability of considerable magnitude. However, the reverse is frequently true, also."

That is on Page 140.

Mr. Spencer: I wonder if we have a note of those.

Mr. March: That's all there is. That's all I could find.

Mr. Spencer: I am glad of that. I wouldn't want to get down to a battle of text books here.

By Mr. March:

Q. And I will still give you an opportunity if you see fit on my cross examination to cite me any authority in any text book or publication on the field of physics for your theory.

A. That is on the strict relationship between permeability and porosity.

Mr. Hughes further testified on cross examination (Vol. 85, pp. 12676-12703) with respect to the relationship of porosity to permeability, as follows:

Cross Examination (Continued).

By Mr. March:

Q. Mr. Hughes, you have had an opportunity to study those two books I gave you. One was Muskat's Flow of Homogeneous Fluids and I asked you if you agreed with the statement I read into the record from Page 12 of that book. I will again ask you that question.

Mr. Spencer: Mr. March, do you think we should have the statement read into the record again at this point?

Mr. March: The statement was read into the record on Page 11504 and 11505 of the transcript. I think that will suffice, but he can read it into the record again if he so desires.

Mr. Spencer: I am not insisting upon it if it is sufficiently identified.

Mr. March: I have the part that was read into the record right here.

The Witness: I don't remember exactly the portion that was read into the record.

By Mr. March:

Q. Do you have Page 12 there?

A. Yes.

Q. You might read here, starting with "It will be noted • • •" the top paragraph on Page 12, and the footnate 2 on page 12.

A. "It will be noted that since the porosity is the ratio of the volume of the unit pore to that of the unit cell • • • it will be independent of the radius R of the uniform spheres comprising the assemblage. However, the permeability of the array is dependent upon the actual dimensions of the pore openings and is proportional to R^2."

Wait a minute. That has a 2. It looks like R^2. The 2 refers to the footnote. That should be "proportional to R."

"Thus the porosity of an assemblage cannot alone provide an accurate indication of its permeability. This lack of proportionality between porosity and permeability, even in the ideal case, is in itself sufficient to eliminate any possibility of deriving significant permeability estimates from porosity measurements."

I want to correct myself again. There is another "2" after that, so I am quite sure back up there the "R" should have read "R^2."

Q. You forgot to read footnote 2.

A. Yes. The footnote says: "Yet strangely enough until recent years the terms themselves were even used synonymously by some engineers, probably because the porous media with which they dealt showed in general that permeability and porosity varied in the same manner."

May I make some comment here?

Q. First I want to know if you agree with that statement?

A. Yes, I agree quite definitely with this statement and I always have recognized that porosity and permeability did not need to vary together and this book is a lengthy treatise that shows the mathematics of why they do not need to, although all through the book he recognizes the relationship—a relationship. That relationship starts from the very fact that in order to have permeability you must have some porosity and coming back to this sentence in the first paragraph I just read where he says: "Thus the porosity of an assemblage cannot alone provide an accurate indication of its permeability" shows what I mean. These authorities definitely recognize the relationship but approve very distinctly and to great extent with very advance mathematics why that is not true, but the significance of what these theoretical treatises have to do with the actual field experience and field practice is brought out, I think, in this footnote where he says: "Yet strangely enough, until recent years, the terms themselves were even used synonymously by some engineers." At that point we have a highly theoretical—the author of a very highly theoretical treatise on the subject, you might say, is not condemning them for using the term "synonymously," but pointed out they

did use the term "synonymously;" that is, the terms "porosity" and "permeability," and I want to point out we have not done that. We have not used the term "synonymously."

He also points out why they were doing that, because in the very same sentence he says: " * * * probably because the porous media with which they dealt showed in general that permeability and porosity varied in the same manner."

My interpretation of that statement is that he definitely recognizes that these engineers out on the job and dealing with actual practical examples had found that the "porous media"—I am using his very words—"with which they dealt, showed in general that permeability and porosity varied in the same manner."

At that point my experience in the Panhandle field fits in with his statement; however, I want to make it very definite here again that this has to do with the very strictest interpretation of how porosity and permeability go along together.

Now, I haven't made any claim that in my treatment of reserves in the Panhandle field that porosity and permeability do have to go along on a very hair-splitting straight line relationship. In fact, my zone map is not a map of permeability. My zone map is a map of open flow. A relationship is constantly between open flow and reserves and not between permeability and porosity. The relationship between permeability and porosity is only one of the factors that enters into what open flow really is.

My relationship, and it is shown on my zone map, is the relationship between open flow and reserves in place.

Q. Now, I asked you in regard to the other book you have there, the publication, referring to Page 6—

A. May I point out one more thing?

Q. Surely. Go right ahead.

A. I have one more citation—

Q. Wait just a moment. Is that citation from Muskat's book on "Flow of Homogeneous Fluids"?

A. Yes, sir.

Q. It is from this book you have here?

A. Yes. By the way, I didn't make these marks on this book. I notice there is a warning in the front of this book. It says: "Whoever writes in, tears or injures in any way a book belonging to the Denver Public Library may be punished by fine from $2 to $25," and I definitely didn't make the marks on this book.

Q. Confidentially, I didn't either.

The Trial Examiner: Will you serve a copy of this page to the library when it is returned?

The Witness: On Page 80 of Muskat's book in the middle of the paragrapl. there in the middle of the page he says: "While it appears probable that the porosity of a given heterogeneous sand will be the primary property determining the final value of the permeability of the given assembly of sand grains, it is nevertheless not unlikely that the porosity will still not give a completely sufficient specification * * *" my interpretation is that he definitely recognizes a relationship by that "* * *the porosity will still not give a completely sufficient specification * * *" emphasis on the "completely."

That ties in with the bottom of Page 12, with the note on the bottom of Page 12.

By Mr. March:

Q. I will ask you to see anywhere it shows the direct relationship between permeability and porosity.

A. I don't say that it does. I don't demand an absolutely direct one. As I explained before, on reserves in the Texas Panhandle field, it has to do with the relationship between open flows and reserves in place, and the relation between porosity and permeability is only one of the factors that governs open flow. Thickness is another factor. I think I have tried to explain in our experience in the Panhandle, that whatever the permeability might be, if you have a big well, of course, you have a thick pay or a good permeable porous zone.

Now, if you had a well that had high permeability locally but did not have a great amount of void spaces which would be definitely related to thickness and porosity, then

that open flow would not be sustained. The fact is that these large wells, the average large wells in the Panhandle field, do have enough porosity and thickness back of them in order to sustain, and if you had the reverse in that case you would have a freak well that would either be discounted in its apparent open flow or would be discounted in the size of the area that is involved, so again I want to make it very clear that my relationship is on open flow and reserves.

Q. All right, let's come to the next book there, your "Pennsylvania State College, Mineral Industries Experiment Station, Folder No. 12." First I will ask you in regard to the definition of permeability and porosity. I think it is on Page 66 there.

A. There is a definition, yes, on Page 66 of each term.

Q. It is referred to here in the record on Page 11507.

A. Do I agree to those definitions?

Q. Yes. There is also reference to it in the transcript on Page 11506. Do you agree with those definitions of permeability and porosity?

A. I might read those definitions here again:

"Permeability is that property of a solid which makes possible the transport or conveyance of fluids by and through it; in other words, it is a measure of the fluid conductivity of a solid."

"Porosity is that property of a solid which makes possible the storage of fluids within itself; in other words, it is a measure of the fluid capacity of a solid."

Of course, I agree with those definitions in a general way; however, the permeability is dependent upon the effective porosity rather than on the absolute porosity, because in order to have any permeability at all we must have an inter-connection of porosity; that is, the porous spaces must be connected in order to allow the flow through the solid, again showing quite definitely that it is related.

Q. The next one I believe is on Page 140.

A. The next sentence right after the paragraph on porosity states: "The only simple relation between the two is a qualitative one, namely, a solid is permeable by virtue of its porosity."

That is just what I stated in my own words.

Q. Turn to Page 140 and read that paragraph I asked you if you agreed with, beginning with "The data emphasizes the fact * * *".

A. Page 140?

Q. That's right.

A. Is that another one you read into the record?

Q. That is right. That is the main one. It starts with "The data emphasizes the fact * * *" beginning there on Page 140.

A. Well, that very first sentence says: "The data emphasizes the fact that there is no direct and simple relation between porosity and permeability."

I would like to indicate the emphasis on direct and simple relationship. Again that indicates that there is a relation. Now, quoting from that point, do you want me to read the rest of the quotation?

Q. Go ahead.

A. "This fact cannot be emphasized too strongly in view of the prevalent impression even among technical men and engineers that there is a relation, or worse yet, that the two are equivalent."

Of course, I haven't made any contention that the two are equivalent. It states further: "The sample of maximum porosity did not possess maximum permeability, although it can be expected that a relatively large increase in effective porosity in many cases is accompanied by an increase in permeability of considerable magnitude. However, the reverse is frequently true, also."

Again that shows quite definitely the thing that I have observed in the Panhandle field that can quite definitely exist even though their mathematics shows it does not need to exist. I agree right along it does not need to exist and there would be many places where it wouldn't.

Q. I believe that is all of the quotations isn't it?

A. Is that all you wanted me to read?

Q. Yes. Just a minute. You can read any other portions you see fit.

A. I would like to mention one or two more from this

bulletin. I would like to mention, too, that this bulletin from the Pennsylvania State College and a great deal of the other work that has been done in recent years on permeability and porosity has to do with the problem of secondary recovery of oil from old abandoned oil fields where the permeability relationship is much more amplified with respect to a viscous fluid like oil than it is in a gas field. It is just obvious that the permeability has more to do with a viscous substance like oil, a liquid, than it would on gas. This bulletin from the Pensylvania State College was dated May 1939.

On Page 93 of the Pennsylvania State College bulletin—just a moment. Is that the same article?

A. Yes, it is the same treatise, Bulletin 12.

Q. All right, go ahead.

A. Near the bottom of the page it says: "The results seemed to indicate that permeability was related to porosity in grain size, and a plot of the permeability versus porosity defined a curve. From a knowledge of results in the field the conclusion was drawn that in the Bradford and Richburg areas porosity is a criterion of permeability."

These conclusions—you want to see if I am reading this word-for-word, do you?

Q. I just want to see what page you were reading from.

A. "These conclusions are concurred in by Barb * * * and Barb and Branson * * * in presenting an equation defining the relation between these factors for the Bradford sand of average grain size as a result of many tests."

I think it is evident that they recognized a relationship.

In the middle of Page 94 they state: "There seemed to be a parobolic relation between permeability and porosity."

In that case the word "parobolic" refers only to the shape of the curve which is a curve relationship as stated in the citation that I just read to you previously.

On Page 170 of the same bulletin under "Discussion," Mr. Pierce—

Q. Is that a part of the transcript you are reading?

A. It is under "Discussion."

Q. This isn't a part of the article of the scientific studies I quoted from, is it?

A. It is a part of the bulletin quite definitely. It is a discussion by the various members in session.

Q. Go right ahead.

A. It is published here as part of this bulletin we are talking about. Mr. Pierce says: "I have long been a radical on condemning engineers who relate porosity to permeability only. Now I am in the position of coming back to their aid. I feel that Messrs. Fancher and Lewis go too far." They were the authors of this treatise preceding these pages.

It states further: "It is not true that there is no relationship with a definite substance there is a relationship."

Now, again I want to point out the fact that those men in dealing with the highly mathematical reasons why there would not need to always be a relationship have found in their contact with practical engineers and geologists with conditions out in the field that those engineers have been realizing a definite relationship for a long time. It is quite evident that what he says is significant in what I have done.

He says: "With a definite substance there is a definite relationship." Just a minute. I want to correct that It says: "With a definite substance there is a relationship." That is exactly what I have found in the Panhandle, but again I want to point out that relationship is not the sole governing factor that entered into my observation of a definite relationship between open flow and reserves. This thing we are talking about in these bulletins is the very very strict relationship between porosity and permeability.

Now, there is another citation—

Mr. Keffer: May I ask a question here, Mr. March?

Mr. March: Yes.

Mr. Keffer: Do you know that the Mr. Pierce you quoted from there is Homer Pierce or H. R. Pierce from the Bureau of Mines? If you don't know, that is all right.

The Witness: I couldn't tell you definitely.

Mr. Keffer: All right.

The Witness: I am trying to see if these men who took part in this discussion have their relationship set forth, but I don't see it here.

Another citation is on Page 171 in this "Discussion." It is by Mr. Hogg.

By Mr. March:

Q. Is that a part of the transcript?

A. Yes.

Q. What page is it on?

A. Page 171. It states: "With reference to Mr. Pierce's remarks, it is possible that there is more of a relationship between permeability and effective porosity than between permeability and absolute porosity."

Of course, my explanation a moment ago would definitely indicate that I agree with that, that the relationship of the—at all times when we are talking about the porosity of a reservoir, we must talk about the effective porosity, because if there is a part of the porosity that is not effectively interconnected with the reservoir or whatever might be in it would never be an effective part of the reserves that we would be talking about; that is, if it were sealed off it wouldn't be a part of the reserve that we would want to be discussing.

On the same page, Doctor Fancher in this same discussion and one of the authors of the paper, says: "Permeability is some function of porosity providing we consider other factors. High porosity does not always mean high permeability. There is in general an increase of permeability with increase in porosity but the relationship is perhaps an exponential and complex function of other variables as well as porosity."

There again he recognizes relationship between permeability and porosity and again I want to point out that this relationship has been recognized by engineers who are out on the job in the field and his technical discussion recognized that fact, that engineers have noted the relationship; and as I pointed out, Muskat, you might say, took the engineers to task for observing the relationship in the media they were dealing with but for using the term "synonymously."

Q. Nobody is going to deny there is a relationship but I challenge you to show *me* anywhere in this book where there is a direct relationship.

A. I told you a while ago I didn't say that there was and I do not demand from my treatment of what I am doing with open flow as related to reserves of gas in the Panhandle field that the relationship there is dependent upon porosity and permeability only in part. Therefore, that relationship would not have to be a straight line, definite hair-splitting relationship. I am dealing with wells in the field, with averages of wells of the same size and type where the thicknesses and these permeability relationships tend to average out.

We even noticed the samples that were employed in detail from the one well, the Shell No. 3 Haggard, showed that even within that one hole that the permeabilities varied so that we are dealing with the open flows of wells and back down in the formations from which those open flows are controlled we have averages and we have the ranges from low to high both in porosity and permeability.

Mr. Keffer: From the same well?

The Witness: From the same well.

By Mr. March:

Q. I will challenge you to present any scientific proof from published scientific journals where the open flow indicates gas in place.

A. I will be glad to do that. I want to refer you right at that point to the report of investigation 3313 of the United States Bureau of Mines. The title of that bulletin is "Extent and Availability of Natural Gas Reserves in Michigan 'Stray' Sandstone, Horizon of Central Michigan."

This report is by E. L. Rawlins and M. A. Schellhardt. Now, you challenge me to show you where in the text there is a relationship between open flow—

Q. Direct relationship between open flow and gas in place.

A. We have left the porosity and permeability relationship and have gone to the very thing I am talking about in the Panhandle field of Texas.

Q. That is right. Proceed.

A. In this report they make an estimate of gas reserves in the Michigan stray sandstone zone horizons of Central Michigan. They make these estimates on the porosity thickness method. Now, in order to make such estimates you must arrive at your porosity. I will come to that in a little bit here. You must also have thickness.

On Page 11, the third paragraph—I am reading from this report—it states: "Two principal methods of analysis have been used in this report to determine the average productive thickness throughout a field. The first method is based upon an average of the interpreted productive thicknesses of the individual wells in the field being studied.

"The second method is based upon an interpretation of average open flow volume per foot of productive thickness. Ordinarily, for thicker productive lenses than occur in Central Michigan a study would be made of the open flow volume per square foot of productive formation exposed in the drill hole, but for the comparatively thin productive sandstone lenses in Central Michigan fields it is believed that an interpretation based on the open flow volume per foot of productive thickness is satisfactory."

I want to explain in detail just what that means. It means quite definitely that in order to estimate reserves in the manner in which he did, using the porosity thickness method, in order to arrive at the reserves he must have a porosity figure and he must also have a thickness figure.

Now, in this explanation it shows quite obviously that he arrived at thicknesses in individual wells that were studied and in some wells where the thicknesses were unknown to him he used the open flow as an indicator of the thickness.

Now, in order to have a porosity to go along with that open flow or with that thickness, I want to quote how he found the porosity. I am reading now the paragraph under "Porosity" near the top of Page 8 in this report:

"Cores have not been obtained from any wells in the Clare, Hinton-Millbrook-Belvidere, Home-Richland-Day or Ferris-Crystal areas, and consequently porosity tests applicable to these fields have not been made. A porosity test on a sample from one well in the Vernon field indicated a porosity of approximately 19.5 per cent. Samples of

the productive formations from several wells in the Austin field were tested for porosity in a Chicago laboratory and results averaged about 17 per cent. A sample obtained from what seemed to be a very porous streak in one of the wells in the Austin field and tested at the Petroleum Experiment Station, Bureau of Mines, Bartlesville, Oklahoma, had a porosity of approximately 24 per cent. Reports on samples obtained in the Broomfield field indicated a porosity ranging from 18 to 20 per cent. A consideration of these data indicates that it is reasonable to assume a porosity of 20 per cent in estimating gas resources in the higher parts of the structures and 18 per cent in computing probable reserves farther down the structure."

At that point I want to point out that he has an estimate of porosity. In order to go along with an estimate of porosity in an area where he did not know the thickness of the sand he let the open flow be his guide to what that thickness was and it is explained quite definitely in the first quotation that I read.

Now, the only difference between what he did and what I do is that I don't set up an average porosity to go along with my open flow. If I wanted to follow specifically what he has done, I could go along with each well with an assumed porosity of 20 per cent, say, and by means of the open flow let the open flow give me an estimated thickness and at that point I could use porosity and thickness and it would show the mathematics of the computation arriving at the reserve.

The only difference between what he says and what I do is that I let my open flow be a guide to both porosity and thickness. I want to point out again what he did was, he had an assumed porosity and with that assumed porosity he let his open flow be a definite guide as to thickness.

Right in connection with that, several years ago while Mr. Rawlins was still with the Bureau of Mines and before this report was published—the date of this report is July 1936—at the time I was working for the Cities Service in connection with the Topeka case—as I remember it was in the spring of 1935. I remember I told you the other day the case was in 1935—I had a long conference with Mr. Rawlins who was still then with the Bureau of Mines and located at Bartlesville, Oklahoma.

I explained in detail just what I was doing in the Panhandle field, how I had arrived at the fact there was a relationship between open flow and reserves in place. As I discussed what I was doing in the Panhandle, he very—

Mr. March: Just a minute. I object to that statement for this reason, because my witness wasn't permitted to say what the Phillips Petroleum Company had discovered about the known relation between porosity and permeability. Mr. Hammer was on the stand and I asked him as to the Phillips Petroleum Company showing there was no relationship between permeability and porosity—

Mr. Keffer: Just a moment, Mr. March. We will grant the soundness of the objection, Mr. Examiner.

The Trial Examiner: Very well.

Mr. Keffer: You need not say any more, Mr. March. We have granted it.

Mr. March: I would rather let my man go on.

Q. Is that all of the statement you have about that report?

Mr. Spencer: You interrupted the train of thought of the witness.

Mr. March: Just skip the Rawlins conversation.

Q. Is there any other statement you wish to make? If there is, we will be glad to have it.

A. Skipping the discussion, I can go along and quite definitely state what I have done in the Texas Panhandle field is definitely what he did in the areas of the Michigan field where he had no thicknesses and where he hadn't an assumed porosity, but he let his open flow be the definite index as to the amount of gas in place.

The only difference was, he came around and carried through the mathematics after letting the open flow give him an estimate of thickness, but the result is the same. Had he set up his relationship he could have gone directly by means of a factor from open flow to reserves in place Just what that factor could have been, I do not know. It most certainly would not have been the same factor that I used in the Texas Panhandle field. I wouldn't expect the

factor I used in the Panhandle field to be the same in another field. That factor would have to be determined; however, I want to point out that he could have definitely gone from open flow by means of the factor to reserve content per acre in place.

Q. But he didn't?

A. I say that the only difference—the result is that relationship—

Q. But he didn't, I said.

A. I could answer that better if I could refer to my conversation with him.

Q. I see.

A. The result is, he did do it. For instance, I could point it out very distinctly that the way I applied a direct relationship between open flow and reserves in place in the Panhandle field at a given well with this relationship between open flow, I could assume porosity and I could calculate by means of that porosity what the necessary thickness would have been, and my answer would be the same as the answer that I do get without calculating it. That is what I am trying to show you, that the only difference between what I did and what he did is, he has recognized this direct relationship between open flow and reserves in place, but he merely went through the mathematics of showing what thickness was necessary in order to accommodate that given relationship. It was an assumed proposition all the way through, based upon the definite recognition of the relationship between open flow and reserves in place.

Q. The field you referred to is located in Michigan?

A. I stated the title of the bulletin.

Q. Those sands are pretty well uniform, aren't they, as to content?

A. No, they are not. I think you could gather from the paragraph that I read that they were not.

Q. You made some very interesting statements here, Mr. Hughes. I believe you stated here that you arrived at the porosity and pay thickness of the Texas Panhandle field by the open flow method of estimating reserves.

A. Would you have that read for me?

Q. I understand the effect of it was—

A. I would like to have it read.

Q. I will ask you the question directly. Did you determine the pay thickness of the Texas Panhandle field?

Mr. Spencer: In connection with the preparation of this exhibit?

Mr. March: In connection with the preparation of this exhibit.

The Witness: I have explained at length what I did, that I arrived at thicknesses and porosities in a group of wells from which point with an observed relationship between open flow and reserves I went immediately from that to the field as a whole with that relationship of open flow to reserves.

By Mr. March:

Q. I want to ask you if you did arrive at the pay thickness for the entire field?

A. No, definitely not. I think that has been clear in the record.

Q. And in arriving at the pay thicknesses in those few wells which you didn't have the names of, I believe you used the same method that Mr. Rawlins uses here in the Michigan field, or did you?

A. May I have that bulletin again?

Q. Certainly.

A. I told you what he does—

The Trial Examiner: We have spent considerable time on that, Mr. March, explaining the difference between what he did and what Mr. Rawlins did.

Mr. March: I just want to ask a few questions in regard to that, Mr. Examiner. If in those early wells he did arrive at the pay thicknesses in the manner Mr. Rawlins did, that is something different than what he did at the beginning, because from what I understand, he had samples to ascertain the pay thicknesses of those early wells he examined. It makes a big difference. I want to just clear that point up.

Mr. Keffer: Of course he said quite definitely, Mr. March, as I understood him, at least, that he didn't apply open flows for the determination of sand thicknesses.

Mr. March: If he will make that statement in regard to the early wells, that is all right.

The Witness: Let me make a statement—

By Mr. March:

Q. Did you use the method Mr. Rawlins has outlined here in arriving at the pay thicknesses of the few early wells?

A. You mean by that method in which he

Q. Open flow.

A. Quite definitely, no.

I want to point out what I did as compared with what he did. I observed the thickness and porosity on a group of wells that started me out on my relationship between the open flows of those wells and the reserves.

Now, I want to point out that that is also what Mr. Rawlins did in Michigan. I have read that quite distinctly in the first quotation from Mr. Rawlins where he says

Mr. Spencer: I don't think there is any necessity of repeating it, Mr. Hughes.

The Witness: All right.

By Mr. March:

Q. Did you know that in the Texas Panhandle field that 5 million cubic feet—strike that.

Did you know that in the Texas Panhandle field five feet of pay may have 10 million cubic feet of gas and 10 feet of pay may have 3 million feet of gas?

A. I haven't in mind at the moment a specific case proving that point, but I wouldn't be surprised at all. I wouldn't be surprised if the contrary were true.

Q. Then your open flow doesn't indicate pay thickness, does it?

A. The pay thickness is one of the things that governs open flow. The other is the porosity.

Q. Yes.

A. And permeability. If you have greater volume from the lesser thickness, naturally you have greater porosity and permeability with that lesser thickness. That is just obvious. It works out that way quite definitely in the Texas Panhandle field.

Q. If your pay thickness had different content, how in the world can you gather anything about reserves in the Texas Panhandle field?

A. Well, I have explained how I arrive at it. Now, at that point it is obvious that pay thickness is not the sole governing factor of reserves and it is not the sole governing factor on open flow. It is only one of the factors.

Q. Oh, yes, there is one other question I want to ask you in regard to this Pennsylvania bulletin. You are aware of the fact that in this Pennsylvania State bulletin these two individuals who wrote this article examined some three or four hundred cores to come to their conclusions?

A. They have quite a list of determinations in the bulletin. Whether they actually did the work or not, I am not in a position to say. There is a list of quite a few determinations of core samples. Of course those core samples are very small and they represent only a few inches of the formation and the core which is used—the actual piece of the formation which is about as big as your thumb or a little larger, that actually goes into the determination of permeability, is not the identical piece of the formation from which the porosity is tested.

Undoubtedly it is from the same general portion of the core. That, of course, is as near the same as they could get it, I presume.

Q. These analyses of cores, three hundred and some odd here, of the authors of the Pennsylvania State bulletin, are similar to that of the Shell Petroleum Company that we discussed, aren't they?

A. Well, they are similar in that they are determinations of porosity and permeability. I have made no attempt to plot those curves or those relationships into a curve.

Q. You are aware, though, are you not, that the conclusions on Page 140 are based upon that comprehensive study on those cores?

A. Let me see the conclusions on Page 140.

Q. You just read them.

A. I don't think those conclusions refer to all of the determinations. They might. I wouldn't want to make a point of that but I want to refer you to the situation that I quoted in which the results of those permeability-porosity *testes* showed that there was a curve relationship. I think I read the citation in which that was stated.

Q. Yes. Now, do you have any other authority, do you think, to support that open flow indicates gas in place?

A. Well, I wanted to clear up one thing just a moment there. You said that I have read those bulletins. I did not read either one of those books completely word for word: I have not read those.

Q. Did you read the Pennsylvania State bulletin?

A. I skimmed through it but I don't want it left in the record that I read and made a complete study of that bulletin, word for word.

Mr. Hughes further testified on cross examination (Vol. 79, pp. 11650-11653) as follows:

Q. The permeability has a lot to do with the reservoir condition, doesn't it?

A. The reservoir—the porosity is one of the definite factors that determines permeability. The porosity and thickness governs the reserves.

Q. Have you ever made a study to ascertain what the thickness is in those two wells?

A. No, I haven't.

Q. How do you know one has a higher thickness than the other?

A. I think I explained in the beginning that my observation was that open flow was dependent upon thickness, and permeability, which was tied in definitely with porosity.

Now, from that statement I have explained—if I haven't explained it clearly I want to make it clear now, that the reason I went from that observation to the rest of the field from the area where I knew that relation was—I went to the rest of the field on a direct relationship by means of open flow—that it was largely because I didn't have these other figures on those other areas of the field.

"These other figures," by that I refer to the thicknesses. As I went from my known areas to the unknown areas I let my open flow be my measure, my index, which covers both thickness and porosity, that is exactly what I did, so except just for curiosity I would have no reason to examine those particular wells as to what thickness the log might have shown or whether it showed any thickness or whether it was a reliable record or what.

Q. So you used this method of estimating reserves be-

cause you didn't have reliable data to estimate the reserves on the pay thickness and the porosity method?

A. If I knew specifically what the thickness was in every tract in that field and knew what the porosity was on every tract in that field, I wouldn't need to use any other method.

Q. Isn't it true the reason you can't apply the porosity thickness method is because you can't secure accurate thickness and accurate porosity for the entire field?

A. I won't make that broad a statement. I will tell you what I did—

Q. Yes.

A. I realized that I had some test areas in which I felt that I knew what the thicknesses and the porosities were, and after finding that they were related to open flows, then whether I made a detailed search to prove that the thicknesses were available or not, I went on to the unknown areas by means of open flows.

The fact that I have done that doesn't necessarily prove that what you said a moment ago was true, that is, that you don't have enough thicknesses. I found at that time that it was very difficult to know in many of the other instances what the thicknesses were and what the porosities were, and it was a matter of convenience and necessity that allowed me to conclude that my relationship was true and to go ahead from that, from the known into the unknown by means of open flow.

Q. Of course, you can't name me a single well which you conducted those experiments on?

A. I told you yesterday that I did not have a list of those wells, but the observations were definitely made. They were made by me a number of years ago.

Q. I have made some sort of a study of some pay thicknesses which have been prepared by some geologists. Have you examined those pay thicknesses made by those geologists?

A. I have discussed them at length.

Q. Have you examined the pay thicknesses?

A. I heard you read a lot of them. I have seen a list of them but I haven't made an attempt to check them, if that is what you mean.

Q. Have you—if you checked one of those and found you had a 50 million open flow well with a lower pay thickness than a 25 million open flow well, that would indicate to you in the case of the two particular wells there was no direct relation between the pay thickness and the open flow?

A. It would indicate to me the well that had the same pay thickness with a little larger open flow would have more porosity.

Q. That is the only conclusion you would want to draw?

A. That is the pertinent conclusion.

Q. If the well had more than a 20 per cent porosity, an open flow well, what would you say?

A. I would say it had more than a 20 per cent porosity.

Q. Do you know of any laboratory test by which you can determine the porosities of gas wells in the Texas Panhandle field?

A. I think we discussed that at length yesterday.

Q. You don't know of any?

A. Yes, I described some. You can read in the record what I said about that yesterday.

Q. I asked you to give me a single well in the Texas Panhandle field where there were laboratory tests on the samples taken from that well where the porosities had been determined by anybody.

A. You mean the complete porosities?

Q. I mean the porosities of the pay formations.

A. No; I agreed with you I didn't know of any cases of that sort.

* * * * *

Mr. Hughes further testified on cross examination (Vol. 80, pp. 11849-11850) as follows:

Q. I come next to the next Shamrock well, it is the Garland-McKee well, located in Section 399, Block 44—the same block as the other—and H & T C Survey, with an open flow of—my record shows 160 million but I don't have those records here, and your record shows as I see it, 155 million.

A. There is a well. I have a well in that section.

Q. 155 million?

A. 155 million, yes, sir.

Q. Now, Mr. Hughes, I want to know if in making up your averages for these zones you included that Shamrock well in the average.

A. Well, what is the date of the completion?

Q. The date of completion of that well is 5-13-38.

A. 5-13-38?

Q. Yes, sir.

A. I wouldn't definitely know without the—the same applies to that that I made on the wells just before. I am inclined now as I look back and reconstruct what went into the picture that I have painted on those zones—I doubt very much if I would have used it according to what I know about those wells today, I know that I wouldn't have used them if I had known about them then what I know about them today.

Q. What in the world did you put that open flow up there on your map as being your open flow for, then?

A. I explained that, too.

Q. Did you correct that back to virgin open flow conditions?

A. I doubt it.

And again, (pp. 11869-11870, Vol. 80),

Q. I notice here in these two examples which you have set forth you have used in both cases a 20 per cent porosity.

A. Yes, sir, in the example.

Q. I notice that in one case you use a 40 foot pay thickness and in the other case a 20 foot pay thickness, is that correct? For the large well of 10 million open flow you used a 40 foot pay thickness and for the small well of 10 million open flow you used a 20 foot pay thickness, is that correct?

A. Yes. You mentioned the small wells. The smallest well is 5 million, isn't it?

Q. Yes. Mr. Hughes, I thought you told me when we approached this the other day you couldn't recall what pay thickness you used in your original calculations.

A. I don't. That is an example. Those are examples of what I was talking about.

Q. This is not any particular well?

A. Absolutely not.

Q. You still don't know whether you used a 20 per cent porosity and a 70 foot pay thickness?

A. It shows there I didn't use a 70 foot pay thickness.

Q. Against what size well would you have used it?

A. It depends. I used what I observed at the time.

Q. Do you mean to say that these examples are actual wells?

A. No. I thought I made that plain. In case they are, I didn't intend to show that they were. They were given as examples to show how the formula—it is shown in Example 1 and it is shown in Example 2.

Q. Now, then, you cannot tell me the pay thickness which you used?

A. No, and I told you that the other day many times on the individual wells, but I did it and I did it on a number of wells and I convinced myself I was doing a right and reasonable thing.

Q. Can you show me any place in the Panhandle field where you have two wells right close together where the smaller well has half the pay thickness of the larger well?

A. I think I could but right offhand I don't know. It might work out that way. It wouldn't have to.

And again, (pp. 11878-11879, Vol. 80),

Q. Yes, but I want to know the answer to a very simple question. I want to know why you haven't tried to apply the porosity thickness method to the entire field in arriving at your factor.

A. You know that as well as I do and it has been stated there are many many wells in the field that you can't find out what the thicknesses were. The records were poor and they were not carefully watched, and a lot of wells were drilled by operators that weren't particularly interested in trying to get details of that nature. There are many many wells in the field that I wouldn't attempt to tell what the thickness was, however, I do know what their volume open flow was and I have explained how I have interpreted those open flows and I show what interpretation caused me to arrive at that.

Q. We are at the first step now we take in getting your 1-1 factor.

A. Yes.

Q. You arrive at the 1-1 factor by using the porosity thickness method on some wells on some parts of the field which wells you cannot tell me specifically?

A. That is right.

Q. Or the pay thickness or porosity? You cannot tell me specifically?

A. That is right.

And again, (pp. 11895-11905, Vol. 80.),

Q. Here is my question: It is very simple. Did you at any time in the preparation of these two exhibits here apply the pressure decline method to the whole field in trying to arrive at your factor? You can answer that question very simply.

A. I have told you that I have been applying the pressure decline method to the entire field for a number of years.

Q. In the preparation of this exhibit?

A. Well, naturally it was prior to the exhibit, because I have been doing it for a number of years.

Q. Well, what was the pressure that you used—the average pressure that you used?

A. Do you want to know from me if I have gone through the arithmetic of taking the production from the Panhandle field at a given date and taken the weighted average pressure of the Panhandle field at that same date and make the bald application of the pressure decline method? Is that your question?

Q. Yes, without inserting a per acre content before you start.

A. Yes, I have done that on a number of occasions.

Q. Let's do that right now, using your own production figures, assuming that they are right. All right, in Exhibit 212 you have a production figure as of August 1939, the total withdrawals as I see it, of 7,485,066,520 Mcf.

The Trial Examiner: You are talking about Exhibit 211?

Mr. March: Exhibit 211.

You have that as your withdrawal figure, do you not, at 16.4 pounds?

The Witness: That's right.

Call it 7½ trillion in round numbers.

Mr. Lange: Page 15, Mr. Examiner.

The Witness: Call it 7½ trillion approximately. If I am going to identify it—do anything with a slide rule, that's about as close as it would be on the slide rule.

By Mr. March:

Q. All right, sir. Then, next, I believe the virgin pressure is 430 pounds. We can assume that, can't we?

A. Yes.

Q. All right, sir. Now, the Texas Railroad Commission weighted areal pressure for the entire field for the summer of 1939 is, according to my figure taken from the Railroad Commission, 323.7 pounds.

A. That sounds about right. I have it here. I think that is it—323.72, July, 1939.

Q. All right, we'll take that as our average weighted areal pressure. All right, you subtract, do you not to get your pounds lost—430 minus 323.7?

A. Yes, that's right.

Q. All right, and what do you get?

A. 106.28 pounds.

Q. 106.3 pounds?

A. That's close enough.

Q. You divide, do you not, your 7½ trillion by this 106.3 pounds to get your per pound drop?

A. You can, yes.

Q. Well, do that, will you?

Mr. Keffer: May I have an understanding at this time with Mr. March that when he goes through this complicated computation that you will give the witness an opportunity to explain in connection with it why this sort of computation cannot give the right answer, otherwise, I am going to object.

Mr. March: I will give him an opportunity to make a lecture on it.

Q. What answer do you get?

A. How's that?

Q. What answer do you get?

A. You are trying to get the production per pound drop?

Q. Yes.

A. That is 7½ divided by 106.3. That gives you about 70½ billion per pound drop.

Q. Yes.

A. Yes—70.5 billion in round numbers. I am reading from this.

Q. Now, right there, where is your similar figure that you calculated out here by your method of open flow, indicating gas in place?

A. My figure doesn't indicate gas in place. My figure indicates original reserve.

Q. All right, you don't have a per pound drop figure and you don't have those figures in existence, is that right?

A. My estimate of gas in place would be the difference between that original at this stage—

Q. All right, now, the production per pound drop—now, we'll calculate the remaining reserves to zero pounds wellhead and is it not correct that you multiply your 323.7 to your average pressure.

A. It just so happens in the Panhandle it is not correct to do what you are doing, but we will do it for arithmetic.

Q. You said you checked your method against the pressure decline method. I am not saying this is not an application of the pressure decline method in the Panhandle field.

A. That will be covered in my speech.

Q. All right, I want to give you the opportunity to make that speech.

All right, you multiply your weighted average pressures by your per pound drop to get your remaining reserves, do you not?

A. I am following your instructions.

Q. Well, don't you do that?

A. Well, we are doing it in this arithmetic, this arithmetic we are doing now.

Q. Isn't this the application of the pressure decline method to the Panhandle field of Texas?

A. It might be your application, but it certainly is not mine and I can give you many reasons why after a while, and I know what the answers are going to be.

Q. What's it going to be—about 30 trillion?

A. I have done it many times. I have been doing it for years.

Q. All right, now tell me this: Just wherein did the way that you apply the pressure decline method in checking your factor differ from the way that we are applying it?

A. Apparently I didn't make it clear in my explanation but the explanation did make it clear. I made it as clear as I could.

Q. The only difference is you started out with your per acre content.

A. Pardon me.

Q. The only difference being that you started out with your per acre content?

A. Yes, I started out with what I thought to be the per acre content and it turned out that in applying it in that method the application of the pressure decline method showed that it was a reasonably correct figure, too, but this is not going to do it.

Q. All right, then I will let you tell me when we get through here just how you did it, just how it is different from this and just why the difference.

Next you multiply your weighted average pressure by your per pound—

A. You want me to multiply 70.5 billion by 324 pounds?

Q. Yes—323.7 pounds.

A. That gives you a product of 22.8.

Q. 22.8. All right, sir, now that is on a 16.4 pounds per square inch basis, isn't it?

A. How's that?

Q. That is on a 16.4 pounds pressure base, isn't it? That answer is on a 16.4 pound pressure base?

A. Yes, it is, because the pressure base of the figures that we started out—

Q. All right, now, you convert that over to a 14.65 pound pressure base.

A. You want me to multiply 22.8 by 1.11 and—call it 1.12—that is the conversion factor to change gas on the basis of 16.4 to 14.65 base. 22.8 times 1.12 becomes approximately 24.15.

Q. I get 25½.

A. Wait a minute.

Q. I didn't get it, I'll confess that.

A. I am used to using my little slide rule that has half the number of divisions on it.

Q. I get 25½ trillion.

A. No, it wouldn't be quite 25½—22.8 times 1.12 gives you 25.3, approximately.

Q. All right, sir, now we have lost this 7½ trillion by withdrawals according to your estimate of withdrawals. I want you now to convert that 7 trillion from your 16.4 pounds pressure base to your 14.65 pounds pressure base.

A. Yes, that would be 7½ multiplied by 1.12. That gives about 8.34.

Q. Now, add up your 25½ trillion and your 8.4 8.34 trillion, and what does that give you?

A. 25½—I didn't quite get 25½.

Q. 25.3.

A. 25.3, I believe, and 8.34.

Q. Yes.

A. 8.34. We'll call it 8.3. You get about 33.6.

Q. 33.6 trillion?

A. Yes, that would be trillion.

Q. That would be the original reserve of the Panhandle field of Texas computed by that application of the pressure decline method, wouldn't it?

A. Well, that is your interpretation of it. It is not mine. That is the arithmetic. I am not trying to dodge the arithmetic at all. That is the arithmetic of your procedure that you have led me through.

Q. I used your withdrawal figure, you will admit, though, in doing it.

A. Yes, you used the withdrawal figures that I am using, converted over to 14.65.

Q. All right, I want you to do this for me: I want you to divide there and get the per acre content.

Mr. Keffer: Now, just a minute, Mr. Hughes. Did you understand that question?

The Witness: If he is trying to tack that per acre content onto me—I am going through again the arithmetic.

Mr. Keffer: All right, I want it clear that that is Mr. March's figure.

The Witness: Yes. I am going to divide 33.6 by the acreage of the field as I have used it on this zone map—1,468,329.

By Mr. March:

Q. Is that for the whole field?

A. Yes. So I will divide 33.6 by 1468, and the answer obtained by making that division is 22.9 million.

Q. 22.9 million Mcf.?

A. Yes. We were dealing with Mcf.—no, not Mcf.

Q. I mean cubic feet.

A. We are referring to 22.9 million cubic feet.

Q. All right.

A. This arithmetic that we are going through.

Q. All right, now, do you know any other way of applying the pressure decline method to the Panhandle field of Texas?

A. Yes, I know a number of ways.

Q. I'll let you go into those in a minute, but here you employ this same method and start out with your per acre content of 22.9 million and see what you would come out with.

A. I don't understand your question—your instruction. That was an instruction but I don't understand the instruction.

Q. All right, here is what you say you did:

"From this average *existant* pressure in each of the four zones and having my previously determined original gas content of each of the four zones I applied the pressure decline method to each zone and obtained an estimate of the amount of gas each zone had lost."

I want you to start out here and go through the same calculation except that you start off with the per acre content. What answer did you get?

A. You will have to show me how to do that. I don't know how you want me to do it.

Q. Could you work the pressure decline method when you had the per acre content to start with?

A. I have described what I did and I did it, but I don't understand what you mean for me to do with that 22.9.

And again, (pp. 11907-11921, Vol. 80),

Q. Mr. Hughes, you did not intend to state here that you had your per acre content before you start?

Mr. Keffer: I didn't say that.

By Mr. March:

Q. I mean in your formula. You didn't put the per acre content which you had arrived at by your 1. formula in your pressure decline formula when you started to work the pressure decline formula?

The Trial Examiner: Read that question, will you please, Mr. Reporter?

(The question referred to was read by the reporter as set forth above.)

By Mr. March:

Q. Did you utilize your per acre content that you had arrived at by your 1. formula in your pressure decline formula which you refer to here?

A. No, I don't know in what way it would enter into the formula.

Q. All right, now, I want you to tell me here for the record here—this is the best explanation you can make of the way you used the pressure decline method, is it, that you have here?

A. In testing I used it in the method that I have described.

Mr. Keffer: By the way, right there, Mr. March, as you have read a while ago—and I have never read this thing here—as you read, he didn't attempt to say how he applied the pressure decline formula.

Mr. March: If he didn't, I want to know how he did.

The Witness: This part here where you said you hadn't read before, you have to start in with the fact that I had the field divided into zones and I applied the pressure decline in each zone and I left the potential of each zone as an index or a ratio, if you would rather call it that, than to say that I had my previously determined content.

We can forget all about that being a previously determined content if you want to. We can just look at it as though it were a ratio of some content, whatever the content was.

Now, then, when I applied the pressure decline method to that I ended up with a figure that was so near the figure that I had previously estimated was the content of those zones that I split the difference. Now, the splitting of the difference left 1.075, and I had a 1 to start with. We can see what the pressure decline factor would have been.

Now, let's see what that would have been. The difference—I have 1.075 which is the split difference between 1 and something else. I must have had 1.150. Is that the arithmetic on that—1.150 plus 1 becomes 2.150 and divided by 2 is 1.075. Now, that is the degree of difference in the pressure decline method.

Now, at that point if I had not assumed a correct ratio—if you want to call it that for those zones—which I choose to call a previously determined content in this explanation, then that difference would have been much greater than that, and by spreading the difference they wouldn't have come out nearly as close as they did. That is the point I was trying to make that I considered it a reasonable check and the two methods I split the difference so that as I describe in this report that at that stage of my method it was tied in really to both the porosity thickness method and the pressure decline method.

Q. Is there any way it is humanly possible to check those calculations you made on the pressure thickness in arriving at that factor?

A. Well, I don't know that I have constantly been checking them lately.

Q. I mean to arrive at the factor today in this exhibit.

A. I don't have all of the intermediary steps between that point and the .92 but I have tried to tell you that later studies as time goes on—as time goes on those studies keep showing that the factor was a little too high. At present, as I have explained before, my opinion of the factor .92 that I am using is that it is a fair and reasonable one but that the information that I have as to the way the field is performing since I last made the study which re-

sulted in the .92, it indicates that that factor could be revised somewhat downward.

Q. I don't want to bear on this much longer. I would like to have you come over to this map and show me very briefly how you utilized the perssure decline method in estimating the reserves of the Texoma Natural Gas Company.

A. I have explained that in detail.

Q. Take it up zone by zone. You take your red zone and do what? Take it zone by zone. Take one zone and that is the way you do all of the zones—

Mr. Keffer: Mr. Examiner, the witness has described how he checked his factor against the pressure decline method. I don't know that he can say any more about that.

I will state this to the Examiner and to Mr. March, that Mr. Hughes *as* now in the course of preparation—it is not ready to be submitted and I am quite certain he is not ready yet to testify concerning it—a rather elaborate set of figures and computations upon the pressure decline method which will answer every question.

Mr. March: In that case there is no need to go any further with that line of inquiry.

Q. We are now to your .075 factor. You state here that in getting your .9 factor you have mentioned here 200,000 worthless acres of land. In what respect do you mention that 200,000 worthless acres of land?

A. After I explained how I tested my porosity thickness open flow method by means of the pressure decline method, then I changed the subject entirely as indicated by the fact that I have given the following paragraph a new number. It shows that I am starting now to explain some other things in connection with the history of the development of my estimate of reserves.

We left completely the discussion of the relation of how I tested the idea and the method with the pressure decline and we have gone now to an entirely different subject. That subject is shown in Paragraph No. 12 and there are several paragraphs following it on Page 5 of Exhibit No. 238.

Q. You just tell me in what respect you utilized the 200,000 acres.

A. I will explain it. This tells it in words I thought over during my leisure time.

Q. If that describes it, you need not read it.

A. "This method has been refined from time to time. The greatest refinement comes with the completions of new wells giving more complete information on the exact zoning of the field by potentials and by increasing the number of places in the field that known pressures may be obtained dufing each field-wide survey for pressures.

"Prior to 1937 I used my own idea as to the outline of the gas field but in 1937 I decided to accept the Texas Railroad Commission's outline of the field as exhibited on their pressure map."

You asked me that date the other day and I didn't remember it for sure but I have just read it.

"In doing this I had to include more than 200,000 acres of land which I had considered worthless for gas, and which I still consider worthless."

That goes on and has nothing to do with the testing of the pressure decline method against the porosity—

Q. What did it have to do with getting the .9 factor?

A. It didn't have a thing to do with the .9 factor.

Q. Let us see what you say in regard to the .9 factor. You state: "Additional refinements have come with subsequent balancing of estimated amounts of gas having gone out of the five zones, zone by zone, and totaled for the whole field, against the production figures from the whole field at a given date. This subsequent testing of the method has resulted in changes of the factor to the present one which is .919211."

I want to know where that data is where you balanced the production from these various zones and arrived at the .9 factor. I haven't seen it.

A. No, I don't have that, and as I have stated, that was the date in which these number of different tests had arrived at the time I used the .92.

Q. It is not in existence?

A. I don't know that it is in existence. I don't have it

here. I have several others that I have made since and I don't have them here.

Q. I want to see the ones you utilized in getting at this .9 factor because I can't test the .9 factor unless I have it here.

A. I told you I haven't it here and I have a number of tests of that factor.

Mr. March: I want the one you utilized in arriving at this factor and I will request counsel to make that available for me to examine.

Mr. Keffer: I do not know how we are going to get something that is not in existence. I will do my best but you won't want me to manufacture one for your special purposes, will you? You don't mean to imply that, do you, Mr. March.

Mr. March: You haven't manufactured one, have you?

Mr. Keffer: No, I haven't, but you are very insistent that one be furnished after the witness says that it isn't in existence. I don't know how I am going to do that unless I make one. You wouldn't want me to do that, would you, Mr. March?

Mr. March: If it is not in existence, I can't get it and I cannot test the factor.

The Witness: May I explain, a moment ago in reply to your remark that I could make a speech?

Mr. March: Wait until I get through questioning you—

The Witness: The explanation that Mr. Keffer gave to the Examiner a moment ago will take care of that speech business.

Mr. March: That is fine, very fine.

Q. In this Topeka case we referred to the other day, I requested you to find out for me what the estimate of reserves was that you had given for the field in that case. Did you find that out?

A. No, I didn't. I had no way of finding that out. I don't have a transcript of that. I can give you the date of the hearing and if you can locate a transcript of it I would be glad to have you read it.

Q. Give me the date of it.

A. I might as well give you all of these while I am on this subject.

Q. We will mark them—

A. They are not in presentable shape.

The Chicago case was in equity 13454, Federal Court, Chicago, Illinois, July 1934;

The Cities Service case was before the Kansas Corporation Commission in Topeka, Kansas at two different dates, January 1935 and April 1935;

The Chicago case before the Federal Power Commission was in May 1939—that is the one you are familiar with—and there are some other cases. These are cases in Texas. One was called the Shut Down case, Texoma Natural Gas Company versus Terrell, 59 Federal (2) 750, case heard 11-4-32. I furnished some affidavits in that case.

The next case—

Q. Just a minute. What was your estimate of reserves in that case?

A. I don't believe that an estimate of reserves was one of the items under consideration.

Q. What did you testify to in that case about?

A. The Shut Down case—it seems to me that it was largely matters of drainage and effective drainage.

Q. Was there a transcript taken—of course there was if it was in Federal Court. Was this in Federal Court?

A. Yes.

Q. Then a transcript was made.

A. The next one was a Market Demand case, Texoma Natural Gas Company versus Terrell, 2 Fed. Supp. 168, Feb. 3, 1933—hearing on interlocutory injunction. I furnished an affidavit in that case.

Q. For whom?

A. For the Texoma Natural Gas Company.

Q. What was the affidavit?

A. I don't know. These had to do with—

Q. You mean you furnished an affidavit and you don't know what was in that affidavit?

Mr. Keffer: He hasn't said that.

By Mr. March:

Q. What was in the affidavit?
A. I don't remember.

Mr. Keffer: I suggest that the affidavit is th best evidence of what was in it.

By Mr. March:

Q. Was it an estimate of reserves?

Mr. Keffer: Mr. March probably doesn't know, but the Examiner will appreciate that certain of these cases in Federal Court in application of temporary injunction or interlocutory injunction are submitted on affidavit form, not on question and answer form as given here. These affidavits are frequently lengthy and give many details. Certainly I wouldn't want this witness to testify as to what he gave in an affidavit nine years ago.

Mr. Lange: Did that interlocutory proceeding finally result in a hearing on the matter?

Mr. Keffer: I don't think any of those cases ever went beyond the stage of an application for a temporary injunction—wait just a minute. There was first the application for a temporary restraining order in each one of them. I expect that was granted upon the verified bill that was filed. I am supplying some things that I don't remember precisely but I am sure that was the normal case that was taken and these affidavits were submitted on the application for temporary injunction.

Sometimes applications for temporary injunctions and applications for permanent injunctions which could have been two separate transactions, were consolidated in one hearing and I am inclined now to believe they were in those cases, but there was never an appeal from the three judge trial in Federal Court to an appellate court.

Mr. Lange: What I was getting at was where they finally did hear any of the proceedings on the merits they did take the testimony.

Mr. Keffer: I did know that they did in some instances but I am not sure they did in all of the instances. I am

not quite certain. I think one went to the Supreme Court in the Consolidated case where there was testimony taken.

Mr. March: My question is whether or not there was an estimate of reserves given there. I will ask the witness.

Q. Was there an estimate of reserves given there, Mr. Hughes?

The Trial Examiner: If he remembers. Do you remember?

The Witness: I remember this, that if there was an estimate of reserves it wasn't contested in any way. I remember that definitely. In fact, I think in the next one I am coming to there was an estimate of reserves, although the case was against the Railroad Commission. As I remember it they didn't question our estimate of reserves in any way, shape or form. I could be wrong about that.

By Mr. March:

Q. The Railroad Commission didn't question your estimate of reserves?

A. As I remember it.

Q. Did they approve it?

A. I don't know—

Q. You mean you aren't sure?

A. I don't know that they put a stamp of approval on something. I am trying to tell you what happened in this case.

Q. Before we leave the other case, you don't remember whether you had an estimate of reserves in Federal Court?

A. I don't think there was an estimate of reserves of the entire field entered into it in these two last mentioned cases, the cases in Texas, the Shut Down case and the Market Demand case. I don't think that an estimate of reserves of the Texas Railroad Commission entered into those cases. I could be wrong but I am trying my best to remember whether an estimate of reserves came into those cases.

The next case was the Ratable Production case, House Bill No. 266. That was the Texoma Natural Gas Company versus Thompson. Thompson is one of the Railroad Commission's commissioners of Texas. It is in 14 Fed. Supp.

318, 300 U. S. 55, 81 L. E. 510. It says here, "Interlocutory injunction heard 9-19-35; tried 3-31-36."

Mr. Keffer: That was the one I was talking about.

Mr. Lange: And that is the one that preceded your hearing on the merits.

Mr. Keffer: Mr. Hughes has given there the correct style, however, that case was consolidated with a Consolidated Gas Utilities case and went up to the Supreme Court in the Consolidated Gas Utilities versus Thompson. There might be some confusion in the names but the citations will be correct.

By Mr. March:

Q. For whom did you testify in that case?.

A. The Texoma and the Consolidated.

Q. Did you have an estimate of reserves in that case?

A. I feel pretty sure that I had an estimate of reserves but I would have to check on that to be positive.

Q. Check that, will you please?

A. I don't know where I can check it until I get home and have a transcript of that made available.

Q. You mean, Mr. Hughes, you don't have a file on your estimate of reserves in the past?

A. I didn't say that I didn't have a file on my estimates of reserves. I can tell you this, that the estimate of reserves I have been using over the past several years back to and including the Cities Service case, couldn't be very far from around 18 or 18½ trillion, which is close to my present 19½ trillion. I can tell you that definitely so if you want to split hairs and know exactly the amount in each one of those cases it can be determined and if I am wrong the record will show it. I am not trying to misrepresent a thing in that statement.

Q. I am not saying that you are. You may proceed.

A. Those are the only ones I have.

Q. I do want to know if you can possibly get from your records what the percentage of drainage was for the Cities Service Company in the Topeka case.

A. I don't remember that I made a study of that. The only way I would know—I remember I made a study of the

reserves, but whether I made a study of the drainage at that time, the only way I could check that would be to obtain a copy of the transcript of that case. At the present time I don't know where I could get it and undoubtedly the Cities Service has it but I don't have it.

Mr. Hughes further testified (Vol. 85, pp. 12699-12721) as follows:

By Mr. March:

Q. I want to ask you if you did arrive at the pay thickness for the entire field?

A. No, definitely not. I think that has been clear in the record.

* * * * *

Q. Now, Mr. Hughes, your recollection was very very vague about the Chicago District pipe line case and I have gone to a lot of trouble to get the transcript of your testimony about it, and I want to ask you a couple of questions about it, and refresh your memory.

A. Which case is that, you say?

Q. That is this case: Chicago District Pipe Line, a corporation, plaintiff, versus Benjamin F. Lienheimer, Andrew Olsen, Charles E. Byer, J. D. Marnane, the persons constituting the Illinois Commerce Commission, and Otto Kerner, Attorney General of the State of Illinois, defendants; U. S. District Court, Northern District of Illinois, Eastern Division, No. 13,454 in equity, Chicago, Illinois, Tuesday, July 17, 1934, 2:30 p. m.—I beg your pardon. Your testimony begins on Wednesday, July 18, 1934, at 10:00 o'clock, a. m.

Now, you were asked this question:

"Q. Have you made a calculation, Mr. Hughes, for the purpose of determining the total amount of natural gas which was in the Texas Panhandle field prior to the beginning of withdrawals from that field?

"A. Yes, I have.

"Q. And what is your judgment in that regard based upon? Is it based upon the total area of the field as we know it?

"A. The information that has been obtained by drilling the various wells in the field.

"Q. What is your estimate?

"A. About 16¾ trillion cubic feet of gas.

"Q. Is that all the gas or the recoverable gas?
"A. That is what I consider recoverable gas."

That is found on Page 1090—Page 1092, rather. Then you state:

"Q. And the recoverable gas which you have given us a figure on is the gas that lies between two rock pressures of 25 and 430 pounds?"

Mr. Keffer: Now, just a moment. Mr. Hughes has never given any testimony in this case as to abandonment pressure. The matters which Mr. March is leading up to are quite definitely that.

Mr. March: No, I am not leading up to that.

Mr. Keffer: Yes, you are.

Mr. March: No, I'm not.

Mr. Keffer: Now, just a moment. Mr. March if he desires, may, of course, give the estimate made by Mr. Hughes as to recoverable gas, but I don't think he has the right on cross examination, at least, to prove by Mr. Hughes what Mr. Hughes might consider to be a proper abandonment pressure.

Mr. March: Mr. Hughes doesn't say anything about abandonment pressure, not a word, and I am not going to say a word about it.

Mr. Keffer: I think it does. I think what you just read could at least be interpreted as that. May it be understood, then, that the data you are reading shall not be considered in connection with any abandonment pressure?

Mr. March: If he doesn't say it. I don't want it to say it. I have no intention of bringing out abandonment pressure.

Mr. Keffer: It is your understanding that what you are reading has nothing to do with abandonment pressure and may not be so considered.

Mr. March: That's satisfactory with me, sure.

Mr. Keffer: All right.

Mr. March: I can't limit what the Examiner will do.

Mr. Keffer: You can make agreements here which are binding upon the Examiner. That's the only thing I want, and if you and I make a stipulation it is binding upon the Examiner, the Power Commission and the courts.

Mr. March: He doesn't mention abandonment pressure here and I am not going to, and as far as I am concerned, it has nothing to do with abandonment pressure.

Mr. Keffer: If it has nothing to do with it, then certainly you can make the stipulation, can't you?

Mr. March: The stipulation is it will not be considered in abandonment pressures?

Mr. Keffer: That's right.

Mr. March: I won't make any kind of stipulation in the record. The testimony will speak for itself. I am not bringing it out in regard to abandonment pressure.

Mr. Keffer: The only point is this, Mr. Examiner, if it is offered from the standpoint of abandonment pressures, an objection to it is good. If it is not offered for that purpose, perhaps the objection is not good.

Now, counsel can clear that up readily. Then if they refuse to do it, then I am going to object to the testimony on the basis that it does have some relevancy to abandonment pressure.

The Trial Examiner: The point is this, I think, that the matter you are referring to there has to do with Mr. Hughes' recovery factor.

Mr. March: It does. That's the point. It has to do with this recovery factor but not abandonment pressure.

Mr. Keffer: And it is limited to that.

Mr. March: That's right. I am not limiting a thing. It doesn't have anything to do with abandonment pressure but it does have to do with the recovery factor.

Mr. Keffer: You said that long ago.

Mr. March: But I am not stipulating with you on anything in the record.

Mr. Keffer: What do you mean? Then you mean you aren't limiting your offer to the recovery factor?

Mr. March: That's all I am bringing out here is in regard to the recovery factor.

Mr. Keffer: And it is offered for that limited purpose?

Mr. March: As far as I am concerned, it is not offered for any other purpose.

Mr. Keffer: As far as you are concerned, you are the only person concerned, because you are offering it.

The Trial Examiner: I think to be proper, Mr. Keffer, I think it is perfectly proper for Mr. March to read there from Mr. Hughes' former testimony if it pertains to Mr. Hughes' recovery factor.

Mr. Keffer: That's right, and it is limited to that.

The Trial Examiner: I don't think it would be proper to go so far as abandonment pressures. Mr. Hughes has not testified in a proceeding which has to do with abandonment pressures.

Mr. March: He doesn't say which one is right on these pressures. He has 100, pounds, 50 pounds, and 25 pounds in a series and I am not trying to confine him down to any abandonment pressures at all.

The Trial Examiner: Well, let's go ahead in the interest of saving time.

Mr. March: Well, then, I will read here to make it complete on Page 1094.

Mr. Keffer: You don't mind me looking here, do you? I have got to see what's coming. I haven't seen this.

Mr. March: No.

Q. You state on Page 1094:

"Q. Will you state how much gas has been withdrawn from the Texas Panhandle field for all purposes from the time of its discovery up to June 1st of this year, 1934?

"A. In round numbers that figure is 4.2 trillion cubic feet.

"The Master: Just about a quarter.

"A. Just about, yes, sir.

"By Mr. Davis:

"Q. That would leave—
"A. That would leave—
"Q. What recoverable gas reserve?
"A. About 12,550,000,000,000 cubic feet in the reservoir."

Q. Now, I ask you if that refreshes your memory in regard to your testimony as to your estimate of reserves in that case.

A. Well, I am assuming that all those figures that you have read were correctly transcribed and you mention there, I believe, 16 and what was that, three-quarters trillion?

Q. Your estimate of reserves that you have here on Page 1090, you state is about 16¾ trillion cubic feet of gas.

A. 16¾ trillion at 25 pounds?

Q. I will read what you stated over here:

"Q. At what rock pressure is it considered that gas is no longer commercially recoverable?

"A. In my figures I use 25 pounds as a point at which it would become uneconomical.

"Q. The recoverable gas which you have given us a figure on is the gas that lies between the two rock pressures of 25 and 430 pounds?

"A. Yes."

A. Yes, that's the point. I wanted to bring it down to the complete basis of the figures that I was mentioning from memory the other day which would be around 18 trillion. I was trying to refresh my memory as to about what that 16¾ trillion at 25 pounds abandonment pressure was on the comparable basis that I generally talk of and the total original reserves in place down to zero bottom hole, and that figure, as nearly as I can compute it rapidly here with the slide rule, would be slightly over 18 trillion.

Q. At zero pounds?

A. Yes, at zero pounds bottom hole. Now, what else was it you wanted to know about that?

Q. I want to know now why you considered that you had taken care of the recovery factor when you went down to 25 pounds and did not apply a 90 per cent recovery factor.

A. Well, of course, 25 pounds abandonment pressure has nothing to do with our consideration of the recovery factor. That is quite definite in the first place, and in the second place, as I remember it, that was the first, or very nearly the first time in which I had attempted to make an estimate

of reserves of the entire field in the Panhandle, and I have certainly learned a lot since then.

At that time I didn't know that a lot of these wells were going to go dead from water conditions and be abandoned, many of them at above 100 pounds and some of them as high as 200 pounds. There are many many things that I did not know about the field at that time that I do know about the field at this itme. In fact, I hadn't even noticed the fact that in computing down to 25 pounds abandonment the very arithmetic of that computation in the light of what I know now was incorrect, and that has been brought out in this record. It was an obvious error at that time and I admit it.

Q. Now, you use the words "recoverable gas reserves" as 12,550,000,000,000, so you apparently assume that all the gas could be recovered?

A. The explanation I just made was on that very question that you have just now asked.

Q. All right, sir. Then you state on Page 1148—no, on Page 1147:

"Q. Have you an opinion, Mr. Hughes, on the basis of the facts which are now known to you on the Texas Panhandle field as to the probable remaining life of that field as a natural gas field at this time?

"A. Based on the estimates I mentioned previously and in particular the more conservative estimate on 1936 withdrawals, it points to a life of about 11½ years from the present time."

Do you recall that statement?

A. I recall something of that, and I remember as I recall it, at that time the production from the field for stripping purposes was increasing by leaps and bounds.

Now, you read a statement that refers to the more conservative estimate for 1936. Without going back I would want to check that, but I think that at that time I projected the trend in the rate of increase in production from the field that was taking place at that moment and it continued to take place for quite a while after that hearing that you are reading from, so that quite definitely that statement was made in view of the existing conditions at that time and I am making that statement from memory and I am quite confident that that can be confirmed.

Q. Do you think the gas will be exhausted in eleven and a half years from 1934?

A. Well, all I need to do in connection with that is that at the time we were considering this very very great increase in the rate of production from that field, as I said before, that increase did continue for quite a few months, but then the law was passed in which this stripping of the sweet gas was made, was stopped, and the trend of production changed quite abruptly as is shown and definitely shown in the graph of annual production in Mr. Peterson's exhibit, so that graph explains exactly what my explanation is as to that. Of course the arithmetic at that date on given reserves and with an increased rate of production that was taking place at that time applied to the reserve, the arithmetic ended up with so many years. When that rate changed quite abruptly the arithmetic would be something else.

Q. Well, now, Mr. Hughes, I will refresh your memory on what you said would be the withdrawals for 1935. On Page 1134 of the transcript:

"Q. Have you made an estimate of the probable withdrawals of gas from the field for all purposes in 1935?

"A. I have.

"Q. What is your judgment?

"A. I have made two estimates on that. One is based year's activities which leads me to a figure which I do not think is out of line which would be an average daily withdrawal of 3,400,000,000, but the figure which I think is more conservative, although it is not necessarily more accurate, would be to take what happened during the past two years and let that be the guide, and that arrives at a figure of 3,060,000,000 cubic feet daily which would be a yearly withdrawal of 1,120,000,000,000."

Now, what were the withdrawals in 1935?

A. I don't know, but they are in evidence here and I think what you have just read explains what I had tried to recall from memory as to what that arithmetic involved. I am assuming that you are reading it, and I am assuming it was transcribed correctly.

Q. Now, I find here that—and which has been of great interest to me—that you gave an estimate of reserves according to your own statement here and I will read it to you, in 1932. On direct examination on Page 1087 you say this:

"Q. Are you the same Mr. C. Don Hughes who testified in 1932 before the Illinois Commission in a case involving the Peoples Gas, Light and Coke Company?

"A. I am."

And on over further here there is a statement that you didn't make an estimate of reserves. Is that correct?

A. A statement that I did or did not?

Q. That you did.

A. If it is in there it must be correct.

Q. Did you make an estimate of reserves in 1932?

A. I don't know. That could be determined. From my memory I didn't remember that I did. I may have. If I did, I did. I haven't tried to miscolor whether I did or not.

Q. All right, now, I have gone through this testimony and I have tried to find out what method you employed, and I can't do it, and I want you to see if you can throw any light upon it.

On Page—that is, in 1934—on Page 1176:

"Q. How did you determine what was originally in the field?

"A. Well, it is a long process. The rock pressures and thickness and pay saturations and porosity figures—I don't have any details of that with me. It varies from one part of the field to another and I try to go into the details of that sort of thing, and to try to go into the details of that sort of a thing, we would have to treat practically every area in the field separately."

Now, what method does that say? What is that method?

A. I think it says—I am not going to try to answer questions on that early stuff. I would have to refer to any reports that I may have had at that time. I have tried to give you a sort of a chronological picture of how my method was arrived at in the first place and how I have gone along from year to year, and some of those details at the different stages in which I was working, I don't know that I could even tell very specifically what they were at (illegible) different stages. I think that pretty well explains what was done. To go back of that to try to find the details, I wouldn't attempt to do here. I don't think it means anything, anyway.

Q. All right, sir. This is the only transcript I have been able to get ahold of. Now, of course, a trillion or so doesn't make much difference when you are estimating reserves, does it—a mistake of a trillion or so?

A. A mistake?

Q. Yes, a trillion or so when you are estimating reserves. Like you have an edition of your estimate coming out in 1932 and 1934 and 1939 and 1941 and 1945 and they are all different.

A. Assuming they would be different in 1941 and 1945.

Q. Well, in view of the fact they have been different in the past, I assume you will continue that in estimating reserves.

A. I told you when the conditions in the field at the date of the estimate shows that it is reasonable and practical to do so, I am constantly differing. I have made no attempt to show that the contrary was true.

Q. Now, this is one time I want to get in and—right now—and I don't think it advisable to wait until this other exhibit comes up.

Don't go into detail, but state just how you applied the pressure decline method to get that .9 factor. Now, there was something said about another exhibit which you had which brought that out very clearly. I want you to state in regard to this exhibit briefly how that was arrived at.

Mr. Spencer: Mr. Examiner, unless I am badly mistaken, I think Mr. Hughes had explained that at least a dozen times how he arrived at his factor.

Mr. March: No, he didn't explain how he arrived at—the last time, in how he arrived at it and how he checked against his pressure decline method. I started to have him do it and Mr. Keffer said he had another exhibit on that and he would wait to have him do it. I want him to do it right now. I don't want to take any chances on that other exhibit.

The Trial Examiner: Let us do this, Mr. March: As I recall it, that particular matter came up and you made a reservation at that time and it seems to me if an exhibit—future exhibit, is to come in that deals with that particular matter, it would be repetitious to go into it here now and then again on the other exhibit.

Q. Is there another exhibit, Mr. Hughes?

Mr. Spencer: Let me answer that, Mr. March.

Mr. March: All right.

Mr. Spencer: I will make this stipulation with you, Mr. March: Mr. Hughes will have an exhibit of that character which we will submit here, or he will be permitted to be cross examined on the subject.

Mr. March: All right. I just didn't want to let that slip away.

Now, I want to ask you just a couple more questions.

Q. As I understand, you used Mr. Peterson's estimate of withdrawals?

A. Yes, that's right. I used his table of withdrawals.

Q. All right, sir. Now, in averaging your pressures for various zones, did you average in the dry holes?

A. How's that?

Q. I said, in averaging your average pressures for each of your pressure bands, did you average in dry holes? In other words, when you got to a dry hole in a pressure band, did you say "Zero"?

A. You mean my zone map? My potentials?

Q. Yes, did you average in your dry holes, the open flow at the dry holes in getting your average open flows?

A. Well, I'll tell you, I took into account the dry holes. Those dry holes are what caused me to originally not include as much of an area in my outline of the field as the Railroad Commission includes.

Q. I understand.

A. So they were automatically in that in my idea of what those marginal areas would do. Now, any dry holes that have been drilled within the different zones since the time that I concluded that I had a reasonable figure representing the average of those zones has not gone into it for the same reason that I explained the other day why some of those inflated potentials in the other direction did not go into my average for a given zone.

Q. So in averaging your pressures in the—

A. Potentials, are you talking about?

Q. Potentials, yes—open flows.

In averaging your open flows in your various zones you did not average in your dry holes?

A. I have explained that.

Q. Did you? I'll make this very simple. You see up here on this map Moore County?

A. Yes.

Q. You see that red band there?

A. Yes.

Q. That red pressure band?

A. Yes.

Q. I want to know in getting your average open flows for the red band whether or not you averaged in all of the dry holes as zero?

A. Well, if those dry holes existed and were in that band at the time I was arriving at my average, very likely they were in. However, dry holes that have come in since I decided that I had a good average to use, wouldn't go into them.

Q. I see. So in every one of these bands—

A. Of course, in a red area there aren't very many dry holes. Dry holes in the red area are very very much the exception. Of course there are some. I see here some dry holes in that area in the red up there that you were asking me about right near those Ingerton wells here we were talking about the other day. I don't think I pointed them out at that time but this map shows that in what I called the red area within a mile and a half of that Ingerton well, there are about four dry holes.

Q. You averaged all of those in?

A. That would show that my treatment of that area and the color that I show is certainly very very reasonable, even though the one well might be pointed out as being a little higher than the average color band indicates.

Q. Now, if you average in the dry holes in the red area, did you average them in in all of the open flow bands as you came to them?

A. Well, I have tried to explain to you what I must have done. If those dry holes had existed, that is, had been drilled at the time that I was getting the information on my averages I would probably have used them. However, I want to show further that within any of the zones, getting up into the high value acreage, there are not very many dry holes.

Theoretically there shouldn't be any, but in actual practice they do drill them once in a while.

Mr. Hughes further testified on cross examination (Vol. 90, pp. 13842-13846) as follows:

Q. Did you prepare this exhibit since you have been in Denver, Colorado?

A. The part that has to do with Mr. Hammer obviously was because I never heard of his information until I came up here. The other part, as I said, has been growing for a number of years. The first year that the Railroad Commission of Texas gave us a weighted average pressure I tried the pressure decline method. It gave me a figure that was obviously too high and ever since then—every time they bring a figure out I again apply it and I find that the things are changing and you can't get consistent results and the first part of my exhibit is a definite explanation of what that study results in.

Q. You make one of the strangest statements I ever heard of over here on the first page of your statement—on page 20. You make this statement:

"An extension of this trend points to an Original Reserve of 16.3 trillion for the field. If this is correct, then my estimate of approximately 19¼ trillion is too high. Even though this is the indication, I am inclined to stand on the evidence that 19¼ is a reasonable figure and that the manner in which I arrived at it is reasonable."

Now I want to ask you this question: How could a figure of 19¼ trillion be reasonable when you say that everything points to a reserve of four trillion less than that?

A. Well, I didn't say that everything points to it. I am at that point discussing the extension of a trend which has been going on for five years, very consistently in the Texas Panhandle and that has a bearing on what I was talking about a moment ago. I am definitely interested in knowing what is going on in that reservoir. I want to know how it is performing from year to year and in order to do that I construct these curves which are critical as to the method of showing what is going on, and I have found that from year to year at each new period that we have a survey that we are finding that the field is actually performing by producing less amount per pound drop than it had been before.

Now, I can't shut my eyes to that trend. Now, I don't know that it is going to continue, but I am saying in this

statement that if that trend continues in a straight line, and you will see by referring to Chart C that it is a fairly straight line—now if that trend continues down to the end of the life of the field, it means that the field has 16.3 trillion in it.

Now, I am not convinced that that trend is going to continue. I have already arrived in other manners at an estimate of 19¼ trillion which is a figure that is higher than the one I have just quoted.

Q. 16.3 trillion—if it could—16.3 trillion and 19¼ trillion couldn't be right at the same time. One of them has got to be wrong. Now which horse are you going to ride?

A. I am watching the trend of events. The longer this situation continues to exist that has been existing for the past five years, the more convinced and the more confidence I have in the trend as shown on Chart C.

Q. Are you trying to say that the reserves are somewhere between 16.3 trillion and 19¼ trillion?

A. No, not at this point, but if that trend continues that is apt to be my conclusion a little later on down the line. For the present I am willing to stand on the 19¼.

Q. You may change your estimate at any time within four trillion?

A. When the information that is the most pertinent in the field shows that I need to revise my figure I will revise it.

Q. Just as you have done in the past.

A. Yes, sir.

Q. You have revised it upwards from 16.3 trillion since 1934.

A. 16.3—I believe you will recall that that was on a 25 pound abandonment and I converted it the day you brought that figure in, and that figure is about 18 trillion; so let's forget that 16.3. I have revised it from 18 trillion to 19¼ trillion.

Q. You did testify that the reserves will only last eleven years from 1934.

A. I think that was very definitely explained in the light of what was going on at a certain time. The arithmetic showed a certain figure.

Q. Every time you make your calculations the arithmetic shows a different figure, doesn't it?

A. As to what?

Q. You had a calculation last year where your arithmetic shows one figure for reserves and you make one this year that shows another figure for the reserves.

A. We were talking about the arithmetic on the life of the field. Now what kind of arithmetic are you talking about?

Q. Every time you have made an estimate of the life of the reserves of the Texas Panhandle Field it has been different, hasn't it?

A. Not every time. I have just about decided that in the light of some of these things that are taking place in the reservoir that have to do with these decline studies that there is not much use to keep changing these figures just a small amount until enough evidence piles up that it should be changed materially, and I have brought out—I have stated quite carefully in this particular case that the figure that I am using today is the same figure I used in Chicago in 1939 but that the tendency of the performance—the conditions that prevail in the field today would allow me to revise that slightly downward, but again I am waiting for more evidence to build up showing that an appreciable change should be made. It might tend to conform to the one I am using.

Q. How long do you think it will be before anybody can tell what the reserves of the Panhandle Field are, approximately?

A. Well, nobody will ever know what the reserves were until the last cubic foot, or approximately, has been produced.

Mr. Hughes further testified on cross examination (Vol. 91, pp. 13880-13885) as follows:

Q. Now, you made a great many statements here about the equalized pressure or the equilibrium pressure, which I believe is what you called it. You stated here on Page 17: "I believe the declines as a whole have been in richer than average areas and if the entire field were shut in today until the pressures became equalized, the final pressure would be less in pounds than our present so-called weighted average pressure."

Were you referring there to the weighted average pressure of the Railroad Commission of Texas?

A. Yes.

Q. You were not referring to Mr. Hammer's weighted average pressure?

A. It wouldn't make any difference. I don't see much difference between his and theirs as to the different dates. One date in particular is a little different. The weighted average pressure arrived at by weighting is the weighted average I am talking about, and at the time this was written I hadn't seen his figures so I was obviously referring to the Railroad Commission's pressure.

Q. This exhibit was prepared in rebuttal to Mr. Hammer's exhibit, wasn't it?

A. I told you yesterday the last part of the exhibit was; the first part was a study I made long before I heard of Mr. Hammer's exhibit.

Q. When was the first part prepared?

A. Well, I don't even know for sure.

Q. When did you have the first part typed up?

A. When was it typed up?

Q. Yes.

A. I don't know. I might be able to check back and give you the exact date.

Q. Has it been since you have been here in Denver?

A. This particular typing of it, yes.

Q. Here is what disturbs me: "The final pressure would be less in pounds than our present so-called weighted average pressure." Now, do you know what the equilibrium pressure would be if the field were shut in and allowed to equalize?

A. No, I don't, I'm sorry to state, and I don't think anybody knows for sure what it would be, but I am quite positive it would be something less than the figure that we arrived at by weighting the field by acreage only.

What page are you reading from?

Q. Page 17. If you don't know what the equilibrium pressure will be, how can you come up here and say it will be less than the weighted average pressure?

A. I am not quite sure it will be less.

Q. How do you know?

A. In my opinion I don't think there is any doubt but what this is true that the great bulk of the withdrawals and the pressure losses throughout the field have taken place in richer than average areas. The greatest portion of the

field today that remains at high pressures is very lean, so if you would shut the field in today, shut all of the wells in today and allow equilibrium to take place, those high pressure and lean areas would attempt by migration to build that pressure up. As that lean amount of gas migrated over into the low pressure areas which have larger content, they wouldn't fill it up quite as much in proportion as to what they are losing; so you finally would arrive at an equilibrium pressure that wouldn't be as great as this weighted average pressure we arrive at when we weight it on the acreage alone.

Q. How much less would it be?

A. I don't know.

Q. You don't have any idea?

A. I don't know how much less it would be.

Q. You haven't given it any consideration as to whether it would be a hundred pounds less or ten pounds less?

A. I haven't made any estimate of what it might be for the reasons that I have explained which are good sound geological reasons. I am quite sure it would be less than the weighted average pressure arrived at today on acreage.

Q. Why haven't you made some effort to ascertain how much less it would be?

A. I don't think—

Q. It couldn't be too much less, could it?

A. What do you mean, too much less?

Q. I mean by that, it couldn't be very many pounds less of the weighted average pressure of the field.

A. That wouldn't have anything to do with it. The facts that I have explained could allow quite a great variation between the finally arrived at equilibrium pressure and today's weighted average pressure. It could be quite a sizeable amount, in my opinion.

Q. It is one of the relevant things of yours that can't be measured or appraised?

A. I haven't attempted to measure it. The conditions I have described are present in the field and the decisions following the observations of those conditions would lead quite definitely to the conclusion that that equilibrium pressure would be less than the weighted average pressure.

Q. Now, Mr. Hughes, since you have such a thorough knowledge of everything that has happened in the field, will you tell us this: How long would it take us, approximately,

if the field were shut in tomorrow when the equilibrium pressure would be reached?

A. I haven't any idea.

Q. I thought you studied the movement of gas and the obstacles of the movement of gas together. Do you have any idea as to how long it would take to reach 100 per cent equilibrium?

A. It would take a long time.

Q. A hundred years?

A. It would take a very long time.

Q. A very long time?

A. Yes.

Q. What does a long time mean to you?

A. We would be dead and gone before it reached that equilibrium pressure.

* * * * *

And again (pp. 13911-13915, Vol. 91.)

Q. Do you know of any field as large as the Panhandle field of Texas where the pressure decline method has been applied where the pressure pound and production didn't vary from year to year but didn't average out on a straight line?

A. Well, the first thought on that question is that I don't know of any other field in the world that is as large as the Panhandle field with respect to its reserves. I do know of a field that has more acres in it, but now to come to the second part of your question—

Q. What field has more acres?

A. The Hugoton field.

Q. Right north of this Panhandle field?

A. Yes, that is north.

Now, with respect to the second part of your question, the only way you can answer that is by making studies of the fields. Whether they do or not can only be determined by studying the field and when you study the field if they do give consistent results you conclude that you can apply Boyle's Law—I mean the pressure decline method—and in studying the field if you find that it does not give consistent results from time to time you either conclude that the whole thing is worthless and throw it out the window, or if it goes along consistently and shows from one period to the next

over a consistent number of periods that there is a trend being established, then I think you are at liberty to take into account the trend that is being exhibited and interpret your answers in the light of the trend.

Q. I notice in this rebuttal exhibit that you stay away from the part of Mr. Hammer's exhibit where he makes his estimate of the recoverable reserves of the Canadian River Gas Company. In other words, you don't have any rebuttal to that. You just take his figures on the whole field.

Now, I will ask you this question: I will ask you the question as to whether or not you have plotted production against pressure decline utilizing his figures just on the Canadian River part of his estimate.

A. Let me see. Will you restate that?

Q. I want to know whether or not you have utilized his figures and have plotted the production versus the pressure decline on the Canadian River part of his estimate.

A. You mean by that on the Canadian River acreage or on the quadrants in the Canadian River—

Q. First on the Canadian River acreage.

A. Well, I couldn't find in his working sheets the figures that would have permitted me to do that, so the answer to that portion of it is no.

Now whether I have plotted the comparable study on his quadrants which contain some Canadian River acreage, I don't know. I would have to refer to my work sheets on what I have done with his figures before I could answer that question.

Q. Have you ever plotted the production of the Canadian River wells against the pressure drops of the Canadian River wells through the year 1940 to ascertain whether or not they do not approach a straight line?

A. Well, I am quite sure that I haven't done that.

Q. You haven't done it, so you wouldn't—

A. Through 1940.

Q. Yes. You wouldn't know whether or not that reveals a straight line or not. You wouldn't know whether it would approach a straight line?

A. A straight line with respect to what?

Q. Similar to this Chart C-1. In other words, taking the

example to the left there and plotting your production against your pressure decline through 1940 on Canadian River wells.

A. Oh, you mean just on the wells alone?

Q. Yes, production from the wells and pressure decline from Canadian River's own wells.

A. And on each well, just production on each well?

Q. Total production decline versus pressure decline.

A. Well, how would you arrive at the pressure decline? I want to know for sure what it is you are asking me.

Q. I am asking you if you ever plotted the Canadian River well production against the Canadian River pressure decline similar to the way that you have plotted the production and pressure declines for the whole field on this Chart C-1 in the left-hand diagram.

A. Well, if you mean plotting the grand total of Canadian River production against the arithmetical average pressures of the wells, that is of a given date and new wells that come in and just bring them into the picture and all that, you mean?

Q. I mean this: You know how you did this in Column No. 1 there?

A. Yes.

Q. I mean doing it just like you did that.

A. No, I haven't.

Hughes further testified on cross examination (Vol. 94, pp. 14490-14499) as follows:

Q. Now, Mr. Hughes, your next move here, as you say, is to assign an open flow to each one of your sections. That's right, isn't it?

A. That's right.

Q. By an open flow do you mean what the open flow would be at virgin pressure conditions?

A. That's my interpretation and in fact my intention, and since these open flows that went into the study that I have made on Canadian River Gas Company were most carefully carried back by them to virgin pressure conditions, they are more nearly actual virgin pressure conditions than I have heretofore used and as I have explained before—

Q. All right, in assigning the open flow to each section, did you, where there were wells in the section, take the

arithmetical average of the various open flows of the various wells in the section?

A. I don't think I did. In fact, I can't think of very many sections that actually have more than one well in them. There are a few cases in some of those sections I believe that the tracts were treated separately so that it would not necessarily be an arithmetical average. Whether or not I did that would have depended upon the location of those wells in the section, the geological conditions in the area. There are a number of things that went into my consideration of a given tract before the actual open flow figure was determined.

Q. Now, so there we likewise differ from the way you worked your field as a whole. You didn't take the field as a whole, you took the average open flows within your various pressure bands, pretty well, didn't you?

A. From the pressure bands. I averaged the open flow for the zone.

Q. Zone, that's what I mean.

A. Yes.

Q. Now, in the case of the section, though, you don't do that. You approximate what the open flow should be based upon these various wells, where there are wells in the section.

A. Well, I said that I don't remember taking the arithmetical average. Now, in the first place let's come back and see about how many cases there would be. I don't suppose there would be over—oh, a dozen sections in the whole area that have more than one well in the given section. I am just looking very roughly and hurriedly. I don't want to be pinned down to that dozen, either, but in so far as to the acreage that I am dealing with—this what I am talking about is incidental and if there were more than one well in a given section, the information on both wells we would use.

Now, if you want to get specific on some section, why, I might be able to tell you whether it is an arithmetical average of the potentials. I don't remember. I can't remember whether it was of not. I could tell you this: It wouldn't need to be—for instance, if you have a section of land with two wells down on one side of it that were pretty good sized wells and immediately on the north line in the next section was a

very very small well, naturally I wouldn't appraise that section that had those two good wells down along the south line according to the potential arithmetical potential of those two wells. I would let the small well along the north line have a bearing on the classification that I would assign to that section.

Q. Without going into the thing in detail, you know quite well, do you not, you didn't take the arithmetical averages?

A. I don't believe that it would work out that I did, but I am telling you what was involved in whatever I took.

Q. Don't you know what you did in this case? We have to surmise what you did?

A. I think I have described the procedure that I would go through in appraising a section.

Q. When did you go through all this procedure in estimating the Canadian River acreage?

A. I don't remember exactly.

Q. It has been since you came to Denver, hasn't it?

A. No, my goodness!

Q. When?

A. I don't remember.

Q. Don't you know whether it was in 1940 or in 1939?

A. Well, I told you the date of the map. The exhibit, Exhibit No. 212, is dated the first of 1939; I told you a field-wide section by section survey would be a year later. That would be the first of 1940, wouldn't it?

Q. Yes.

A. I would assume the details on this Canadian River were probably worked out about a year ago on that basis. In trying to reconstruct here what took place, I am trying to give you just what did take place.

Q. In some cases you are not quite sure yourself just what did take place?

A. Well, I have described the procedure.

Mr. Spencer: He is not able to tell you the results section by section, Mr. March.

By Mr. March:

Q. Now, Mr. Hughes, when you came to a section where there was a well right in the middle of it, did you assign the open flow of that well to the section?

A. Again I cannot remember, but let me tell you the line of reasoning I would have used in a case like that. Had that well that was in the middle of a section been greatly different from the sizes of wells immediately around that section, if that were true I certainly would not have assigned the value of that one well. If I had it would have been due to conditions that I considered making it representative.

Under the set of conditions I have described, I have tried to picture a situation that would fit a case where according to my procedure I would not have given it a figure. Again I don't remember all of the different ones. You have 13 pages in my working sheets, as I remember it, and each one of those pages have about 40 entries on each page, so there must be approximately 400 entries.

Q. In other words, you have 400 individual estimates of reserves on your working papers, haven't you?

A. They are estimates on reserves based upon the figure which I have just given you on approximately 400 tracts of land.

Q. In other words, what you are doing is taking one little old tract of land, an arbitrary section, and estimating the reserves for it and then adding them all up to get the total?

A. Taking it arbitrarily?

Q. Well, naturally you didn't have anything to do—

The Trial Examiner: He told you, Mr. March, that he has taken them section by section. It is quite clear in the record.

Mr. March: Yes, I think it is quite clear, too, that he has made 400 individual estimates of reserves.

Q. You have estimated the reserves on each of the tracts, haven't you?

A. There is an estimate of reserves on each tract.

Q. That is right. Mr. Hughes, do you think you could tell anything about the reserves of a given tract of land by taking that one tract and making an estimate of reserves for it? Do you think you could get a correct reserve on the one tract of land?

A. If I didn't think I was getting a correct picture, I

certainly wouldn't have been spending these years doing that in the Panhandle field. My clients must have been thinking I have been doing it or they wouldn't have been paying me all these years to keep doing it.

Q. Then you wouldn't criticise Mr. Hammer in so far as attempting to estimate Canadian River reserves by just taking the quadrants the Canadian River reserves are in? In case you did disagree with his method of averaging in so far as attempting to estimate reserves for the Canadian River acreage alone, you wouldn't criticise him for attempting to do that, would you?

A. Apparently I have criticised him indirectly in that I didn't do it. I wanted to get down to smaller tracts in treating the Canadian River leases.

Mr. Spencer: I think you misunderstood his question, Mr. Hughes.

By Mr. March:

Q. The point I am stating here is, Mr. Hammer took in estimating the reserves the quadrant in which the Canadian River had acreage as some of the acreage owned there was owned by other companies. You would not criticise him for limiting his estimate of Canadian River reserves to that area in view of the fact you have taken smaller areas and estimated Canadian River reserves, would you?

Mr. Spencer: Mr. March, I don't want to interrupt your cross examination—I want to help you—but as I understand your question, it is "you wouldn't criticise Mr. Hammer for estimating reserves based upon his quadrants, when you have gone much further in using a much smaller unit in which to estimate it." Is that the point you have in mind?

Mr. March: In view of the fact he estimates reserves for smaller units or whether he would criticise Mr. Hammer for using the Canadian River quadrants for the Canadian River Gas Company and not take the whole field into consideration. That is what I have in mind.

Mr. Spencer: You are talking about gas in place?

Mr. March: No, I am not talking about gas in place but I am talking about recoverable gas. I want to have it understood that I am talking about recoverable gas.

Mr. Spencer: I would like to have it understood that I want the question to be clear as to what he is answering.

By Mr. March:

Q. Do you understand my question?

A. I think it is a pretty difficult question to answer.

Q. It is obviously in the record that you have taken smaller units than Mr. Hammer thought of. So much for that step.

Then you multiply your acreage in each section by the potential which you have allocated, do you not?

A. That is right.

Q. In that respect you do just as you did before in your other estimate in so far as that particular step is concerned?

A. Yes, that step is the same.

Q. Then you do the same. So much for that step.

Then you would go a step further. You then do what?

A. Well, for convenience, on the working papers that I have set out there are the additional steps that carry this on through, making an estimate of remaining reserves at different dates that are involved. At that point that step we have just finished where we have multiplied acres by potential, at that point we can multiply that product acre by potential by my factor .92 and that gives me the estimated original reserves of gas.

Q. Yes, but you don't do that as you have pressure which comes in there.

A. No. I want to point out to you that I do that. If you go down to the bottom; that is, the sum of all of those acres times potential products on the last page, you will see a grand total figure which is referred to in my written statement. That grand total figure is multiplied by my factor .92 which gives me directly my estimate of original reserves in the Canadian River acreage.

Q. Why do you have pressure involved over here after you multiply your acres by potential? You say that the pressure factor in the left-hand column on the first well is indicated as 425 pounds at .9873.

A. I just explained to you—apparently you weren't

listening—that these next steps you are going to point to have to do with estimation of reserves at later dates. I also want to point out that at the end of this step just made in taking these grand totals here on the last page times the potential you will find a figure which I have referred to in my written statement to which I applied my .919211 factor which gives me without going into pressures or anything, and without referring to these columns on these working sheets, I have a figure that gives me my estimate of original reserves of the Canadian River Gas Company leases.

Mr. Spencer: At zero wellhead.

The Witness: At zero wellhead—at zero bottom hole. At that stage I have my estimate of original reserves. What you are stating has to do with something else and—

Hughes also testified on cross examination (Vol. 94, pp. 14502-14508) as follows:

Q. When you brought pressures to bear here in the Canadian River estimates of the remaining reserves as of 1932, you brought into play the pressure decline method which you condemn, don't you?

A. I brought it into play in a manner which I thought and which I consider that some of it, not working in the field as a whole, had been ironed out in that I have attempted to classify acreage according to volume. That was the reason I classified my acreage in accordance with potentials.

Q. You are now saying that the pressure decline method will work in estimating the remaining reserves of the Canadian River acreage?

A. Well, that's the way I have applied it, yes.

Q. And that is your position?

A. It has been my position all along that the pressure decline method should work if we weight the field, and if we know the correct manner of applying it in accordance with volume. My open flow classification of the tract by tract study of Canadian River acreage is my opinion as to the closest approximation on a volume basis. Now, there are some things, however, going on in the Texas Panhandle field that as time goes on and as we study them, and if it continues, why, they may be well recognized that the pressure

decline method is not even working, assuming we did have that weighted volume.

Q. You mean it is—

A. So that that is getting into something else that—

Q. It may be that it will not even be working in the Canadian River acreage as you apply the method to the Canadian River acreage?

A. Well, if it isn't working in the manner that I have applied it, the other method that would be working if these studies lead to the fact that there is another situation that is causing it to work otherwise, it will certainly show that Canadian River has been suffering a whole lot more drainage than this study shows, quite definitely.

Q. How could the pressure decline method show anything if it wasn't working?

A. Well, I have explained I am assuming that it is working in this particular study.

Q. In this particular study?

A. But I am telling you what would be the result if it is not working in the manner that I am assuming it, but if it is working in the manner that fits in with this study that I am making currently, it is a method that I am not ready to sponsor. It is a well-known and well-recognized relationship but I am not willing to sponsor that application to the Panhandle field, but if it is working, if it turns out a few years from now that it has been working in that manner all along, I have terribly underestimated the amount of loss by drainage from Canadian River acreage and I know that very definitely.

Q. You say you are experimenting on that method now?

A. I am not experimenting on it. I am merely watching it. I am watching the performance of the field. At the present date it indicates that the field is working under that method but I am not willing to agree as yet that it is because I want a little more history to prove it, but the history for the past five years has definitely indicated that there is something going on down there that would fit in with this other method and it is the method that Mr. Gill referred to the other day and as I said before—

Q. By the way, you might just tell us how that method differs from all three of these other methods—of these other two methods.

A. Well, it is very simple in that we have been assuming all along that the Texas Panhandle reservoir was under 100 per cent volumetric control, and in a reservoir which is under volumetric control, Boyle's Law works in such a manner that the remaining reserves in the field are always directly proportional to the remaining pressures in the field.

Now, the thing that I am talking about is a reservoir that is under capillary control and a reservoir under capillary control as it so works out, the remaining reserve in the field varies directly as the squares of the remaining pressure at the time, and it is quite a different arrangement. It would involve an entirely different manner of computing this drainage in this study I have made. It is a well-recognized method. There is no question about that, but I can tell you very definitely that if that method which applies to reservoirs under capillary control is working in the Texas Panhandle field, I can repeat again I have very grossly underestimated the amount of drainage that the Canadian River acreage has been suffering.

Q. I notice here in working your pressure decline method the new thing here strikes me is that instead of using pressure and production, you have left production clear out of it and use your—what, in place of production?

A. Well, here is the only thing: You are trying to tie this in with production. Most of those leases have never had any well on them and there is no production that you can put up, alongside of the pressure drop in each one of those tracts. What I have done, I have estimated the content of each one of those tracts and at the various dates depending upon the pressures existing on those tracts, I have applied Boyle's Law to arrive at the remaining estimated reserves of those tracts. It is very simple what I have done. It is a simple application of Boyle's law, tract by tract.

Q. Nominally, application of Boyle's law would bring your production to bear, wouldn't it?

A. You are talking about the pressure decline method and I am talking about an application of Boyle's law based upon the estimate of reserves that I estimated was originally in each tract.

Q. How does Boyle's law differ from the pressure decline method?

A. Well, that was explained at length the other day.

Q. By Mr. Gill, but I want you to explain it.

A. I explained it.

Q. You did?

A. I did, at length.

Q. All right. Now, you get a product which is considerably lower, which is some lower than the product—your original reserve figure. For example, in this first one here I see you get a product—just a moment here—the first product I see is 632 there as of 1932. What is your original reserve there in that first illustration?

A. Well, these figures haven't been as to each tract by tract—have not been converted to reserves. The product that you are pointing to as the product of acres times MMcF. under the 1932 period is 632 compared with an original acre times MMcF. product under virgin pressure conditions of 640.

Q. Using in the latter case, of course, your pressures?

A. That's right. The pressure in that particular tract had gone down from 430 to 425 and that difference between 640 and 632 is an expression of the difference between 430 pounds virgin wellhead pressure corrected down to reservoir pressure, and 425 pounds remaining pressure at 1932 corrected down to reservoir pressure.

Q. Now, Mr. Hughes, is there any way that I could compare your original reserve for each section to your remaining reserves as of 1932, 1938 and 1939, for each section? Have you got a calculation showing that?

A. These are the basic figures that we are pointing to. All you would need to do with each one of these figures under the tract would be to take that product which is acre times MMcF. and multiply it by my conversion factor of .919211. That would convert each one of those acres times MMcF. products into my estimate of gas in place at zero bottom hole.

The additional method of estimating reserves which Hughes referred to in his cross examination, supra (pp. 14504-14505) was incorporated in Exhibit 315. This exhibit was offered in evidence, which offer was rejected by the Examiner and exception taken, as shown by the following pages of the Record, Vol. 102, pp. 15871-15876:

By Mr. Keffer:

Q. You are the same C. Don Hughes who has testified before in this case, are you not?

A. Yes, I am.

Q. And you have been sworn?

A. Yes.

Q. Mr. Hughes, you have prepared a written statement with respect to some further testimony on reserves in the field, have you not?

A. Yes.

Mr. March: Now, Mr. Examiner—

Trial Examiner: (interposing) Just a moment.

By Mr. Keffer:

Q. Is this the instrument?

A. Yes, it is.

Mr. Keffer: May this instrument be marked?

Trial Examiner: Mark the document referred to by the Witness Hughes for identification as Exhibit 315.

(Exhibit 315, Witness Hughes, marked for identification.)

Mr. March: Mr. Examiner, we strenuously object to any further testimony at this late date in regard to gas reserves. Obviously, this will reopen the whole question of gas reserves. I would like to direct the Examiner's attention to this, that during the last five months, Respondents had every opportunity to come in here and bring on geologists and present estimates of reserves and give other reserve testimony. Not only that, but they were given adequate opportunity before we recessed in Denver to do that and this hearing was convened for the specific purpose of taking the testimony of Christy Payne and Mr. Lerch.

As a matter of fact, the whole thing that prompted this additional hearing in Washington was the application to take the depositions of Christy Payne and F. H. Lerch, Jr. Now, I want to refer the Examiner to that application and it states very specifically there that matters would be limited to that testimony of F. H. Lerch and Christy Payne.

To bring this testimony in here will reopen the hearing

on reserves. It will bring into play new issues. It will otherwise continue this hearing indefinitely and I think any court of law in this country would rule that the respondents have certainly had, in five months, adequate opportunity to put on estimates of reserves. As a matter of fact, this witness alone was in Denver for almost two months.

Trial Examiner: Mr. March, let's make this as short as we possibly can. I don't need any extended argument, I don't believe.

Mr. March: Very well, I have all the argument I care to make.

Trial Examiner: Have you anything to say, Mr. Keffer?

Mr. Keffer: Mr. Examiner, very briefly this Exhibit 315 merely presents an issue which was raised in the hearing at Denver. The Examiner will recall that Mr. Hughes, while on the witness stand on cross examination, testified as to a method or an estimate based upon pressures squared which matter had been brought out by Mr. March in his cross examination.

This is simply gathering up the loose ends on that. As it stands in the record now, it perhaps is due us or, at least, possibly the burden is upon us to make an explanation of just what he meant on that and that is all this purports to do. It is merely redirect of a matter that was brought out on cross examination.

Trial Examiner: I might say, Mr. Keffer, that the Examiner at this stage of the proceeding is very hesitant to take further testimony with respect to reserves of the Panhandle field.

I feel that every opportunity was afforded both the Respondent and the Commission's counsel to present evidence pertaining to reserves in the field at the time we were in Denver and the purpose of this hearing today was, of course, directed to taking of the testimony of Mr. Payne and Mr. Lerch.

Now, I don't intend to foreclose consideration of any other matter at this time but I do feel that we have adequate testimony in the record pertaining to the reserves or, at

least, that ample opportunity has been afforded to submit that testimony in the proceeding we had at Denver.

Therefore, the Examiner is inclined to sustain Commission's counsel's objection to the introduction of any further testimony on reserves at this time.

Mr. Keffer: I take it, Mr. Examiner, in order that we might complete our record in this respect, and to save time and eliminate the reading of what the testimony would be, let the reporter copy it in.

Mr. March: We object to this going in the record. Mr. Examiner, that is just putting it in the backdoor, copying it into the record. This is a new estimate of reserves. I have just glanced through it, but we don't object to having the thing marked for identification so you will have a record shown but that is just a way of putting the thing into the record, having it copied into the record.

Mr. Keffer: Mr. Examiner, I don't know any way of making a record, in fact, there isn't any way except to state what the testimony will be and I cannot do it except to read it. I thought we might save the time of the Examiner and counsel by putting it in this way.

Trial Examiner: Why not do this, Mr. Keffer. It is your desire to make an offer of proof, I take it?

Mr. Keffer: That is it exactly but I must show what the offer will be.

Trial Examiner: I was going to suggest that inasmuch as this is part of a document which has been marked for identification as Exhibit 315, perhaps it would be expedient to make an offer of the exhibit itself and the Examiner, in conformity with the statement he has made, will reject the offer and then the exhibit is a part of the record.

Mr. Spencer: If it may be understood, Mr. Examiner, that in making such an offer, the written statement will be considered, for the purpose of the offer, as being a part of the record.

Trial Examiner: I think it will be so understood.

Mr. March: That is satisfactory but did I understand the

Examiner to say it will be a part of the record, even though it is rejected?

Trial Examiner: If I said that, that is an erroneous statement. I meant even though this exhibit were rejected, it still went to the Commission as a part of the proceedings. That is what I intended to say.

Mr. March: It is a rejected part of the proceedings.

Trial Examiner: It is a rejected exhibit but it is transmitted to the Secretary as a part of the proceeding.

Mr. Keffer: All right. The Examiner will give us an exception, of course.

Trial Examiner: Surely.

Exhibit 315 is as follows:

Exhibit No. 315

Written Statement of

C. Don Hughes

During my cross-examination in these proceedings in connection with my testimony presented on pages 14455 to 14461, inclusive, of the record, I stated that I was watching the performance of the Texas Panhandle Field and studying the matter to see if another method (referred to as a pressure squared method) which I described in my testimony was actually working in the field and would solve the difficulties arising in the attempts to apply the so-called pressure decline method to the problem of estimating reserves of the field. I stated further that my observations indicated that the field was working as this pressure squared method indicated it should be and that therefore the remaining reserves in the field might vary directly as the square of the remaining pressure at the time rather than according to the commonly accepted method involving variation directly proportional to the pressure. I have been requested by counsel for Canadian River Gas Company to prepare this statement in further explanation of the study mentioned above and the conclusions reached therefrom.

Additional study and investigation since the date of my cross-examination has revealed to me that the method of

estimating gas reserves in the Panhandle Field, based on the squared pressure relationship, produces more consistent results than any other known method. The truth of this statement is strikingly demonstrated when pressure squares at different periods are plotted against cumulative production for such periods, and the straight line is drawn which most closely represents the observed data.

There is attached hereto Chart I on which the squares of the weighted average pressures of the field for the mid-year tests of 1935, 1936, 1937, 1938 and 1940 are plotted against the cumulative production of the field for each period from August 1, 1935. This is the period in the history of the field in which the most reliable data for both pressures and production figures have been obtainable. A straight line which most nearly fits the plotted points has been drawn upon the chart, and it may be noted by inspection of the chart that the distances by which the individual points differ from the line are so slight as to be negligible. The fact that a straight line so closely represents the points plotted in this manner indicates that there no doubt is some physical condition existing in the reservoir which is measured by the method of squaring pressures. Because such a straight line is not obtainable by any other method, that physical condition must be distorting the results obtained by applying the usual volumetric method, and results obtained from the latter method must be inaccurate and unuseable.

One explanation of the existing physical condition, which would indicate that the pressure squared method is properly measuring its effect in this case, has been advanced by Dr. Stanley C. Herold, a petroleum geologist and production engineer formerly associated with Stanford University, in his book entitled "Analytical Principles of the Production of Oil, Gas and Water from Wells" (Stanford University Press, 1928). Dr. Herold's publication relates that he had observed this same difficulty in using data available to measure reserves a number of years ago, and discovered that Jamin had done considerable research in France about 1860 on the flow of gas through capillary tubes which contained small globules of water; that Jamin had set out certain laws concerning the behavior of gas flow under these conditions. Dr. Herold applied these laws by mathematical analysis

to the problem of gas reservoirs, and his study indicates that if a reservoir fulfills the necessary qualifications for capillarity to affect the flow of gas from the reservoir, the relation between gas withdrawals and squared pressures must be a straight line. In our case we secure the straight line from plotting the results of withdrawals in the field and it is not unreasonable to assume that physical conditions in the Panhandle Field do fall within the classification which Dr. Herold defines.

The projection of the straight line on Chart I to the production axis indicates that there was a remaining reserve of approximately 12.6 trillion cubic feet at 16.4# pressure base down to 0# well-head gauge pressure as of August 1, 1935.

The question as to what production prior to August 1, 1935, would have caused a reduction from virgin pressure of 430# to the pressure in 1935 is answered by the straight line, extended backward and up to the ordinate value of 184,900 (the square of 430) where it indicates prior withdrawals of approximately 5.1 trillion cubic feet. This amount differs by only 2% from the 5.2 trillion shown by Mr. C. J. Peterson's production tables, which were obtained by accumulating all available production data and estimating gas withdrawals where they were known to exist but for which no measurement data were obtainable. This would indicate that the withdrawal figures commonly accepted by the industry and the Railroad Commission of Texas for production of gas prior to standardization of measurement basis in 1935 are reasonably correct.

Chart I shows that the total original reserves in the Texas Panhandle Field were approximately 17.7 trillion cubic feet, which is the sum of production prior to August 1, 1935 (5.1 trillion) and the indicated reserves remaining at August 1, 1935 (12.6 trillion).

Table I below is a tabulation of the data from which Chart I was plotted.

Table I

Basic Data

Date	Weighted Average Well-Head Pressure R.R.C.*	Weighted Average Well-Head Pressure Squared	Cumulative Production from 8-1-35 MCF at 16.4 # Base
8-1-35	362.51	131,414	0
7-1-36	355.00	126,025	556,485,654
7-1-37	347.05	120,444	1,109,367,056
8-1-38	337.66	114,014	1,732,292,217
8-1-40	318.31	101,321	2,884,710,964

*The weighted average pressures are the computations of the Railroad Commission of Texas.

The record reflects the following with respect to additional testimony at Washington:

Mr. Lange: Mr. Examiner, there has heretofore been filed in this proceeding by the Colorado Interstate Gas Company an application for the taking of some depositions in this proceedings. Commission's counsel has been advised by general counsel that it is the Commission's desire that instead of having a deposition taken or depositions taken in the proceedings that it be suggested to the Examiner that at the time the proceedings here are concluded the Examiner will recess the proceeding to be resumed in Washington, D. C. for the purpose of taking those depositions or taking the testimony of those witnesses in Washington, D. C., rather than having to take the depositions. Commission's counsel, therefore, at this time would suggest to the Examiner that instead of taking depositions in the proceedings at Washington, D. C., that this proceedings be recessed to be subsequently resumed in Washington, D. C., for the purpose of taking the testimony of the witnesses named in the application.

In that respect, in order to expedite the final conclusion of this proceedings, we would suggest that the resumption of the hearing be had in Washington, D. C. at the earliest possible date and also that the proceedings there be confined to the taking of the testimony as applied for by the company.

The Trial Examiner: I think with respect to the practicalness of adjourning this hearing to Washington in order to take the testimony of Mr. Lerch and Mr. Payne it is much more practical to do that than to attempt to take their depositions. The Examiner will be inclined to follow that request of Commission's counsel; however, I am wondering, Mr. Brock, what the thoughts of respondents are with regard to the time that will be necessary to get ready to take this further testimony.

Mr. Brock: Mr. Examiner, of course we are breaking up here after five months—after a five-months' session—and apparently everybody will need a little time to get home and look around and perhaps take care of a few personal matters. Mr. Spencer and Mr. Dougherty and some of the rest of us have talked about it before and it was their suggestion that we reconvene April 28th. It was thought there would be no serious delay if that much time were taken.

There is one other thing I want to say, too, Mr. Examiner, in connection with Mr. Lange's last remark. I haven't understood in connection with this future hearing in Washington the thing was to be strictly limited to the testimony of the witnesses whose depositions we had applied to take. I haven't discussed that as fully with Mr. Dougherty and Mr. Spencer as I might have done, but my understanding was—I know Mr. Lusk has referred several times to some allocations or separations of an exhibit which he was interested in, and Mr. Rhodes has given attention to that particular study but didn't get it completed when he left here on account of illness and went to Florida. After coming back from Florida, my advice is that he has been very much engaged in some more natural gas cases before the Federal Power Commission, I believe, and the result is that I have had in mind all the time that would be possible; that it would be possible to introduce such an exhibit back there at the Washington hearing and possibly anything else anybody might have overlooked in this long five-months' hearing here in Denver.

I don't mean by that that either side should reopen this case and start trying it all over again, but there is a possibility of a mishap on either side on some particular item

Mr. March: If the Examiner please, the Commission's counsel's position is that we shouldn't wait until April 28th to reconvene in Washington. That would be four weeks' time and we should reconvene in two weeks, or a shorter length of time. If we wait to reconvene at Washington until that late date, this hearing will be going on June 1st and it seems we should not do that.

In the second place, we object to any testimony in Washington other than the testimony specified in the application of the parties which counsel signed. Our purpose has been to finish this hearing. If we go to Washington and leave this exhibit and that exhibit and this witness and that witness coming up, we will be trying this case all summer, and we most strenuously object. We object to any such a construction or arrangement to be made. There have been certain specific reservations made here.

Mr. Brock: I would like to make a reservation—

Mr. March: We object to that most strenuously. It is a thing we have been fighting to do, to get through with this hearing. This thing can run on and on and on and on as so many hearings have done with appreciable results.

Mr. Brock: I submit, Mr. Examiner, on each side here after this long drawn-out hearing, not having had an opportunity to review what evidence has gone in in detail, that it would be beneficial to keep the case open should either side discover something which ought to really go in. It wouldn't be surprising if something has been overlooked on either side and I don't think there is any such grand rush as Mr. March has been talking about.

The Trial Examiner: Let me say this: First of all, as to the date we might reconvene this hearing, the Examiner is going to be tied up in another hearing commencing in Washington on April 2nd. I have no thought at present as to how long that hearing might last, so I am reluctant to trim this time too closely.

In addition to that, the Examiner must insist that the record in this proceeding be corrected up to date and the stipulations submitted to the Examiner with regard to corrections of the record the day we reconvene in Washington.

Counsel are considerably behind in making corections of the record and that may require some time.

I had in mind, frankly, Mr. Brock, meeting somewhere around the middle of April.

Mr. Brock: We might consider the 21st which is the Monday preceding the date I suggested as the earliest date.

The Trial Examiner: Let me do this: I will set the time as April 21st, 1941, and then in the event the Examiner should not be free at that time or some other emergency arises, then we can make different arrangements at that time.

Mr. Brock: It is satisfactory to try it that way.

The Trial Examiner: The Examiner will set April 21st, 1941 as the date.

Now, with respect to the purpose of proceeding back there, the Examiner feels that the proceeding should be directed to the purpose of taking the testimony of Mr. Lerch and Mr. Payne; however, the Examiner is fully cognizant of things that are sometimes overlooked in continuing a hearing as many days as we have in this case.

While at this time the Examiner feels that proceeding back there should be for the specific purpose of taking the testimony of Mr. Lerch and Mr. Payne, nevertheless, the Examiner is perfectly willing to consider at that time the merits of additional testimony of either counsel for the respondents or Commission's counsel might have and to consider the offering of that testimony at that time rather than to attempt to leave the hearing wide open, so to speak, without some definite purpose on the adjournment to Washington.

Hughes also testified (Vol. 95, pp. 14528; 14569-14570; 14582-14594; 14623-14626) as follows:

Q. Is this the first time you have ever made any study of the Canadian River wells?

A. Of the Canadian River wells?

Q. That's right.

A. Well, I think that the information that I have shown

you shows, even if I had only read this information, it would show that I have made a study of the Canadian River wells.

* * * * *

Q. Did you ever think about checking your alleged drainage by the actual conditions that existed in Canadian River acreage prior to 1932 and in the west part of the field prior to 1932?

A. No, I made no study prior to 1932 of the type that I have shown here.

Q. Then how do you know that gas was not draining to the Canadian River acreage at that time in 1932?

A. It might have been. My interpretation is that it has not, due to the values that I have assigned. Now, if at 1932 some of this total production that the Canadian River had produced at that date of 94.4 billion, if none of that—I mean if they had lost no gas in addition to that by drainage, then my study would become a definite indication that my factor .919 is too large.

Q. Too large?

A. And then I would apply a lower factor to all those Canadian River leases and it would end up with a less estimate of reserves on the basis that they had obtained from their own leases, every foot of gas at that date, and if you assume that they had obtained more than some of their own gas, it would still further reduce this factor basis, which then in the end would wind up that I would come out with an estimate of reserves that is smaller than the one that I do come out with in this study. That is the only conclusion that could follow. Now, whether that is actually the case or not, I don't know for sure, but it is my interpretation that the conditions as I have shown in this statement on Canadian River reserves is the basis—is the best possible conclusion that I arrive at.

* * * * *

Q. Mr. Hughes, have you made a study by years of the pressure declines of Canadian River's acreage and the production of Canadian River's production as a whole by years all the way through to ascertain as to whether there has been any drainage from the area?

A. No, not the way you have described it. I have made a study, that is, I made a study in the middle of 1932, the

middle of 1938 and the middle of 1939, and the results are shown here.

Q. Mr. Hughes, you have here a figure for August 1, 1938 as of that date—it is a drainage figure, which you say has been drained away from Canadian River acreage, it being the difference between your production and depletion figure. Why did you skip those intervening years?

A. I don't know. It was really of no importance. One reason I went back to 1932 is that it was my opinion, generally speaking, the production from Canadian River acreage at that date accounted for the pressure loss, so the study for that date was for the purpose of trying to test the reasonableness of my factor.

If I had come out with a much greater apparent loss by drainage, I would have been inclined to think my factor was wrong. If I had come out with an apparent drainage into the Canadian River acreage at that date, I would have again concluded my factor was wrong. But since it came out so close, I considered it a good check on my factor. The reason I used 1938 and 1939 was that I wanted to make a test of what was going on currently. Those were the last two years I had at my disposal, and knowing that the production was shifting over into that general area from other parts of the field, I wanted to test the current performance. A year was a handy period to *chose* because the tests were made from one year to the next.

From 1938 to 1939 was the most recent year and naturally I wanted to make the test in the light and effect of the shifting of production into that area. That is the reason.

Q. I see here in 1938 and 1939 you tried to measure in percentage the drainage which has taken place from Canadian River's acreage.

A. I tried to measure—I obtained a percentage figure which represents the difference between depletion; that is, the amount of depletion which Canadian River produced.

Q. I gather you disagree wth Mr. Gill in that you think you can measure drainage quantitatively from the Canadian River?

A. That is what I attempted to do.

Q. Did you hear Mr. Gill's testimony that he couldn't do it quantitatively?

A. I don't know that he said that. I heard his testimony.

Q. On Page 11 of his written statement—

Mr. Spencer: Which exhibit is it, Mr. March?

Mr. March: Exhibit No. 266.

He states: 'Since the original per acre reserves varied widely as between different parts of the area, such a quantative calculation cannot be made from the figures given on the table."

The Witness: What table is he talking about?

By Mr. March:

Q. The previous paragraph: "The figures arrived at in both of the above studies reflect the effects both of drainage and of original difference in reservoir content. If it could be assumed that the original reservoir content expressed in terms of total gas per acre was the same in all parts of the field, these figures could be used to obtain a quantitative expression of the drainage that had occurred into and out of the zones of pressure loss up to the time when the study was made."

A. Is he talking about Canadian River acreage?

Q. Yes. Didn't you hear his testimony?

A. Yes. He is apparently talking about Mr. Hammer's quadrants. I don't think what you were reading had anything to do with the question you asked me.

Q. Is that so. So you don't think Mr. Gill stated that he couldn't measure drainage quantitatively? Is that your position?

A. With respect to Canadian River acreage?

Q. That is right.

A. You haven't shown me where he did.

Q. All right, sir. I just wanted to get your position.

You state here that approximately 27 per cent was drained away between 1932 and 1938, is that correct?

A. No, that—

Q. That is the last year.

A. The percentage figure you are reading there—I think you will find that refers to the percentage of the depletion of Canadian River leases from the beginning of the field to the date 1938.

Q. How much gas has been drained away from Canadian River acreage between 1932 and 1938 according to your contention?

A. I don't know. I don't know that it is figured here.

Q. Have you made such a calculation?

A. No, but we can do it. It would be the difference between—from these figures on Page 3 you could determine that.

Q. What is the amount of difference between the depletion and production? What would be the amount drained away from 1932 to 1938?

A. Now, what was it you wanted—the percentage?

Q. I want to know the amount of gas in Mcf. which has been drained away according to your figures from Canadian River acreage from 1932 to 1938.

A. I have gone through the arithmetic and unless I have made a mistake, it is 29,821,939 cubic feet.

Q. Which has been draining away?

A. Between July 1, 1932 and August 1, 1938.

Q. And as we found out a few minutes ago, your figures showed that approximately 21 million Mcf. had been drained away prior to 1932?

A. Yes, that's right.

Q. All right, Mr. Hughes, how do you account for the fact that if 21 million had been drained away prior to 1932 that only 29 million according to your figures were drained away from 1932 to 1938, during the most prolific production of the field?

Mr. Spencer: Are you saying millions or billions, Mr. March? I believe you said millions.

Mr. March: Yes?

Q. Is this 29 figure in millions of Mcf.?

A. It is in millions of Mcf. It is billions of cubic feet —29.8 billions of cubic feet.

Q. Is that the same unit we used when we measured the 21 million prior to 1935?

A. Of Mcf., that's right.

Q. How do you account for the fact that whereas with very few wells adjoining Canadian River, if any, prior to 1932, 21 million was drained away and with a great deal of production around Canadian River acreage since 1932 only

29 million according to your figure has been drained away?

A. I don't know how to account for it. That's just the situation. That's just the way it works out.

Q. Now, Mr. Hughes, you come here to the map and show me where that 29 million went to that drained away from 1932 to 1938.

Mr. Spencer: He doesn't have to come to the map to show you that.

Mr. March: Well, anywhere. I don't care.

The Witness: Well, it will be going to areas of lower pressure than the pressures from which it was drained, wherever those lower pressures exist, that's where it would be going.

By Mr. March:

Q. All right, now, what part of the Canadian River acreage was drained during that period? It couldn't have been drained, could it?

A. All of the Canadian River acreage being drained?

Q. Could all of the acreage have been drained during that period?

A. Do you mean that that drainage was uniform from acreage scattered over the—

Q. No, I mean, could all of the acreage have been drained during that period—some gas out of it?

A. Well, it would depend upon the pressure pattern in the acreage. This is an overall figure. This is the net result of their drainage. Now, the drainage had to be going in that direction of lower pressured areas than the pressures in the Canadian River acreage. I think that is obvious. Now, just where those particular areas were generally speaking, they are in a northeast direction from the Canadian River group.

Q. Now, come up here on the map and show me approximately where that Canadian River gas was going specifically.

Mr. Spencer: Do you want to refer to Mr. Dunlap's map?

The Witness: Well, those I think would be sufficiently—they are sufficient to indicate where the low pressure areas are. Due to the fact that the yellow is the highest pressure

color on this set of maps, Exhibit No. 239, then the orange is the next lowest group and the next lowest group is the blue and the green—by the time you get out the green you are getting out pretty close to the edge of the Canadian River area as a group of leases that I am talking about. What I am talking about Canadian River group of leases, I am referring to this group of colored leases here on Exhibit 95.

Now, by 1938 the green area is the area that is approximately less in pressure than all of the rest of the Canadian River area. Therefore, the Canadian River group of leases as a group, the drainage would be from then out in that direction. It would be in the direction from the Canadian River group of leases of southwest Hutchinson County.

Q. Drainage through southwestern Hutchinson County?

A. No, it would be draining into the area of southwest Hutchinson County.

Q. The green area?

A. Shown in that green color, the travel of gas being from the blue area into the green area and from that orange-colored area into the blue and from the yellow area into the orange. Now, that is the general—the only conclusion that you can make from the pressure setup.

Q. Now, Mr. Hughes, I have already asked you about 1933, about whether or not you could tell me whether or not those pressures were caused—the declines were caused by drainage there in the southwestern part of Hutchinson County or by production. I will now refer you to the 1934 map.

Mr. Hughes, you see that portion where it shows 400 to 350 pound pressures there extends over for the first time over into the corner of Potter County from Hutchinson and over into some of the Canadian River acreage in Moore County.

Now, I will ask you this question; whether or not the declines in pressure there during that year period was caused by production from Canadian River wells within the area or whether or not that was caused by drainage.

A. In my opinion it was caused by both.

Q. Have you made a study of the production of the individual wells in that zone?

A. No, not of the individual wells.

Q. Have you made a study of the production from the Canadian River wells as a whole in that zone during that period?

A. No, I hayen't, and I don't think it would be possible to arrive at a conclusion—a conclusive opinion from such a study, since the pressure contours indicate that drainage is going on. Then, the production from wells in that area of course influence the reduction in pressure but the actual total reduction in pressure in the area is a result of both the production from wells in the area and the drainage from the area.

Q. How can you state that it is when you haven't made a study of the production decline in the entire year period of time?

A. Well, I thought I made it clear.

Mr. Spencer: He has answered that question, Mr. March.

Mr. March: You mean by stating that his exhibit shows it?

Mr. Spencer: He said such a study wouldn't show you anything.

Mr. March: Well, he never made a study. He doesn't know whether it would show anything or not.

Q. Now Mr. Hughes, you see the 1935 map. You see there is, in Mr. Dunlap's map there, there is a slight intrusion—a little further intrusion of the brown 400 to 350 pound zone over to Potter county?

A. Yes.

Q. And there is a still further movement of the zone over into Moore County, Canadian River acreage?

A. Yes.

Q. Now I will ask you the same question—if I would ask you the same questions relative to the movement of those presures back as I did to the previous 1934 map, would your answers be the same?

A. Yes, that that pressure condition is due to both production from wells in the area and drainage of gas from the area, yes that's right.

Q. And that you have not made any study relative to the

production of the individual wells in the area during the period of the pressure decline of that period, or the total production from those wells?

A. For that period?

Q. That's right.

A. No.

Q. Now, next we come to 1936 and we find that the brown area which is 400 pounds, has intruded a little farther into Potter County, down into Potter County.

A. Yes.

Q. Now, if I should ask you the same questions in regard to that that I asked you in regard to the previous ones, would your answers be the same?

A. To the area as a whole?

Q. Yes, sir.

A. That the effect of those pressures is due to both production from wells in the area and drainage from the area?

Q. Yes.

A. Underground drainage from the area?

Q. Yes.

A. Yes.

Q. And have you made a study of the individual wells in that area during the periods of pressure declines by years, or the production from the wells as a whole in that area during that period?

A. No, I haven't made that study.

Q. Now, Mr. Hughes, we come to 1937 and I note here that there is some change in the configuration of the 400-pound pressure in Potter County and that there is a further intrusion into Moore County of the lower pressure area, but I note with a great deal of interest here that in the western part of Potter County that the pressures have increased back clear over the Potter County line into Moore County and that low pressure area has been wiped out in Potter County.

Now, that indicates that during that period, doesn't it, that the pressure has increased in Potter County in that area?

A. That is my interpretation, and that is why I mentioned a while ago in connection with the 1936 map that if you meant from the area as a whole. I recognized that

little extension that is sticking back in there into north Potter County on the 1936 map. It is obvious from the 1937 map that that little area that stuck back into there was repressured. At least it is so indicated by the contouring on the 1937 map.

Q. Now, do you think that is a correct delineation of what has happened from your studies?

A. Yes, definitely. Again, the effect of that pressure is due to the combination of production and drainage. In that particular case it would be my conclusion that the production during that particular time wasn't quite as great as the drainage was into the area, and, therefore, the pressures built up, assuming those are correct pressures. We are assuming that those were the correct pressures and the maps were made correctly, and I have no reason to doubt either one. I am just telling you what was involved.

Q. Have you made a study of the production in that area by years in 1937 of the pressure increases of the individual wells or decreases?

A. No, I have not.

Q. Now, Mr. Hughes, you would have to show a gain in pressure and reserves of Canadian River Gas Company in 1937, wouldn't you, if you had it done on a yearly basis?

A. Yes.

Q. You would?

A. Yes, the pressures came up. I think you will find there are some examples of that in the study that you have marked Exhibit 280. If the pressures have come up, naturally, over the previous period, when you treat that particular tract, that very treatment of it shows that that tract had gained a little.

Mr. Spencer: You are talking about tracts or the whole Canadian River area?

The Witness: Tracts, I was thinking of there.

* * * * *

Q. Oh, yes, I challenge you to show me one well up here to which gas has moved away from the Canadian River Gas Company in 1939.

Mr. Spencer: Now, Mr. Examiner,—

Mr. March: As distinguished from this—these other years.

Mr. Spencer: Here I am on my feet again. I don't see why it is necessary for counsel to challenge anybody here. If he wants him to point out a well, if he knows, then that's all right.

Mr. March: I'm sorry I said "challenge."

The Trial Examiner: This is up to 1939?

Mr. March: That's right.

The Witness: The year ending 1939?

By Mr. March:

Q. Ending July 1, 1939.

A. Mr. March, in order to pick out a particular well that could have obtained, and in my opinion would have obtained some of the gas that was lost by leases owned by the Canadian River acreage during the year ending 1939, I could construct for you on Mr. Thompson's contour map a little geometric pattern going down his pressure contours at right angles to those contours in such a way that the arrangement of the area between one limit of this area and the other limit would be the expanse of the Canadian River acreage and I would merely follow on down his map by going at right angles to his contours to where that method going from one contour to the next would finally bring me in to the lowest pressure in the pattern.

Now, then, to be specific, I would go to the Railroad Commission and get a list of each well in that area whose pressures were lower than the Canadian River leases and each well in that area that had produced a cubic foot of gas in that year ending in 1939. I would list in that list not only one well for you but I would give you the whole list that in my opinion would include the wells that in my opinion were getting some of the gas that started from the Canadian River leases during that year.

Now, just how far out, as you go down-dip in a pressure manner, the particular gas that left Canadian River leases during that period had extended by the end of the year, I wouldn't attempt to say, but sooner or later those would be the wells that would eventually get some of the gas, or at least some of the gas that was being replaced by gas that had started from back up there in the Canadian River leases.

Q. Mr. Hughes, you have never made such a study, have you?

A. I never have made such a study?

Q. Yes.

A. No, I haven't.

Q. Now, Mr. Hughes, you criticised Mr. Hammer because his production declines—I mean, his production pressure figures you said would not approach a straight line, but have a downward trend. Now, would your figures approach a straight line for the pressure decline method that you have utilized?

A. How do you mean that I have utilized—on the tract-by-tract—

Q. No—yes—in other words, you have an estimate in which you use a pressure decline method at 7-1-32, 8-1-38, and 8-1-39,

A. Well, the way I have applied Boyle's Law in each tract, I am assuming that it is a straight line. Now, you were confusing—I have not applied the pressure decline method in this study. I started out with my estimate of original content in each tract and I applied Boyle's Law and found the computed amount of gas that was lost by all the tracts and made a comparison to that figure of production that had been taken from those tracts. The thing that you have tried to ask me to compare, I don't think is comparable. I haven't said that Boyle's Law wasn't working in the field. I said the pressure decline method applied to the field is not working. I have assumed that Boyle's Law is working, but as I have explained before, I am not so sure now that we know correctly just which manner we should apply Boyle's law.

Testimony of STANLEY GILL, Witness for Canadian

Necessity for a Correct Equilibrium Pressure

Stanley Gill, whose qualifications have heretofore been given, testified with respect to the several estimates of reserves introduced in this case and particularly with reference to the pressure-decline method as applied to the Texas Panhandle Field and the absolute necessity of having a correct equilibrium pressure before this method can be ap-

plied. His testimony on direct examination is contained in his written statement in Volume XCI, pp. 13981-13998, and in Exhibit 265, pages 5 to 18. The following is a statement of Gill's testimony.

"The several estimates of reserves made in this case were subjected to careful scrutiny and study. Attention has been given to the correctness of methods employed, to the manner in which they have been applied and to the applicability of the results in determining the future producing life of gas reserves in the Texas Panhandle Field. Witness analyzed these methods from the point of view of engineering fundamentals and also on the basis of his own knowledge of the Texas Panhandle Field.

While it must be understood that estimation of reserves of gas or oil is far from being an exact science, it must also be emphasized that reasonably accurate estimates can be arrived at by the application of proper methods. Such estimates are frequently used as the basis for very large transactions and expenditures. In such cases large sums of money may depend upon the validity of these estimates and accuracy is of the utmost importance.

The accuracy of an estimate of reserves of oil or gas depends upon the completeness and dependability of the basic data, upon the correctness of the methods of estimation and their application and upon the reliability and experience of the geologist or engineer by whom the estimate is made. Probably the most important of these is the experience of the individual who makes the estimates. Purely mechanical application of a procedure of estimation may be made by a raw and inexperienced graduate of a good technical school. Such an estimate, even though it be couched in highly technical terms and accompanied by maps and mathematical formulae, is usually quite valueless and would never be acceptable as a basis for purchase or sale of properties, for valuation as collateral for a loan or for determination of the advisability of large expenditures in operating facilities. Proper estimation of reserves requires not merely a knowledge of the mechanics of an estimating procedure, but also a critical faculty that can be gained only through many years of detailed experience. While witness is not prepared to go as far as a certain eminent geologist who once stated

that "geological instinct" was the only reliable guide to estimation of reserves, he is very definitely convinced that detailed familiarity with a producing area and a thorough background of experience in estimation of reserves are of vital importance if dependable results are to be obtained. The results are "estimates" rather than "determinations" of the reserves of oil or gas. The results arrived at cannot be exact, but they are dependable and can be weighed and compared by careful and critical scrutiny of the procedures by which the results were obtained.

Hammer, Commission witness, has made his estimate of reserves of gas in the Texas Panhandle Field by a pressure-decline method which involves several unique features. Witness is of the opinion that Hammer's estimates are neither correct nor applicable for evaluating the probable future life of the Canadian or field reserves. This opinion is based upon three lines of reasoning:

(a) A pressure-decline method in which withdrawals of gas are compared to declines of pressure, the latter being weighted only on surface acreages, is entirely incorrect for estimation of reserves of gas in the Texas Panhandle Field;

(b) Even if a method of this type could be correctly applied in the Texas Panhandle Field, Hammer's procedure would lead to entirely incorrect results. The weighted procedure used by him results in incorrect conclusions as to pressure-decline relationships for the field as a whole and is erroneous in its application to Canadian's acreage; and

(c) Hammer's estimate of remaining gas reserves under Canadian's acreage would be without value in the prediction of future producing life of this acreage, even if it were correct, since it fails completely to take into account the effects of future drainage.

There can be no doubt of the fact that pressure-decline methods, where they are properly applicable, afford an accurate means of evaluating reserves of natural gas. Where the data on a field are adequate for such an estimate, and where these data show that the pressure-decline method can be properly applied, the estimates of reserves and ultimate

recoveries are more accurate than can be attained by other procedures of estimation. For this reason, pressure-decline methods should be preferred to others for estimation of gas reserves in those fields to which such methods can be properly applied. In many fields, however, physical conditions are such that pressure-decline estimates may lead to widely erroneous conclusions. Indiscriminate and unreasoning application of pressure-decline methods, without careful study of their adaptability for the estimate being made, may lead to false results and conclusions.

Figure 1, attached to Exhibit 265, shows typical relationships between pressure-decline and accumulated total production and production per acre-pound in various types of gas reservoirs. Obviously, reserves can be calculated from pressure-decline only in those cases where pressure declines directly with production, or where the departure from direct variation is accounted for by deviation from Boyle's Law.

Gill further testified on direct examination that a straight line relationship cannot be applied for proper and correct estimation of reserves where the facts on a field, when plotted in curves such as those of Figure 1, Exhibit 265, do not conform to Boyle's Law.

The Texas Panhandle Field is definitely a field to which simple pressure-decline methods, invoiving weightings on surface acreage alone, cannot be properly applied. The theoretical reasons for this are elementary. Fundamentally, application of the gas laws and particularly of Boyle's Law, which expresses the relationship of gas volumes to pressures, are related entirely to volumes and not at all to areas alone.

Boyle's Law expresses a simple relationship. It states the fact that the quantity of gas contained within a rigid container varies directly with the absolute pressure. Doubling the pressure doubles the quantity of gas. By increasing the pressure ten times, ten times the quantity of gas can be stored within the container. Quantity, as thus applied, of course, means the actual weight of gas or the equivalent volume of gas at some definite base temperature and pressure. This law applies strictly to any perfect gas, regardless of the size or shape of the rigid container in which it is confined. Correct calculations can be made from it, however,

only when the actual pressure averaged throughout the entire volume of the container is accurately known.

The true weighted average pressure of gas in the Texas Panhandle Reservoir cannot possibly be determined, however, by weighting pressures against surface acreage alone. The reason for this is shown by Figure 2 attached to Exhibit 265, which is a reproduction of a drawing witness prepared in 1935. The top sketch on this page is a cross-section of the gas producing formation across the Texas Panhandle Field. The basic cross-section was prepared by C. J. Peterson from logs of actual wells. In the second drawing the distribution of original gas reserve across this cross-section is shown. The very great variation of gas content for equal surface acreages is apparent. In the third sketch an equivalent distribution of this gas in containers is shown. Each of these containers represents, in size, the volume of gas which originally underlaid an exactly equal surface area.

The true average pressure throughout the entire volume of gas in any gas reservoir can be correctly determined by weighting on surface acreage alone only under either of two sets of physical conditions. These are:

(a) When the pressure is equal in all parts of the reservoir; or

(b) When each and every acre in the reservoir is underlaid by exactly the same volume of gas-bearing voids.

When one of these two conditions exists the actual pressure existing through the volume of gas within the reservoir can be determined from a consideration of surface pressures and surface acreages, but this cannot be done under any other conceivable set of physical conditions. Since neither of these conditions exists, nor is even barely approached, in the Texas Panhandle Field, determination of average pressures by weighting on surface acreage alone cannot possibly lead to an evaluation of the actual average pressure existing through the volume of remaining gas, and therefore cannot possibly lead to a correct estimation of the gas reserves of the reservoir or any part of the reservoir.

The fact that the pressure-decline method, using pressures weighted on surface acreage alone, cannot be applied to the

Texas Panhandle Field, is conclusively demonstrated not only by unquestionable theoretical considerations, but also by all of the available factual data on relationships between pressure-decline and production of gas in the field. If surface pressure weighted on acreage alone could be correctly applied to estimation of reserves of gas in the Texas Panhandle Field, the yield of gas for any given increment of average pressure would always be equal. This is absolutely fundamental. Neglecting corrections for deviation from the gas laws (which are well known and which can be applied to any given case) the amount of gas remaining in any gas reservoir of constant volume, will be strictly and exactly proportional to the average absolute pressure existing through the volume of gas in the reservoir. If the volume of the gas-filled space changes, as for example in a field in which there is rapid water encroachment, this proportionality will not exist and pressure-decline estimates can be applied only by correcting for the changes in reservoir volume. This is not necessary in the case of the Texas Panhandle Field, where water encroachment is of such a minor character that its effect on reservoir volume can be entirely ignored. For such a reservoir the remaining quantity of gas, expressed in weight or in volume at a given base pressure, will necessarily and inevitably be exactly proportional to the actual average absolute reservoir pressure.

In the Texas Panhandle Field the original reservoir pressure was approximately 471 pounds absolute. When the actual average pressure throughout the volume of gas in the reservoir has declined by 25% to 353.3 pounds absolute, exactly one-fourth of the volume of gas which originally existed within the reservoir will have been removed. When it has declined 50%, to 235.5 pounds absolute, exactly one-half of the original gas will have been withdrawn from the reservoir. In other words, each decline of one pound per square inch in the actual average absolute reservoir pressure will be brought about by withdrawal of exactly 1/471st of the quantity of gas that originally occupied the reservoir voids. If this strict and exact equality of pressure-decline for equal volumes of gas withdrawal does not exist, it means either that the volume of the reservoir does not remain constant or that an attempt is being made to apply improper

gas withdrawal figures or incorrectly calculated average pressures.

(Note: Both Hughes and Hammer have used wellhead pressures which are 430 pounds.)

The lack of proportionality between gas withdrawals and pressure declines results almost entirely from incorrect pressure-decline figures. Massa and Hughes have submitted calculations based on Hammer's pressure and production figures. Their calculations show that the yield of gas per acre-pound or per pound decline in pressure has decreased progressively from year to year during the period covered by Hammer's estimates. The results arrived at by Massa and Hughes are shown in Exhibit No. 257 and Exhibit No. 258, respectively. This progressive decrease from year to year shows conclusively that Hammer's application of a pressure-decline method is totally incorrect and leads to an entirely false estimate of gas reserves. Hammer is not alone in this error. The same fallacy exists and can be conclusively shown to exist in any other estimate of gas reserves of the Texas Panhandle Field, based on declines of average pressures arrived at by weighting on surface acreage alone.

Hammer has overriden and ignored the lack of uniform relationship between pressure-decline and gas withdrawals by adopting as his fundamental premise the assumption that the curve expressing relationship between average pressures and accumulated total gas withdrawal is a straight line. He has, therefore, by application of an averaging procedure based on the method of least squares, drawn his curves as straight lines, or has applied an average yield per acre-pound per square inch derived from such calculations. His error is in incorrectly assuming a straight line relationship between pressure and accumulated total production. This relationship does not in fact exist between pressures, averaged by weighting on acreage alone, and accumulated total withdrawals in the Panhandle Reservoir. An actual plotting of Hammer's own figures connecting the points as he has determined them, demonstrates the fact that yield of gas for equal increments of pressure-decline are progressively less from year to year on the basis of average pressures calculated as he has calculated them.

The fact that the pressure-production relationships employed by Hammer in making his estimates do not come close to conforming to Boyle's Law, is proven by a consideration of the data contained in Table III of his Exhibit No. 180. In Figure 3, attached to Exhibit 265, curves of pressure against production, accumulated from August 1, 1935, are plotted from Hammer's results by "quadrants," as given in Exhibit No. 180. It is obvious that none of these is a straight line relationship, and that the application of Boyle's Law is improper. The great error resulting from Hammer's application of Boyle's Law is even more apparent from Figure 4 attached to Exhibit 265. In this figure, the variation in rates of recovery, per acre-pound, are plotted by "quadrants." If Boyle's Law applied, these would be horizontal straight lines. The actual uniform tendency, as shown in Figure 4, is such that application of Boyle's Law results in a gross over-estimation of reserves.

Hammer assumed that his pressure averages correctly expressed performance in accordance with the gas laws, when compared to gas withdrawals. On the basis of this premise he assumed that the relationship between these two factors should be a straight line. He therefore constructed straight lines by the application of a mathematical method which could, in fact, lead to the construction of a straight line to represent the distribution of bird shot in a shot gun pattern, but which leads in the application which he has made of it, to a conclusion which does not bear any reasonable relationship to the actual facts as they exist in the Texas Panhandle Field.

An additional major fallacy is found in Hammer's weighting of his "quadrants." The division of the field into such areas is a legitimate and proper procedure for convenience in measurement and computation. The division could also be used to study the drainage and pressure performance if the subdivisions had been laid out for this purpose. Hammer's "quadrants" are not, however, laid out in relation to pressure patterns, relative reserves or areal distribution of withdrawals. Up to the point of his determination of withdrawals and weighted pressures by "quadrants," Hammer has made legitimate use of his subdivision of the field area. From this point on his calculations based on his

"quadrants" are entirely incorrect. Under the procedure which he has employed, and in which he has combined with each "quadrant" all of the surrounding "quadrants," his results are entirely incorrect as applied either to any particular individual "quadrant" or to any combination of "quadrants," up to and including the complete combination used in arriving at estimates for reserves of the field as a whole. The reasons for these inaccuracies may be simply stated as follows:

(a) The values arrived at for any particular "quadrant" do not and cannot properly express conditions which exist within that particular "quadrant" at the time of the estimates. This statement is obviously true, since the values arrived at are not values for the particular "quadrant" under consideration, but are values for a group of "quadrants," including not only the particular "quadrant" under consideration but also all of the surrounding "quadrants."

(b) For the field as a whole the averages arrived at do not and cannot represent true average values, because unequal weights are given to different parts of the field area. In arriving at the overall averages, Hammer has used some of the centrally located "quadrants" eight or nine times, while some of the edge "quadrants" have been used only four or five times. By his procedure a given area in one of his central "quadrants" may have as much as two times as much weight in the final averages as does an equal area in one of the edge "quadrants."

The unequal weighting would lead to incorrect results, even if all the acreage had been equal in original reserve value, but is even more incorrect for the Texas Panhandle Field because it multiplies the weight given to rich "quadrants" in the center of the structure. This is readily apparent from the cross-section which was shown in Figure 2, Exhibit 265. Averages arrived at by any such procedure as Hammer's are incorrect and give an incorrect and distorted picture when applied to Canadian's acreage. Much of the Canadian acreage is located in "quadrants," the performance of which is inferior to that of adjoining "quadrants" within which Canadian does not hold acreage. By the method of

averaging employed by Hammer, the apparent value of these inferior edge "quadrants" is inflated by the inclusion of performance figures on other areas.

Finally, it may be very definitely stated that an estimate of remaining reserves in place under Canadian acreage as of any date, even though such an estimate were correctly made, would be entirely without value as an indication of the future producing life of such reserves. Such an estimate, expressing only a total quantity of gas in place, fails entirely to consider the effects of drainage, which will actually be of controlling importance in determining the future economic life of these reserves as a source of supply of gas for a trunk pipe line system.

Gill testified on cross examination as follows:

That from the very beginning of his experience in the oil business he was concerned with the problem of estimating reserves. (Vol. XCII, pp. 14070-14072.) That in estimating gas reserves he ordinarily used the pressure-decline and volumetric methods and as to oil, he used the production-decline method. (Vol. XCII, pp. 14081, 14082.) That he had made a number of estimates of reserves on gas fields (Vol. XCII, p. 14100), being fifteen or twenty gas fields in all. (Vol. XCII, p. 14128.) The gas fields concerning which estimates were made were covered in the cross-examination from pages 14085 to 14129.

The witness stated that the use of the term "volumetric" as applied to gas estimates was the method which considered sand thickness and porosity. (Vol. XCII, p. 14101.)

The witness was asked to define "equilibrium pressure." He stated that this was the true weighted average pressure within the formation; that any gas container—gas reservoir—which is inter-connected permeably, would reach an equilibrium pressure if all withdrawals were stopped and if sufficient time were allowed, assuming that there is no water drive and if there were no change in the gas bearing volume. In other words if such a field were shut in long enough it would eventually equalize at a pressure which would be equally the same as the true weighted average pressure.

"Now, that true weighted average pressure which is

identical with what you call the equilibrium pressure, is the only pressure that could be used in a proper application of the pressure-decline method. (Vol. XCII, p. 14113.)

It is the true weighted average pressure (equilibrium pressure) that must be obtained before the pressure-decline method can be accurately applied. (Vol. XCII, pp. 14117, 14118.)

The witness was then asked if volume was not considered when pressures were weighted on surface area. The witness replied that this was not true, although surface is one of the factors in determining volume. He illustrated this by saying that the volume of a carpet covering the floor of a room is not the same as the entire volume of a room, but that is the assumption that is made when pressures in a reservoir are weighted on surface acreage alone.

The witness stated that he had endeavored to make many estimates of gas reserves in the Texas Panhandle Field based upon a proper application of pressure-decline methods and by the utilization of various methods of weighting and various methods of calculation. Each time that he has made such an estimate he weighed that estimate as impartially as he could and has decided in each instance that the estimates were not correct. None of the estimate stood up under his own analysis where he would be willing to accept them. (Vol. XCII, pp. 14140, 14141.) In making such estimates he was not looking for an answer but was looking for a sound method based upon pressure-declines in the Texas Panhandle Field and such estimates as he has made would not stand the test of unbiased engineering criticism; that he had tried hard to make an estimate that he thought was correct because he believes that there is some way of applying correctly the pressure-decline method of estimating gas reserves in the Texas Panhandle Field, but he is certain that it is not an elementary approach. Every elementary approach gives an incorrect result. (Vol. XCII, pp. 14178, 14179.)

He then again referred to Figure 2 attached to Exhibit 265 which is a typical cross-section of the Texas Panhandle Reservoir and which shows the correct deviation in pay

thickness from one side of the field to the other, and explained that this figure showed graphically why it was impossible to secure a true weighted average pressure (equilibrium pressure) by weighting pressures on surface acreage alone. (Vol. XCII, pp. 14156, 14160-14162, 14167.)

Hammer has not arrived at the correct weighted average pressure which most nearly approaches equilibrium pressure because he determines the average pressures weighted on surface acreage alone and the result does not closely approach equilibrium pressure. The witness then reiterated that the curves shown in Figure 4 attached to Exhibit 265 prove absolutely and without any doubt that the pressures utilized by Hammer are not the true weighted average pressures in the Texas Panhandle Reservoir. There is no question in the witness' mind about this. (Vol. XCIII, pp. 14270, 14271, 14273-14275.)

Analysis of Stevens' Method

Testimony of STANLEY GILL, Witness for Canadian

Stanley Gill, witness for Canadian, analyzed the methods and procedure utilized by Stevens, Commission witness. in estimating the recoverable reserves from Canadian's present wells. Stevens' estimate is contained in Commission Exhibit 182. Gill's testimony is contained in Exhibit 265, pp. 18-24, and in Volume XCI, pp. 13999-14006, and is summarized as follows:

The witness stated that Stevens' methods and procedure were entirely fallacious, because:

(a) Stevens estimated reserves by a decline method, by averaging the pressure performance of wells, and this did not truly represent actual average pressures within the reservoir.

(b) Stevens' curves for his individual quadrants were arbitrarily drawn. He did not follow a uniform procedure in averaging out the various points, and did not give the same relative consideration to the points for particular years.

(c) Stevens neglected or ignored his pressure points for 1935 and 1936 in the plotting of his curves, while such pressure points were utilized by Hammer in his estimate. The reasons advanced by Stevens for ignoring the 1935 and 1936 pressure points fall into the category of expediency, rather than sound engineering practice.

(d) Stevens did not construct his curves on the basis of the various pressure points but constructed a straight line that most appealed to his fancy in each particular case.

(e) Stevens arbitrarily assumed that Canadian would continue to produce the same proportion of gas out of each quadrant in the future that it produced in the past. (Exhibits 255, by Hendee, and 256, by Massa, show conclusively that Stevens' assumption is totally unjustified and incorrect.)

(f) Stevens assumed additions to reserves for each additional well completed, and, in doing so, ignored interference between wells and overlapping of drainage areas. This is fundamentally erroneous.

Gill stated further that Stevens' procedure in some cases led to ridiculous results, which is illustrated by his treatment of Potter Quadrant 3 and Potter Quadrant 1. Hammer's estimate of reserves in place in Potter Quadrant 3 was 448,272,000 Mcf. as of August 1, 1939. Stevens estimated that the nine wells in this quadrant, drilled on a spacing of about 3700 acres per well, would recover approximately 525,300,000 Mcf. from the same date, or about 117% more than Hammer's estimate. In contrast to this estimate, Stevens estimated that the twenty-four wells in Potter 1, which are spaced to an average density of about 2400 acres per well, would recover less than 45% of the volume of gas estimated by Hammer as remaining beneath this quadrant on August 1, 1939. Hammer's estimated reserve under this quadrant was 1,282,995,000 Mcf., while Stevens estimated that the existing wells of Canadian and others would recover only 568,800,000 Mcf. Stevens concluded that approximately fifty-two wells, on an average spacing of about 1100 acres per well, would be required to recover the estimated reserves from this quadrant. This would be more than three times the drilled density that Stevens estimated would be required to recover all of the gas, and more, underlying Potter 3.

Gill further stated that another basic error inherent in Stevens' calculations was the assumption that each well produces its gas from a separate and independent drainage area, which Stevens assumed bore a constant and unvarying relationship to withdrawals out of the well. Stevens then assumed that such additional wells will actually increase the ultimate total recovery, unless they are so closely spaced that interference will occur. The witness further stated that interference would actually take place between any two gas wells withdrawing gas from the same permeably inter-connected porous reservoir system. Gill stated that the assumption of Stevens might be correct as applied to oil but was wholly erroneous as applicable to gas.

Gill further stated that given a sufficiently long period of

time, a single well could drain all of the recoverable gas out of any permeably inter-connected porous system, even though the size of the system was as great as that of the Texas Panhandle Field. Additional wells after the first well would not add a cubic foot to the total quantity of gas that could theoretically be recovered out of such completely inter-connected system. Additional wells are drilled, not to add to the reserves, but to make possible recovery of the gas within a shorter period of time.

The drilling program of a gas well is determined by two factors:

(a) The necessity for a sufficient number of wells of sufficient producing ability to supply gas at a daily rate sufficiently high to satisfy the maximum requirements of the available market (peak-load demands). In Texas a well cannot produce more than 25% of its open flow potential, and actually a considerably greater open flow capacity should be developed. Operations to a full 25% of open flow are usually improper and will result in serious operating difficulties. The number of wells should be sufficient to supply the peak-market demands at some considerably lower percentage of total open flow capacity, and there should be additional wells drilled to provide an adequate supply when some wells go off production, which is a normal operating occurrence as wells become older.

(b) In many cases lease obligations, rather than the demands of the gas market, control drilling operations.

Abandonment Pressure in the Texas Panhandle Field

Testimony of MAX K. WATSON, Witness for Canadian

Max K. Watson, gas engineer and assistant general superintendent of Canadian, whose qualifications have heretofore been given, testified as to the rock pressure at which it will become unprofitable for Canadian to continue operating and maintaining its gas wells in the Texas Panhandle Field. His testimony on direct examination is shown in

Volume LXXXVI, pages 13037 to 13045 and Exhibit 254, pages 1 to 7.

(1) The rock pressure at which it will become unprofitable for Canadian to continue operating and maintaining its gas wells in the Texas Panhandle Field.

At 50 pounds rock pressure the back pressure method developed by the United States Bureau of Mines indicates that the average well of the Canadian will have an open flow capacity of approximately 1,000 Mcf. per day as shown by the curve attached to Exhibit 254. By applying the 25% of open flow capacity permitted by the Railroad Commission, the maximum allowable of such well will be 250 Mcf. per day.

A 65% load factor (approximate production load factor for 1940) applied to the maximum allowable will give an average well an average productive expectancy of 160 Mcf. per day, which when valued at 4c per Mcf. at the well amounts to approximately $6.50 per day, or approximately $2,375.00 per year before deductions for royalties and severance taxes amounting to approximately $595.00 per year at present average rates. Therefore, the net amount available for operating and maintaining an average gas well at 50 pounds rock pressure will be $1,780.00. Canadian's cost of operating and maintaining its gas wells in the past without including royalties, severance taxes or amortization charges has been in excess of this amount.

Past and present costs of Canadian for operating and maintaining its producing gas wells do not provide a dependable index for the purpose of measuring the cost of operating and maintaining such wells when they reach rock pressures as low as 50 pounds. Present wells of Canadian have been operating at comparatively high pressures and therefore have been free from many operating difficulties which will develop at lower pressures. As the rock pressure of a well decreases, its open flow decreases at a proportionately higher rate. As the open flow decreases, the well is less capable of keeping itself clean of cavings and free from water, which has a tendency to increase bridging in the hole, flooding and salting in the formation. Moreover, as the wells approach a 50-pound rock pressure, they will be older and the corrosion of casing by water at the forma-

tions in which the well is not producing will become a greater problem. Since a well of low open flow capacity is unable to free itself of its accumulated water, it may be necessary in many instances to pump or syphon off such water which will add substantially to the cost of operating and maintaining the wells.

It should be remembered that when a well reaches a rock pressure of 50 pounds the actual working pressure of such well is only about 40 pounds. It also should be remembered that past tests of the future capacity of a gas well to produce in the Texas Panhandle Field shows that such capacity is declining at a greater rate than is indicated on any specific date by use of the back pressure method referred to above. The fact is that all producing problems have the effect of decreasing a well's ability to deliver gas and causing a corresponding reduction in its producing characteristics as represented by the back pressure curve at any date. Therefore, the estimate given above of the open flow capacity of a well at 50 pounds pressure in the Texas Panhandle Field is a maximum estimate based on present data.

For the reasons above stated, it is his opinion that it will become unprofitable for Canadian to continue operating and maintaining its gas wells in the Texas Panhandle Field when the rock pressures of such wells have declined to 50 pounds.

(2) The rock pressure at which it will become unprofitable for Canadian to drill additional wells in the Texas Panhandle Field.

A study of the producing ability of an average gas well indicates that a total of less than 1,000,000 Mcf. will be produced from an average well between 125 pounds and 50 pounds rock pressure. Assuming a value of 4c per Mcf. at the well for such gas, the total value of gas to be produced between the rock pressures above mentioned will be less than $40,000.00. Deducting the current rate of royalty and severance taxes applicable to such gas would reduce the total amount above to approximately $30,000.00 which would be available for the payment of operating charges and amortizing the cost of the well with its fittings, meter and gathering line. He has heretofore testified that based upon present conditions, the cost of drilling and completing future gas wells with meter, meter house and gathering line, will

be $30,000.00 each. Obviously, the revenue to be anticipated from a well between a rock pressure of 125 pounds and abandonment pressure of 50 pounds is insufficient to pay the cost of operating, maintaining and amortizing the same, without taking into consideration any return on the investment.

Therefore, for the reasons above stated, it is his opinion that 125 pounds rock pressure represents the lowest pressure at which Canadian will be able profitably and economically to drill additional wells in the Texas Panhandle Field, and it may well develop that it will be economical and good business practice to discontinue drilling at a higher pressure.

(3) The number of wells which will be required by Canadian at certain pressures to furnish its estimated markets.

By the use of the back pressure curves referred to above it is estimated that Canadian will require a total of 212 producing gas wells at 125 pounds rock pressure in order to supply the peak obligations reached in the year 1940 of 186,000 Mcf. per day. Hendee's estimates for future years in his Exhibit No. 80 indicate an increasing average day in the peak month up to 216,000 Mcf. per day in 1946. This estimate of required wells is a minimum because of the decreasing ability of wells to produce gas as indicated by the change in back pressure tests heretofore taken on the same wells at different dates. Also, it has been assumed that each new well drilled in the future will be an average well, which may not be realized since a substantial portion of the undrilled acreage of Canadian is indicated by its geologists to be in so-called areas of less than average or low potential.

By the same method of calculation it is estimated that Canadian would be required to drill 78 additional wells in order to meet the same market requirements of 186 million per day betwen a rock pressure of 125 pounds and 100 pounds; likewise, a total of 725 wells would be required to furnish such markets down to a 50-pound rock pressure, and a total of 1,675 wells down to a 25-pound rock pressure.

A total of 212 producing gas wells will permit an ultimate spacing of wells by Canadian of approximately 1,200 acres per well. Generally, such a spacing should so distribute the

Company's wells among its various leases as to automatically provide for proper internal proration. In some instances, however, internal proration as between leases will not permit certain wells to produce at full capacity as allowed by the Railroad Commission, which again serves to make the above estimates of total wells required a minimum rather than a maximum estimate.

It should be emphasized that the 212 wells estimated above will only be able to supply the market requirements referred to so long as the rock pressure of such wells remains at 125 pounds. As the rock pressure declines with subsequent withdrawals, the producing capacity of the 212 wells will decrease in a greater proportion than the rock pressure until the abandonment pressure of 50 pounds rock pressure is reached.

There is attached to Exhibit 254 a back pressure curve which represents the average well of Canadian. It will be noted that there is indicated upon the curve the expected open flow of the average well at 125 pounds pressure, 100 pounds pressure, 50 pounds pressure and 25 pounds pressure. The open flow as indicated represents the maximum producing ability of the wells at the various pressures indicated. The wells, of course, can produce legally only 25% of this amount due to statutory restrictions.

The witness testified on cross-examination that although he had not prepared a formal study with respect to abandonment pressures similar to the study contained in Exhibit 254, that he has at all times kept the matter in mind and is continuously studying the general question of abandonment pressures. (Vol. LXXXVIII, pp. 13214, 13216.) He stated that it was physically possible to produce a well below 50 pounds, and physically they might be produced to zero pounds but that such operations would not be justified economically. (Vol. LXXXVIII, p. 13217.)

The witness' calculations are made upon a value of gas at the well of 4c per Mcf. on a 16.4 pound pressure base. This is the prevailing price in the field and is based upon the amount that is paid generally by producing companies to their royalty owners for the royalty gas. It hasn't fluctuated particularly during the past few years. (Vol. LXXX-

VIII, pp. 13218-13220.) He has assumed that the present value will remain the same until the abandonment pressure of 50 pounds has been reached. He sees no reason for the value of gas to increase particularly in the future. (Vol. LXXXVIII, pp. 13230, 13231.)

His computation is also based upon the fact that wells in the state of Texas are not permitted to produce in excess of 25% of their open flow. He has assumed that this limitation will also continue throughout the period covered by this study. There is no provision in the law for increasing the proportion of the open flow that a well might produce when pressures become low. It is the witness' opinion in any event that no operator should produce a well in excess of 25% of its open flow volume and that this is particularly true when low pressures have been reached for the reason that there is a great deal of difficulty producing wells at low pressures without overproducing them. (Vol. LXXXVIII, pp. 13234-13236.)

The witness further testified that it would be natural to conclude that if regulations permitted the production of a well up to 50% of its open flow, it would be possible to produce under those circumstances twice as much gas as would be produced if the restriction was 25% of its open flow as it is today, but that this would be an absurd assumption for the reason that no well should be produced at the rate of 50% of its open flow, regardless of regulation. (Vol. LXXXVIII, pp. 13237, 13238.)

The witness also reiterated that open flows will decline at a faster rate than that indicated by the back pressure curve. This is true by reason of mechanical failures of the well. That is, the salting of the formation or caving, or mudding off of the formation. This does not discredit the back pressure curve. The curve will apply if there is no change in the well bore, but if something happens to the well which will decrease its producing characteristic the curve will not apply. Canadian has already had several mechanical difficulties and in some instances has been unsuccessful in restoring a well to its original open flow. (Vol. LXXXVIII, pp. 13244-13250.)

The witness testified that even if the value of gas at the

mouth of the well became higher than 4c per Mcf. during the period covered by the study, that still he did not believe that wells would be produced below a 50-pound pressure. If gas advanced to 8c at the well this would not mean that the wells would be produced down to 25 pounds. The computations, although based upon 4c per Mcf. for the gas at the well would not provide enough money to pay the cost of operations. The witness had not considered anything at all for return on the investment at the 4c per Mcf. wellhead price. (Vol. LXXXVIII, pp. 13252-13255.)

The witness reiterated that at a 50-pound pressure and a 65 per cent load factor, an average well could be expected to produce 160 Mcf. per day, which volume valued at 4c per Mcf. at the well amounts to approximately $6.50 per day, or approximately $2,375 per year before deductions for royalties and severance taxes. Royalties and severance taxes at the present time and at the average rates, amount to approximately $595 per year. This leaves, therefor, the net sum of $1780 available for operating and maintaining an average well at 50 pounds rock pressure. The operating costs alone, without providing for anything else, have been in excess of $1780 per year; for example in 1933 the operating cost of an average well was $2,661.35; in 1934 it was $2741.58; in 1935 it was $2,477.53; in 1936 it was $2,146.14; in 1937 it was $2,287.84; in 1938 it was $2,173.65; in 1939 it was $2,291.50, and in 1940 it was $2,072.56. (Vol. LXXXVIII, pp. 13265-13267.)

The witness stated in his direct examination:

> "The past and present costs of Canadian River Gas Company for operating and maintaining its producing gas wells do not provide a dependable index for the purpose of measuring the cost of operating and maintaining such wells when they reach rock pressures as low as 50 pounds. Present wells of Canadian River Gas Company have been operating at comparatively high pressures, and therefore, have been free from many operating difficulties which will develop at lower pressures. As the rock pressure of a well decreases, its open flow decreases at a proportionately higher rate. As the open flow decreases, the well is less capable of keeping

itself clean of cavings and free from water, which has a tendency to increase bridging in the hole, flooding and salting in the formation. Moreover, as the wells approach a 50-pound rock pressure, they will be older and the corrosion of casing by water at the formations in which the well is not producing will became a greater problem. Since a well of low open flow capacity is unable to free itself of its accumulated water, it may be necessary in many instances to pump or syphon off such water which will add substantially to the cost of operating and maintaining the wells." (Vol. LXXXVI, pp. 13039, 13040.)

Remaining Life of Texas Panhandle Field as a Source of Supply for Long Distance Pipe Lines

Testimony of R. W. Hendee, Witness for Canadian

R. W. Hendee, who is an engineer and also General Manager of Canadian and whose qualifications have been given heretofore, computed the remaining life of the Texas Panhandle Field.

Hendee's testimony on direct examination is shown in Volume LXXXVI, pp. 13045 to 13049, and in Exhibit 255 at pages 1 to 4 inclusive.

He stated that the probable life of the Texas Panhandle Field as a source of supply for major long distance pipe lines now taking gas from that field depends upon (a) the total recoverable gas reserves, (b) the rate of withdrawal, (c) the rock pressure at which it will become unprofitable to drill additional gas wells in the Texas Panhandle Field in the future, and (d) the abandonment pressure below which it will be unprofitable to operate and maintain the then existing gas wells.

For the purposes of his study, he adopted:

(a) J. D. Thompson Jr.'s estimate of original gas reserves in the field as shown in his Exhibit No. 207;

(b) C. J. Peterson's cumulative past withdrawal figures from the field as shown in his Exhibits Nos. 206 and 206-A for the full period ended December 31, 1940;

(c) Max K. Watson's study of rock pressure at which it will become unprofitable to drill additional gas wells in the Texas Panhandle Field in the future, and

(d) Max K. Watson's abandonment rock pressure of 50 pounds as shown in his Exhibit No. 254.

Estimates of future withdrawals beyond 1940 have been made by the witness, using the same classifications as followed by Peterson, i. e., "Gas Used by Gas Pipe Lines," "Gas Used by Gasoline Plant," "Casinghead Gas Not Treated (Blown in Air)" and "Gas Blown in Air and Used in Drilling Wells," a schedule of the estimated future withdrawals by years together with Peterson's withdrawals being attached to Exhibit 255 as Table I.

With respect to "Gas Used by Gas Pipe Lines," figures were obtained by witness directly from each major pipe line company withdrawing gas from the field.

With respect to "Gas Used by Gasoline Plants" (which includes gas used for the manufacture of carbon black), a study has been made by the witness of the probable trend of operations in the Texas Panhandle Field of the natural gasoline industry and the carbon black industry, and from the information and data gathered in such study the withdrawals of gas for such purposes have been estimated by him for the future.

Studies and estimates have been made by him with respect to "Casinghead Gas Not Treated (Blown in Air)" and "Gas Blown in Air and Used in Drilling Wells."

There is attached to Hendee's Exhibit 255 a production table which is set out in full as follows:

Year	Gas Used By Pipe Lines M.C.F. (1)	Gas Used By Gasoline Plants M.C.F. (2)	Casinghead Gas Not Treated (Blown in Air) M.C.F. (3)	Gas Blown in Air and Used in Drilling Wells M.C.F. (4)	Total Gas Produced M.C.F. (5)	Total Cumulative Gas Produced M.C.F. (6)
1926 and earlier	15,725,533	34,300,000	92,000,000	105,400,000	247,425,533	247,425,533
1927	8,825,598	263,800,000	144,000,000	88,600,000	505,225,598	752,651,131
1928	39,978,176	330,500,000	114,000,000	49,500,000	533,978,176	1,286,629,307
1929	84,767,509	395,110,000	90,000,000	55,800,000	625,677,509	1,912,306,816
1930	81,175,878	412,796,000	70,000,000	52,600,000	616,571,878	2,528,878,694
1931	86,538,708	346,255,000	50,000,000	16,300,000	499,093,708	3,027,972,402
1932	97,087,294	283,708,708	32,940,000	4,026,000	417,762,002	3,445,734,404
1933	109,179,977	333,838,516	25,550,000	4,380,000	472,948,493	3,918,682,897
1934	147,363,215	564,804,621	33,800,000	21,665,125	767,632,961	4,686,315,858
1935	156,695,751	563,734,998	28,850,000	26,037,265	775,318,014	5,461,633,872
1936	183,804,643	330,269,607	15,540,000	30,066,628	559,680,878	6,021,314,750
1937	210,333,095	345,298,466	6,205,000	29,692,496	591,529,057	6,612,843,807
1938	207,553,695	318,498,051	5,075,000	12,268,267	543,395,013	7,156,238,820
1939	222,299,905	329,653,273	7,300,000	13,026,239	572,279,417	7,728,518,237
1940	235,860,805	337,256,848	7,320,000	17,029,475	597,467,129	8,325,985,366
1941	239,538,447	340,000,000	7,300,000	15,000,000	601,838,447	8,927,823,813
1942	257,242,137	345,000,000	7,300,000	15,000,000	624,542,137	9,552,365,950
1943	269,210,846	345,000,000	7,300,000	15,000,000	636,510,846	10,188,876,796
1944	282,697,341	345,000,000	7,300,000	15,000,000	649,997,341	10,838,874,137
1945	291,972,410	345,000,000	7,300,000	15,000,000	659,272,410	11,498,346,547

(The volumes shown above are computed on a pressure base of 16.4 pounds per square inch.)

The above table shows the actual withdrawals from the field as compiled and estimated by Peterson and shown in his Exhibits 206 and 206-A through the year 1940. This table also shows the estimates of future production by Hendee for the years 1941 to 1945 inclusive. Hendee assumes that the production from 1945 to 1956 will be the same on the average as the production in the year 1945, as estimated by him. It will be noted that Hendee estimates that the total production from the field in 1945 will be about 62 billion greater than the total production from the field in 1940, an increase of slightly over 10%. Most of this increase results from the increase in withdrawals by pipe lines which accounts for approximately 56 billion from 1940 to 1945 out of a total overall increase of 62 billion for the same period. In other words, Hendee's estimates anticipates practically no increase in the withdrawals from the Panhandle Field except the increase in withdrawals by the pipe line companies.

Hendee stated that the annual actual and estimated withdrawals had been combined in cumulative totals and then plotted against Thompson's estimated total recoverable gas reserves on a curve entitled "Total Cumulative Past and Estimated Future Withdrawals from Texas Panhandle Field," which is attached to Exhibit 255 as Chart "A." Since no estimates covering future withdrawals beyond the year 1945 were made, the plotted curve was extended beyond 1945 at approximately the 1945 withdrawal rate until the curve intercepted Thompson's estimated recoverable gas reserves at a rock pressure of 100 pounds.

Watson has shown in his Exhibit No. 254 that it will be unprofitable to drill gas wells in the Texas Panhandle Field with rock pressures of 125 pounds or less. Therefore, it is reasonable to expect that drilling of new wells in the field will have ceased when the average field pressure has declined to 100 pounds. Watson has also shown in his Exhibit No. 254 that commercial production of gas by the major pipe line companies will cease when the average field pressure has declined to 50 pounds. Since it is assumed that drilling will cease at an average field pressure of 100 pounds, it follows that the productive capacity of existing wells will decline progressively down to the assumed abandonment pressure which results in declining annual withdrawals for this period as indicated on the plotted curve.

By applying in this manner the past and estimated future gas withdrawals against Thompson's recoverable gas reserves in the field, the curve which witness had plotted indicated that average field pressures will have reached Watson's abandonment pressure of 50 pounds and the economic life of the field as a source of supply for major long distance gas pipe lines will terminate by the end of the year 1956.

There is attached to Exhibit 255 a curve showing the total cumulated past and estimated future withdrawals from Texas Panhandle Field. This curve shows that when an average pressure of 100 pounds has been reached in the field that there will have been produced a total in excess of 15 trillion cubic feet of gas based upon Thompson's estimate as contained in Exhibit 207, and that when an average pressure of 50 pounds has been reached the total production from the field will be 17,381,014,589 Mcf. on a 16.4 pounds pressure base. This corresponds to Thompson's estimate of original gas in place at an assumed abandonment pressure of 50 pounds per square inch gauge but before the application of Thompson's recovery factor of 90 per cent.

Hendee testified on cross examination that he began collecting information for his Exhibit 255 in January, 1940, although he had been generally familiar with production in the Texas Panhandle Field for the past twenty years and particularly familiar with the question since assuming his present position about five years ago. (Vol. LXXXVIII, p. 13287.) He estimated the production from 1940 to 1945 and used the 1945 estimated production figure for the remainder of the period covered by his study, that is, up to 1956, at which time the average field pressures will have reached an abandonment pressure of 50 pounds and the economic life of the field as a source of supply for major long distance gas pipe lines will expire at that time. The witness has estimated that the withdrawals will continue at the same rate as the 1945 estimated withdrawals until the curve shown in Exhibit 255 intersects the 100-pound reserve estimate of Thompson and that the withdrawals will be tapered off somewhat until the 50-pound abandonment pressure has been reached. (Vol. LXXXVIII, pp. 13288, 13289.)

The witness was accused of having testified on a previous

occasion in this case that the life of the Canadian River-Colorado Interstate project would terminate in 1947, which is the date that most of the contracts expire. He stated positively that he didn't testify to that effect but merely testified that he didn't know what would happen after the contracts expired in 1947. (Vol. LXXXVIII, pp. 13289, 13290.)

In this Exhibit 255 the witness considered the withdrawals from the entire field and didn't consider the withdrawals of Canadian alone for the reason that the life of Canadian as a gas producer is dependent generally on the life of the field, and that his study had to do primarily with the life of major long distance gas pipe lines. (Vol. LXXXVIII, pp. 13291, 13292, 13294.) There will be some gas produced after the long distance pipe lines are no longer operating in the field. This gas will be utilized locally. (Vol. LXXXVIII, p. 13295.)

The witness has assumed that gas withdrawals will remain about the same from 1945 to 1956. However, the general trend of withdrawals has been upward, but he has given no consideration to this in determining the future life of the field. (Vol. LXXXVIII, pp. 13300, 13301.) The witness has had some experience in estimating future withdrawals and in fact had estimated the 1940 production and had missed it only one-tenth of 1 per cent. (Vol. LXXXVIII, pp. 13301, 13302.)

In estimating the future withdrawals of the pipe line companies operating in the field he simply took the estimates of the executives of the various companies. In other words, he utilized the estimates of the respective companies as to their future withdrawals for 1940 to 1945. (Vol. LXXXVIII, pp. 13303, 13304, 13305, 13331.)

In estimating the withdrawals by gasoline plants the witness made a particular study of the gasoline industry, the carbon black industry and related industries. This study was based primarily upon the Minerals Year-Book issued by the Bureau of Mines and he also studied the past production or withdrawals of the gasoline plants and carbon black plants in the field. The withdrawals for these purposes have been fairly constant for the past few years except for the years 1934 and 1935 when the Stripping Law

was in effect. After that, and beginning in 1936, the withdrawal figures have been fairly constant. No two years have been actually the same but he would not expect them to be. The witness also discussed the matter generally with a great many people and read numerous articles dealing with gasoline plants, carbon black plants and pipe lines. He didn't write to the executives of companies owning gasoline plants as he did to the companies owning gas pipe lines for the reason that the gasoline plants were running at about their capacity and it would follow that their production for the future would not vary a great deal from the production at present although the general condition in the industry indicates that the production of both carbon black and gasoline will continue to increase. (Vol. LXXXVIII, pp. 13334-13343.) Reference to the table of gas withdrawals incorporated in Exhibit 255 will show that after 1941 the witness makes no change whatever in the estimated use of gas by gasoline plants and upon being questioned concerning this he stated that this represented a very fair average figure for the future and that he didn't think it would be much more or less than that. (Vol. LXXXVIII, p. 13345.)

His estimates for casinghead gas not treated and blown in the air are virtually the same from 1938 for the reason that the witness feels that the wastage of gas of this character is about as low as it can possibly get. There was a great decrease in gas of this character blown into the air from 1934 to 1937 due to more careful operations on the part of the operators in the field but he doesn't think it is possible for it to get any lower than it is now. (Vol. LXXXVIII, pp. 13345-13346.)

The witness is also of the opinion that gas lost in the drilling of wells and gas blown into the air is about as low as it can get. The figures in 1932 and 1933 are very low because there wasn't much drilling during that period and from 1933 to 1937 there was an intensive development which caused the curve to go up. There has been quite a little drilling from 1938 to 1940 but the loss of gas has been better controlled through the utilization of better methods. (Vol. LXXXVIII, p. 13348.)

The curve, as shown in Exhibit 255, tapers off somewhat from the 100 pounds average pressure point to 50 pounds average pressure. That is true because the production will

be a little less during that period, and if he had not tapered off the production during that period, his calculations would have resulted in reaching an abandonment pressure at 50 pounds about two years sooner than his curve indicates. The witness explained that it was perfectly obvious where drilling is discontinued at a pressure of around 100 pounds you will get less and less production from the same wells as the pressure declines. (Vol. LXXXVIII, pp. 13349, 13350.)

The witness testified on redirect examination that he did not estimate the future withdrawals by the gas pipe line companies by extending a curve based upon past performance, but merely took the estimated future withdrawals as given to him by the various companies. If he had made the estimate independent of the figures given to him by such companies it would have been necessary for him to study the markets of the companies, the market outlets and matters of that kind. It would have been necessary for him to have had a great deal more information than is reflected by past sales. (Vol. LXXXVIII, pp. 13352, 13353.)

The principal outlet of gas consumed by gasoline plants is the outlet afforded by carbon black plants. There is nothing at this time that indicates any decrease in the manufacture of carbon black. About 85% of carbon black production is utilized in the rubber industry and this production of rubber in the United States is increasing and will probably continue to increase by reason of the demands brought about by the fact that army units are being mechanized. Carbon black is also used in synthetic rubber to the same degree as it is in natural rubber and the manufacture of synthetic rubber is likely to increase in the immediate future. The demand for motor fuel also affects to some degree the operation of gasoline plants and the present indications are that there will be a tremendous demand for gasoline. The witness, however, in estimating the demands of gasoline plants has not taken this increased demand into account but has assumed that the gasoline plants and carbon black plants will consume the same volume of gas in the future that they have in the past. (Vol. LXXXVIII, pp. 13353, 13355.)

The witness further testified on recross examination that the utilization of sour gas for the manufacture of carbon

black is not necessarily wasteful. Carbon black is a very useful product and is the very best substance *than* can be used in automobile tires in order to increase longevity of the tire and its grip on the road. It is not wasteful to take the gasoline out of the gas since but a very, very small percentage of the gas is lost and it is really an improvement upon the gas that goes in the pipe lines. It really doesn't hurt the gas enough to be of any particular importance. The witness does not know whether the pipe line companies will in the future take sour gas or not but if they do he does not believe that this will materially affect the life of the field since the use of the sour gas for this purpose would merely replace the gas that is now being used for other purposes and the total withdrawals would be about the same. (Vol. LXXXVIII, pp. 13357, 13362, 13364, 13365.)

R. W. HENDEE further testified on cross examination (Vol. 88, pp. 13286-13298; 13309; 13332-13333, and in Vol. 101, pp. 15635-15637) as follows:

Q. Mr. Hendee, your study is predicated upon the soundness of the testimony of three witnesses?

A. Three.

Q. Mr. J. D. Thompson, Jr's. estimate of reserves; C. J. Peterson's cumulative withdrawals and Max K. Watson's study of rock pressure; if you are wrong, they are wrong?

A. That would be correct.

Q. You made a careful study of their exhibits?

A. Yes, I have.

Q. Do you feel competent to pass upon the soundness of their exhibits?

A. No, I don't as I am not a geologist. I have used the exhibits as the best information that I had.

Q. Why didn't you take Mr. Hammer's exhibit, his estimate of reserves, and use it here?

A. Because I prepared this before Mr. Hammer's exhibit was put in in the first place.

Q. You mean if you had been working for the Federal Power Commission you might have done that?

A. I might have.

Q. Now, this study of yours as to future withdrawals in the Texas Panhandle field, how long did it take you to get this information together?

A. I started in January 1940, I believe, collecting the information.

Q. January 1940?

A. That is right.

Q. This is the first sort of study like this you have ever made?

A. Exactly like this, yes.

Q. Have you spent many years studying the withdrawals from the Panhandle Field of Texas?

A. I didn't get your question.

Q. Have you spent many years studying the rates of withdrawals from the Texas Panhandle field?

A. No.

Q. You just cumulated a lot of data and put it together and here it is?

A. No, I wouldn't say that. I have had general experience in the gas business for twenty years and that has naturally been a subject of my interest for a good many years. I have been interested in the Panhandle field, although I have only been in my present position about five years.

Q. During that five-year period, however, you have made no study as to the withdrawals from the field?

A. No, I don't think I have.

Q. And is this study made specifically for this case or not?

A. It was made specifically for this case.

Q. Is your company relying upon this exhibit to govern its future conduct in the operations of your company?

A. I think so, yes, sir.

Q. You think they are?

A. Yes.

Q. What makes you believe that?

A. Well, I think that is the best information we have at the present.

Q. At the present?

A. Yes, sir.

Q. Do you think it is a good indication of what will be the situation in 1956?

A. I think this is an estimate and I think it is the best estimate we can make and the best one available at the time.

Q. As I understand, you don't make an estimate all the way to 1956 but just to 1945?

A. That is correct.

Q. What happens with your 1956 proposition here? You state here at the end of your exhibit: "The curve which I have plotted indicates that average field pressures will have reached Mr. Watson's abandonment pressure of 50 pounds and the economic life of the field as a source of supply for major long distance gas pipe lines will terminate by the end of the year 1956."

A. Where are you reading?

Q. On the last page of your written statement.

The Trial Examiner: It is Page 4, Mr. Hendee.

The Witness: What was the question?

By Mr. March:

Q. My question is, if you have just made your estimate to 1945, how can you make this statement about 1956?

A. I have assumed for the purpose of this exhibit that the withdrawals will continue at the same rate until the curve intersects Mr. Thompson's 100-pound reserve and it has been tapered off to the 50-pound line. That is all there has been done.

Q. So your real estimate is 1945 and you have just extended your curve to 1956 just to see what it would look like?
